LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

National Semiconductor Corporation 2900 Semiconductor Drive, P.O. Box 58090, Santa Clara, California 95052-8090 1-800-272-9959 TWX (910) 339-9240

National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied, and National reserves the right, at any time without notice, to change said circuitry or specifications.

Microcontroller Introduction

Practical Solutions to Real Problems

Microcontrollers have always been driven by customer need rather than technological capability.

They were designed to meet specific needs with specific performance in specific applications with specific cost.

That also meant, however, that your choices were limited to what was available on the market—which meant possibly having to compromise your design objectives because you couldn't get exactly the microcontroller you needed.

No more.

Now you can get a microcontroller from National that spans a wide range of system solutions—to go almost anywhere your design imagination takes you.

Whether you need a low-cost 4-bit workhorse or a 16-bit 30 MHz powerhouse, whether you want 1/2 kbyte of ROM or over 64 kbytes, whether you're building a simple singing greeting card or a complex telecommunications network, we have a microcontroller for the job.

With on-board CPU, memory, internal logic, and I/Os, National microcontrollers are helping more and more designers lower system costs and shrink system size.

And as technology brings more peripheral functions onto the chip, including user-programmable memory, fast SRAM, timers, UARTs, comparators, A/D converters, and LAN interfaces, the microcontroller will become the cost-efficient choice for even such real-time "microprocessor" applications as laser printers, ISDN, and digital signal processing.

That's why National continues to lead the industry in the development of microcontroller technology.

That's why we have 8-bit and 16-bit controller cores.

That's why we're scaling our common M²CMOSTTM process for submicron feature sizes, hypermegahertz frequencies, and unparalleled performance levels.

That's why we offer you "Hot-Line" applications support and a 24-hour-a-day digital information service.

That's why we offer you MS DOS-based development tools and high-level-language (C) compilers

And that's why we've committed the full resources of our company to provide you with the most complete, most reliable, most cost-effective systems solution for all your needs.

This databook is a reflection of that commitment.

It will give you an overview of microcontrollers in general and of National's microcontrollers in particular.

It will help you evaluate your microcontroller options from both a business perspective and an engineering perspective.

It will help you make reasoned judgements about selecting the best microcontroller for your needs.

And it will show you what the microcontroller future holds in store for all of us.

If you'd like more information, or you'd like to find out how to put a microcontroller to work in your own application, just contact your local National Semiconductor Sales Office.

How to Select a Microcontroller

Microcontrollers have evolved far beyond their origins as control chips in calculators.

Today, microcontrollers can be the perfect solution for simplifying a wide range of designs. And for giving those designs a clear competitive advantage in the marketplace.

Whether used for simple logic replacement or as an integral part of a high performance system, a microcontroller can reduce system costs, shrink system size, and shorten system design cycles. And yet deliver performance often superior to "traditional" digital solutions.

Still, all microcontrollers are not created equal. And it's important to consider a number of factors before committing to a particular device:

1. Is the microcontroller optimized for your specific application in terms of speed, performance, features, and cost?
2. Is it code-efficient, and based on a true microcontroller architecture for the highest performance and efficiency?

3. Is it fabricated in the most advanced CMOS process technology, and is it fully scalable to maintain its performance edge in the future?

4. Is it supported by a comprehensive family of development tools that run on standard platforms such as the IBM-PC?

5. Is it backed by a dedicated team of professionals who are available not only to provide expert training for new users, to get them on-line quickly and efficiently, but also to provide technical guidance for even the most experienced user?

6. Is it designed for the future, with the capability of expanding on-chip functionality.

If you answered "yes" to all these questions, then you already know that there's only one company with the product depth and technology capability to provide you with a microcontroller optimized for your specific application.

National Semiconductor.

You'll find National Microcontrollers in:

Laser Printers
 Disc Controllers
 Telecommunications Systems
 Keyboards
 Airplane Multiplex Systems
 Car Radios
 Engine Control Systems
 Anti-Skid Brake Systems
 Armaments
 Factory Automation
 Medical Equipment
 Fuses
 Scales
 Refrigerators
 Security Systems
 Garage Door Openers
 Camera Aperture Controls
 Office Copiers
 Cable TV Converters
 Televisions
 Video Recorders
 Solar Heating Controls
 Thermostats
 Climate Control Systems
 Intelligent Toys
 Kitchen Timers

Why Select a National Microcontroller

National has created the most complete selection of 4-, 8-, and 16-bit microcontrollers of any company in the industry.

Which means that no matter what the specific needs of your application are, you can find a National microcontroller to meet them.

Our COP400 family offers the lowest-cost, 4-bit solutions for timing, counting, and control functions.

Our COP800 family offers low-cost, feature-rich, 8-bit solutions.

And our High Performance microController (HPC™) family offers the highest performance with the world's fastest 16-bit CMOS solution.

Microcontroller Family of Products

TL/XX/0071-1

With a full range of performance- and feature-options, National's microcontroller families can be customized to meet the needs of your specific application.

1.0 COMMON FEATURES FOR A CUSTOM FIT

All our microcontrollers are designed to provide not just a one-time-only solution, but a continuum of solutions to meet the changing demands of your product and the marketplace.

Our COP400 family, for example, which consists of over 60 devices, is designed with a common instruction set, so you can migrate from one member of the family to others without having to recode, so you can take efficient advantage of the application-specific flexibility of the COP400 family's programmable I/O options.

Our COP800 and HPC families, on the other hand, are each designed around a common CPU core that then can be surrounded by a variety of standard functional building blocks such as RAM, ROM, user programmable memory, fast SRAM, DMA, UART, comparator, A/D, HDLC, and I/O.

This unique core approach allows us to offer you a microcontroller with the exact combination of CPU power and peripheral function you need for your specific application. So you don't have to compromise your design parameters by using an inappropriate device, and you don't have to compromise your cost parameters by paying for performance and features you don't need.

This core concept also allows us to bring new microcontroller products to market fast and at a lower cost to help you keep pace with the rapidly changing conditions in your own market.

And it allows us to implement designs for both the COP800 and the HPC cores, for the highest levels of integration and flexibility in your own proprietary design.

COP400 Post-Metal ION Implant

TL/XX/0071-2

2.0 TRUE MICROCONTROLLER ARCHITECTURE

Our microcontrollers are designed as true controllers, not modified microprocessors.

The COP400 family is designed with a two-bus Harvard architecture; the COP800 family with a memory-mapped, modified Harvard architecture, and the HPC family with a memory-mapped, von Neumann architecture.

All three control-oriented families, however, are optimized for high code efficiency. Most instructions are only 1 byte long—yet each can typically execute several functions. This “function-dense” code provides a substantial increase in memory efficiency and processing speed.

3.0 ADVANCED PROCESS AND PACKAGING TECHNOLOGIES

National offers you not only the right microcontroller for your needs, but also the right process technology for your microcontroller.

COP400 devices are available in both high-speed NMOS and low-power CMOS fabrications, while the higher-performance COP800 and HPC families are both fabricated in National's advanced M²CMOS process.

M²CMOS. This double-metal CMOS process offers significant design advantages. It combines the speed of NMOS, the ruggedness of bipolar, and the low power consumption of bulk CMOS to produce fast, dense, highly efficient, highly scalable devices for a wide variety of integrated-circuit designs.

It's for these reasons that M²CMOS has become the standard process technology for all of National's advanced-

technology LSI and VLSI products, including microprocessors, gate arrays, standard cells, telecommunications devices, linear devices and, of course, microcontrollers.

Post-Metal Programming (PMP). This is a new process technology available from no other semiconductor manufacturer in the world. It offers the fastest, guaranteed prototype programmed-ROM turn-time in the industry.

PMP is a high-energy implantation process that allows microcontroller ROM to be programmed **after** final metallization.

This is a true innovation, because ROM is usually implemented in the second die layer, with nine or ten other layers then added on top. And that means the ROM pattern must be specified early in the production process, and completed prototype devices won't be available typically for six weeks.

With PMP, however, dice can be fully manufactured through metallization and electrical tests (only the passivation layers need to be added), and held in inventory. Which means ROM can be programmed late in the production cycle, **making prototypes available in only two weeks!**

PMP allows you to adapt to fast-changing market conditions and to take maximum advantage of narrow windows of opportunity.

And shorter production lead times can simplify your inventory control and reduce safety stock by up to 20%, giving you significant cost reductions.

Currently, Post-Metal Programming is available for selected members of the COP400 family, and will be expanded to the COP800 and HPC families in the near future.

Military versions. All National microcontrollers have CMOS parts available in the full military temperature range (-55°C to $+125^{\circ}\text{C}$).

In addition, parts are available that have been certified under MIL-STD-883, Rev. C, the most rigorous non-JAN screening flow in the electronics industry.

Packaging. One major reason that National microcontrollers demonstrate such consistently high levels of reliability is that we've developed special advanced packaging processes to protect the die.

For example, we've designed a unique leadframe with "locking holes" that helps block any penetrating moisture from reaching the die itself.

And the leadframes themselves are made of an unusual high-strength copper alloy that has a lower thermal resistance (θ_{JA}) than typical Alloy 42-leadframes.

We've also employed a unique low-stress, high-purity epoxy molding compound for our packages, which gives them a coefficient of expansion that nearly matches that of the leadframes. As a result, many of our microcontrollers are also offered in plastic packages for military-temperature-range operation.

Reliability is built-in at the die level as well. Our M²CMOS microcontrollers are fabricated on dedicated lines at our world-class, six-inch wafer-fab facility in Arlington, Texas. With its Class-10 clean rooms and automated-handling system, Arlington has set a standard of reliability equalled by few other companies in the industry.

And this reliability is available to you in a wide variety of microcontroller packages, ranging in size from 20 to 84 pins.

Package types include plastic and ceramic DIPs, small outline (S.O.) surface mounts, plastic and ceramic leaded chip carriers, and pin grid arrays.

Or, you can select the world's most advanced, high-density packaging option, TapePak™.

TapePak combines the advantages of an automated tape-and-reel-type delivery system with built-in testing pads for reliability and a unique plastic package carrier. The result is a surface-mounted package that can be as small as $\frac{1}{10}$ the size of conventional surface mounts, with lead spacings of 20 mils.

4.0 FULL DEVELOPMENT SUPPORT

Even the right microcontroller, of course, is useless without the right development tool to put that controller to work in your application.

That's why National offers you a full range of development support. Ready-to-run evaluation boards. Emulators. Software. Prototyping devices. Training and seminars for beginning and advanced users. Everything you need to take your design from concept to reality.

And you don't need an expensive, dedicated, development environment to do it. With our development systems, a standard IBM PC becomes a full-featured platform.

And with our comprehensive library of prewritten routines, from keyboard scanners to Fast Fourier Transforms, you can reduce software programming to a minimum. This "user-friendly" service can help you bring your design to market quickly and cost-effectively.

5.0 FULL APPLICATIONS SUPPORT

At National, we believe that applications support should be immediate and "hands-on".

That's why we established the unique Dial-A-Helper program.

With a computer, modem, and telephone, you can tie directly into our Microcontroller Applications Group for fast, direct assistance in developing your design.

You can leave messages on our electronic bulletin board for our Applications Engineers, who will respond to you directly. You can access applications files.

You can download those files for later reference.

Or, if you're having a real problem, you can actually turn the control of your Microcontroller On-Line Emulator development system over to our engineering staff, who can perform remote diagnostic routines to locate and eliminate any bugs.

The point is, when you buy a microcontroller from National, you're buying more than silicon—you're buying the commitment of an entire company of dedicated professionals who share a single goal: to help you put that silicon to **work**.

6.0 THE FUTURE

National's microcontrollers were designed to meet two objectives: to adapt to your evolving needs, and to adapt to evolving technology.

Both "evolutions," however, are leading to the same goal: the complete "system-on-chip" solution.

The key to achieving this goal, of course, is a common, advanced, scalable process technology.

That's why both the COP800 and HPC families are fabricated in our high-performance double-metal CMOS process. This is a highly scalable technology that can accommodate die shrinks to submicron feature sizes, increasing performance and cutting power consumption with each step.

Moreover, because M²CMOS is now the standard process technology for all new National LSI and VLSI devices, the COP800 and HPC cores are able to support one of the broadest range of functional blocks available from any semiconductor manufacturer—all aligned on the same set of design rules.

So you can standardize your designs on just one or two core processors, and, as we introduce new technologies and functions, you can maintain that design knowledge base while taking advantage of these new, higher levels of functional integration.

And because National gives you the option of using standard parts or designing with our functional blocks—both supported by common design tools and a common process—you can create highly competitive, highly secure, highly optimized solutions in minimal space at minimal cost in minimal time.

And that's the name of the game.

Product Status Definitions

Definition of Terms

Data Sheet Identification	Product Status	Definition
Advance Information	Formative or In Design	This data sheet contains the design specifications for product development. Specifications may change in any manner without notice.

The 4-Bit COP400 Family: Optimized for Low-Cost Control

National's COP400 family offers the broadest range of low-priced, 4-bit microcontrollers on the market.

Key Features

- High-performance 4-bit microcontroller
- 4 μ s–16 μ s instruction-cycle time
- ROM-efficient instruction set
- On-chip ROM from 0.5k to 2k
- On-chip RAM from 32 x 4 to 160 x 4
- More than 60 compatible devices in family
- Common pin-outs
- NMOS and P²C²MOS™
- MICROWIRE™ serial interface
- Wide operating voltage range: +2.4V to +6.3V
- Military temp range available: –55°C to +125°C
- 20- to 28-pin packages
(incl. 20-, 24-pin SO and 28-pin PLCC)

And far from being "old technology," 4-bit microcontrollers are meeting significant market needs in more applications than ever before. In fact, National shipped more than 40 million 4-bit devices last year alone. The reason for the continuing strength of the COP400 family is its versatility. You can select from over 60 different, compatible devices. The first under 50¢ microcontroller set a new standard of value for cost/performance. You can select devices with a wide variety of ROM and RAM combinations, from 0.5k ROM and 32 x 4 RAM to 2k ROM and 160 x 4 RAM.

And every COP400 family member shares the same powerful, ROM-efficient instruction set and the same pin-out, so you can migrate between devices without re-engineering.

And like all of National's microcontrollers, the COP400 can be optimized to meet your specific application needs, with a variety of I/O options, pin-outs, and package types, from DIPs to SMDs.

COPST™ microcontrollers can be used to replace discrete logic in high-volume consumer products and low-volume industrial products allowing you to add features, miniaturize and reduce component count.

Key Applications

- Consumer electronics
- Automotive
- Industrial control
- Toys/games
- Telephones

Wide Acceptance

COPS wide acceptance comes from innovative products. National has built on this established family with continued and enhanced devices.

- The first under-a-dollar microcontroller led to a broader range of automotive and consumer applications.
- The first high-speed, low-power CMOS microcontrollers with 0.5k ROM provides design flexibility at low cost.
- The first microcontroller implementing MICROWIRE/PLUST™ allowing two-way communication across only three lines.
- The first microcontroller implementing Post-Metal Programming (PMP™) for quick turns prototyping and production.

PMP

Post-Metal Programming (PMP), another NSC microcontroller first. Takes advantage of:

- Seasonal or volatile market demand
- Narrow windows of opportunity in highly competitive markets
- Simplified inventory control
- Reduced safety stock

Get all the advantages of custom-programmed microcontrollers with all the business advantages of low cost, quick-turn prototyping and production.

The secret is an entirely new process technology called Post-Metal Programming.

PMP (Continued)**INSIDE PMP**

Post-Metal Programming is a high energy implantation process that allows the ROM layer of a microcontroller to be programmed after final metallization. That means every die layer can be fully fabricated, except for the passivation layers, and held in inventory. Then when you request a ROM pattern, a ROM implant mask is generated and the buried ROM layer is programmed with an ion beam.

The wafer is passivated and cut into dice which are then packaged on a quick-turn line.

So in as little as two weeks, you've got prototypes.

See COP400 Family of Microcontroller selection

4-WEEK PRE-PRODUCTION QUANTITIES

Wafer fab accounts for the majority of prototyping and production time for integrated circuits.

With PMP, however, the dice are essentially complete and in inventory.

So we can take your approved prototypes right into full production or small quantity pre-production in as little as four weeks.

WINNING THE TIME-TO-MARKET RACE

The electronics market won't wait for anyone. If your competitors make a move, you've got to respond now.

You can't wait around for proof-of-design prototypes. Even a week can make a difference between success or failure. Between gaining market share or losing it. Between staying ahead of the other guys or falling behind. With PMP, you can stretch that lead by *weeks*. In fact, if you compare the quick-turn PMP process to conventional prototype-and-production timetables, you'll see that *you can actually gain as much as 3 1/2 months over your competitors!*

NO EXTRA COST

PMP is available at *no extra cost*.

Compare that with the traditional "alternative" for quick-turn prototyping of user-programmable ROM. EPROM and EEPROM can easily drive your unit costs up to as much as \$6!

And when you consider the additional cost-savings of being able to reduce your safety stock in inventory, knowing you can get quick-turns in a few weeks, the PMP process and

National Semiconductor microcontrollers not only make good *engineering* sense, they make good *business* sense.

System Solutions

The COP400 family provides a flexible, cost-effective system solutions to all applications requiring timing, counting, or control functions.

And, bottom line, if a 4-bit controller can do the job, why pay more?

Development Support**DEVELOPMENT SYSTEM**

The Microcomputer On-Line Emulator Development System is a low cost development system and emulator for COPs microcontroller products. The Development System consists of a BRAIN Board, Personality Board and optional host software.

The purpose of the COP400 Development System is to provide the user with a tool to write and assemble code, emulate code for the target microcontroller and assist in both software and hardware debugging of the system.

It is a self contained computer with its own firmware which provides for all system operation, emulation control, communication, PROM programming and diagnostic operations. It contains three serial ports to optionally connect to a terminal, a host system, a printer or a modem or to connect to other Development Systems in a multi-Development System environment.

The Development System can be used in either a stand alone mode or in conjunction with a selected host system using PC-DOS communicating via a RS-232 port.

See AN-456 for more information.

HOW TO ORDER

To order a complete development package, select the section for the microcontroller to be developed and order the parts listed.

Microcontroller	Order Part Number	Description	Includes	Manual Number

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information System and additionally, provides the capability of remotely accessing the MOLE development system at a customer site.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

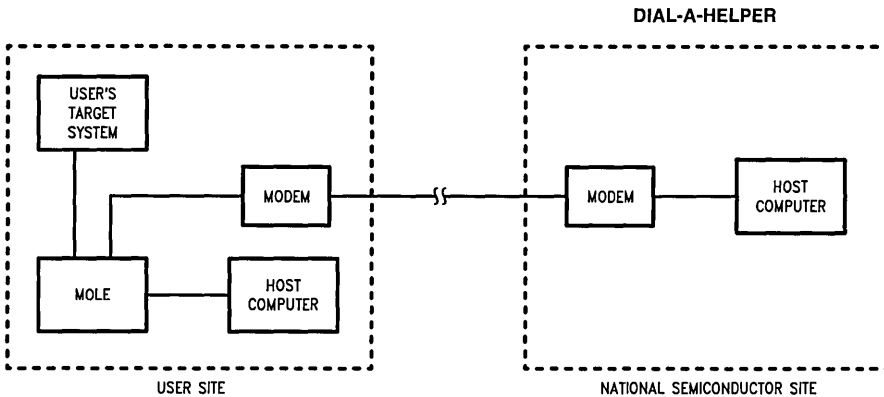

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

Order P/N: MOLE-DIAL-A-HLP
 Information System Package Contains
 DIAL-A-HELPER Users Manual P/N
 Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user is having difficulty in operating a MOLE, he can leave messages on our electronic bulletin board, which we will respond to, or under extraordinary circumstances he can arrange for us to actually take control of his system via modem for debugging purposes.

- Voice: (408) 721-5582
- Modem: (408) 739-1162
- Baud: 300 or 1200 baud
- Set-Up: Length: 8-bit
- Parity: None
- Stop bit: 1
- Operation: 24 hrs., 7 days

TL/XX/0072-1

COP224C/COP225C/COP226C/COP244C/COP245C Single-Chip 1k and 2k CMOS Microcontrollers

General Description

The COP224C, COP225C, COP226C, COP244C and COP245C fully static, Single-Chip CMOS Microcontrollers are members of the COPSTM family, fabricated using double-poly, silicon gate microCMOS technology. These Controller Oriented Processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP224C and COP244C are 28 pin chips. The COP225C and COP245C are 24-pin versions (4 inputs removed) and COP226C is 20-pin version with 15 I/O lines. Standard test procedures and reliable high-density techniques provide the medium to large volume customers with a customized microcontroller at a low end-product cost. These microcontrollers are appropriate choices in many demanding control environments especially those with human interface.

Features

- Lowest power dissipation (600 μ W typical)
- Fully static (can turn off the clock)
- Power saving IDLE state and HALT mode
- 4.4 μ s instruction time
- 2k x 8 ROM, 128 x 4 RAM (COP244C/COP245C)
- 1k x 8 ROM, 64 x 4 RAM (COP224C/COP225C/COP226C)
- 23 I/O lines (COP244C and COP224C)
- True vectored interrupt, plus restart
- Three-level subroutine stack
- Single supply operation (4.5V to 5.5V)
- Programmable read/write 8-bit timer/event counter
- Internal binary counter register with MICROWIRE™ serial I/O capability
- General purpose and TRI-STATE® outputs
- LSTTL/CMOS output compatible
- Software/hardware compatible with COP400 family
- Military temperature (-55°C to +125°C) operation

Block Diagram

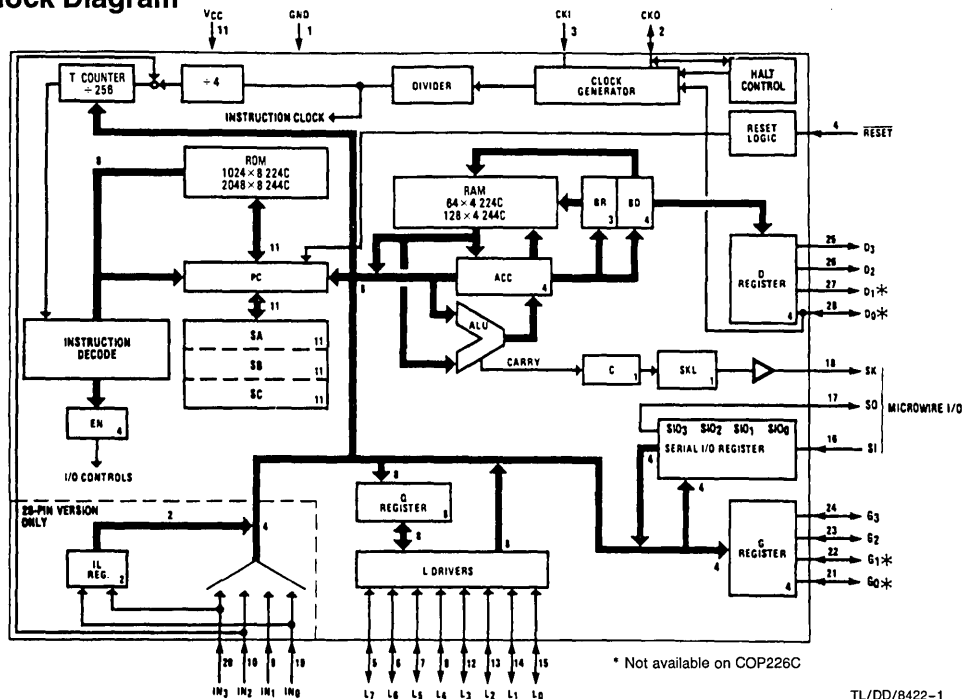

FIGURE 1

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	6V
Voltage at any Pin	-0.3V to $V_{CC} + 0.3V$
Total Allowable Source Current	25 mA
Total Allowable Sink Current	25 mA
Total Allowable Power Dissipation	150 mW

Operating Temperature Range	-55°C to +125°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (soldering, 10 seconds)	300°C

Note: *Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.*

DC Electrical Characteristics -55°C ≤ T_A ≤ +125°C, +4.5V ≤ V_{CC} ≤ +5.5V unless otherwise specified

Parameter	Conditions	Min	Max	Units
Operating Voltage		4.5	5.5	V
Power Supply Ripple (Notes 4, 5)	Peak to Peak		0.25 V_{CC}	V
Supply Current (Note 1)	$V_{CC} = 5.0V$, $t_c = 4.4 \mu s$ (t_c is instruction cycle time)		5	mA

Inputs: (See Figure 3) (Note 4) t_{SETUP}	G Inputs SI Input All Others	$t_c/4 + 0.8$		μs
				μs
				μs
				μs
t_{HOLD}		0.4		μs
Output Propagation Delay t_{PD1} , t_{PD0}	$V_{\text{OUT}} = 1.5\text{V}$, $C_L = 100\text{ pF}$, $R_L = 5\text{k}$		1.4	μs

Note 1: Supply current is measured after running for 2000 cycle times with a square-wave clock on CKI, CKO open, and all other pins pulled up to V_{CC} with 5k resistors. See current drain equation.

Note 2: The HALT mode will stop CKI from oscillating in the RC and crystal configurations. Test conditions: all inputs tied to V_{CC} , L lines in TRI-STATE mode and tied to ground, all outputs low and tied to ground.

Note 3: When forcing HALT, current is only needed for a short time (approx. 200 ns) to flip the HALT flip-flop.

Note 4: This parameter is not tested but guaranteed by design. Variation due to the device included.

Note 5: Voltage change must be less than 0.25 volts in a 1 ms period.

Note 6: SO output sink current must be limited to keep V_{OL} less than 0.2 V_{CC} when part is running in order to prevent entering test mode.

Pin Descriptions

Pin	Description	Pin	Description
L7-L0	8-bit bidirectional port with TRI-STATE	SK	Logic controlled clock output
G3-G0	4-bit bidirectional I/O port	CKI	Chip oscillator input
D3-D0	4-bit output port	CKO	Oscillator output, HALT I/O port or general purpose input
IN3-IN0	4-bit input port (28 pin package only)	RESET	Reset input
SI	Serial input or counter input	V _{CC}	Most positive power supply
SO	Serial or general purpose output	GND	Ground

Functional Description

The internal architecture is shown in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1", when a bit is reset, it is a logic "0".

Caution:

The output options available on the COP224C/225C/226C and COP244C/245C are not the same as those available on the COP324C/325C/326C, COP344C/345C, COP424C/425C/426C and COP444C/445C. Options not available on the COP224C/225C/226C and COP244C/245C are: Option 2 value 2; Option 4 value 0; Option 5 value 1; Option 9 value 0; Option 17 value 1; Option 30, Dual Clock, all values; Option 32, Microbus™, all values; Option 33 values 2, 4, and 6; Option 34 all values; and Option 35 all values.

PROGRAM MEMORY

Program Memory consists of ROM, 1024 bytes for the COP224C/225C/226C and 2048 bytes for the COP244C/245C. These bytes of ROM may be program instructions, constants or ROM addressing data.

ROM addressing is accomplished by an 11-bit PC register which selects one of the 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 11-bit binary count value.

Three levels of subroutine nesting are implemented by a three level deep stack. Each subroutine call or interrupt pushes the next PC address into the stack. Each return pops the stack back into the PC register.

DATA MEMORY

Data memory consists of a 512-bit RAM for the COP244C/245C, organized as 8 data registers of 16×4 -bit digits.

RAM addressing is implemented by a 7-bit B register whose upper 3 bits (Br) select 1 of 8 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register.

Data memory consists of a 256-bit RAM for the COP224C/225C/226C, organized as 4 data registers of 16×4 -bit digits. The B register is 6 bits long. Upper 2 bits (Br) select 1 of 4 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) are usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or T counter or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instructions based upon the immediate operand field of these instructions.

The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

INTERNAL LOGIC

The processor contains its own 4-bit A register (accumulator) which is the source and destination register for most I/O, arithmetic, logic, and data memory access operations. It can also be used to load the Br and Bd portions of the B register, to load and input 4 bits of the 8-bit Q latch or T counter, to input 4 bits of L I/O ports data, to input 4-bit G, or IN ports, and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions, storing the results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register in conjunction with the XAS instruction and the EN register, also serves to control the SK output.

The 8-bit T counter is a binary up counter which can be loaded to and from M and A using CAMT and CTMA instructions. This counter may be operated in two modes depending on a mask-programmable option: as a timer or as an external event counter. When the T counter overflows, an

Functional Description (Continued)

overflow flag will be set (see SKT and IT instructions below). The T counter is cleared on reset. A functional block diagram of the timer/counter is illustrated in Figure 7.

Four general-purpose inputs, IN3–IN0, are provided.

The D register provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of Bd.

The G register contents are outputs to a 4-bit general-purpose bidirectional I/O port.

The Q register is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are outputted to the L I/O ports when the L drivers are enabled under program control.

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O port. Also, the contents of L may be read directly into A and M.

The SIO register functions as a 4-bit serial-in/serial-out shift register for MICROWIRE I/O and COPS peripherals, or as a binary counter (depending on the contents of the EN register). Its contents can be exchanged with A.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK outputs SKL ANDed with the clock.

EN is an internal 4-bit register loaded by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register:

0. The least significant bit of the enable register, EN0, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN0 set, SIO is an asynchronous binary counter, decrementing its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output equals the value of EN3. With EN0 reset, SIO is a serial shift register left shifting 1 bit each instruction cycle time. The data present at SI goes into the least significant bit of

SIO. SO can be enabled to output the most significant bit of SIO each cycle time. The SK outputs SKL ANDed with the instruction cycle clock.

1. With EN1 set, interrupt is enabled. Immediately following an interrupt, EN1 is reset to disable further interrupts.
2. With EN2 set, the L drivers are enabled to output the data in Q to the L I/O port. Resetting EN2 disables the L drivers, placing the L I/O port in a high-impedance input state.
3. EN3, in conjunction with EN0, affects the SO output. With EN0 set (binary counter option selected) SO will output the value loaded into EN3. With EN0 reset (serial shift register option selected), setting EN3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN3 with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains set to "0".

INTERRUPT

The following features are associated with interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- a. The interrupt, once recognized as explained below, pushes the next sequential program counter address (PC + 1) onto the stack. Any previous contents at the bottom of the stack are lost. The program counter is set to hex address 0FF (the last word of page 3) and EN1 is reset.
 1. EN1 has been set.
 2. A low-going pulse ("1" to "0") at least two instruction cycles wide has occurred on the IN₁ input.
 3. A currently executing instruction has been completed.

FIGURE 3. Input/Output Timing Diagrams (divide by 8 mode)

TL/DD/8422-5

TABLE I. Enable Register Modes — Bits EN0 and EN3

EN0	EN3	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = clock If SKL = 0, SK = 0
0	1	Shift Register	Input to Shift Register	Serial out	If SKL = 1, SK = clock If SKL = 0, SK = 0
1	0	Binary Counter	Input to Counter	0	SK = SKL
1	1	Binary Counter	Input to Counter	1	SK = SKL

Functional Description (Continued)

4. All successive transfer of control instructions and successive LBIs have been completed (e.g. if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed).
- c. Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon popping of the stack. For example, if an interrupt occurs during the execution of ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at hex address 0FF. At the end of the interrupt routine, a RET instruction is executed to pop the stack and return program control to the instruction following the original ASC. At this time, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines should not be nested within the interrupt service routine, since their popping of the stack will enable any previously saved main program skips, interfering with the orderly execution of the interrupt routine.
- d. The instruction at hex address 0FF must be a NOP.
- e. An LEI instruction may be put immediately before the RET instruction to re-enable interrupts.

INITIALIZATION

The internal reset logic will initialize the device upon power-up if the power supply rise time is less than 1 ms and if the operating frequency at CKI is greater than 32 kHz, otherwise the external RC network shown in Figure 4 must be connected to the RESET pin (the conditions in Figure 4 must be met). The RESET pin is configured as a Schmitt trigger input. If not used, it should be connected to VCC. Initialization will occur whenever a logic "0" is applied to the RESET input, providing it stays low for at least three instruction cycle times.

Note: If CKI clock is less than 32 kHz, the internal reset logic (option #29=1) MUST be disabled and the external RC circuit must be used.

FIGURE 4. Power-Up Circuit

TL/DD/8422-6

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, IL, T and G registers are cleared. The SKL latch is set, thus enabling SK as a clock output. Data Memory (RAM) is not cleared upon initialization. The first instruction at address 0 must be a CLRA (clear A register).

TIMER

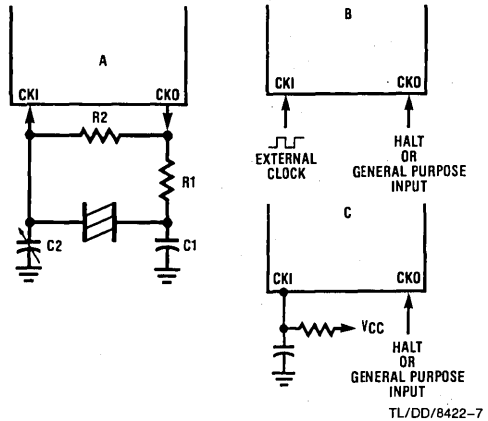

There are two modes selected by mask option:

- a. Time-base counter. In this mode, the instruction cycle frequency generated from CKI passes through a 2-bit divide-by-4 prescaler. The output of this prescaler increments the 8-bit T counter thus providing a 10-bit timer. The prescaler is cleared during execution of a CAMT instruction and on reset.

For example, using a 3.58 MHz crystal with a divide-by-16 option, the instruction cycle frequency of 223.70 kHz increments the 10-bit timer every 4.47 μ s. By presetting the counter and detecting overflow, accurate timeouts between 17.88 μ s (4 counts) and 4.577 ms (1024 counts) are possible. Longer timeouts can be achieved by accumulating, under software control, multiple overflows.

- b. External event counter. In this mode, a low-going pulse ("1" to "0") at least 2 instruction cycles wide on the IN2 input will increment the 8-bit T counter.

Note: The IT instruction is not allowed in this mode.

Crystal or Resonator

Crystal Value	Component Values			
	R1	R2	C1(pF)	C2(pF)
32 kHz	220k	20M	30	6-36
455 kHz	5k	10M	80	40
2.096 MHz	2k	1M	30	6-36
3.6 MHz	1k	1M	30	6-36

RC Controlled Oscillator

R	C	Cycle Time	VCC
30k	82 pF	6-18 μ s	≥ 4.5 V

Note: $15k \leq R \leq 150k$
 $50 \text{ pF} \leq C \leq 150 \text{ pF}$

FIGURE 5. Oscillator Component Values

Functional Description (Continued)

HALT MODE

The COP244C/245C/224C/225C/226C is a FULLY STATIC circuit; therefore, the user may stop the system oscillator at any time to halt the chip. The chip may also be halted by the HALT instruction or by forcing CKO high when it is mask-programmed as a HALT I/O port. Once in the HALT mode, the internal circuitry does not receive any clock signal and is therefore frozen in the exact state it was in when halted. All information is retained until continuing. The chip may be awakened by one of two different methods:

- Continue function: by forcing CKO low, if it mask-programmed as a HALT I/O port, the system clock is re-enabled and the circuit continues to operate from the point where it was stopped.
- Restart: by forcing the $\overline{\text{RESET}}$ pin low (see Initialization).

The HALT mode is the minimum power dissipation state.

CKO PIN OPTIONS

a. Two-pin oscillator—(Crystal). See *Figure 6a*.

In a crystal controlled oscillator system, CKO is used as an output to the crystal network. The HALT mode may be entered by program control (HALT instruction) which forces CKO high, thus inhibiting the crystal network. The circuit can be awakened only by forcing the $\overline{\text{RESET}}$ pin to a logic "0" (restart).

b. One-pin oscillator—(RC or external). See *Figure 6b*.

If a one-pin oscillator system is chosen, two options are available for CKO:

- CKO can be selected as the HALT I/O port. In that case, it is an I/O flip-flop which is an indicator of the HALT status. An external signal can over-ride this pin to start and stop the chip. By forcing a high level to CKO, the chip will stop as soon as CKI is high and CKO output will stay high to keep the chip stopped if

the external driver returns to high impedance state. By forcing a low level to CKO, the chip will continue and CKO will stay low.

- As another option, CKO can be a general purpose input, read into bit 2 of A (accumulator) upon execution of an INIL instruction.

OSCILLATOR OPTIONS

There are three basic clock oscillator configurations available as shown by *Figure 5*.

- Crystal Controlled Oscillator. CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency optionally divided by 4, 8 or 16.
- External Oscillator. The external frequency is optionally divided by 4, 8 or 16 to give the instruction cycle time. CKO is the HALT I/O port or a general purpose input.
- RC Controlled Oscillator. CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is the HALT I/O port or a general purpose input.

Figure 7 shows the clock and timer diagram.

COP245C AND COP225C 24-PIN PACKAGE OPTION

If the COP244C/224C is bonded in a 24-pin package, it becomes the COP245C/225C, illustrated in *Figure 2*, Connection diagrams. Note that the COP245C/225C does not contain the four general purpose IN inputs (IN3–IN0). Use of this option precludes, of course, use of the IN options, interrupt feature, external event counter feature.

Note: If user selects the 24-pin package, options 9, 10, 19 and 20 must be selected as a "2". See option list.

COP226C 20-PIN PACKAGE OPTION

If the COP225C is bonded as 20-pin device it becomes the COP226C. Note that the COP226C contains all the COP225C pins except D₀, D₁, G₀, and G₁.

Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operation symbols used in the instruction set table.

TABLE II. Instruction Set Table Symbols

Symbol	Definition
Internal Architecture Symbols	
A	4-bit accumulator
B	7-bit RAM address register (6-bit for COP224C)
Br	Upper 3 bits of B (register address) (2-bit for COP224C)
Bd	Lower 4 bits of B (digit address)
C	1-bit carry register
D	4-bit data output port
EN	4-bit enable register
G	4-bit general purpose I/O port
IL	two 1-bit (IN0 and IN3) latches
IN	4-bit input port
L	8-bit TRI-STATE I/O port
M	4-bit contents of RAM addressed by B
PC	11-bit ROM address program counter
Q	8-bit latch for L port
SA,SB,SC	11-bit 3-level subroutine stack
SIO	4-bit shift register and counter
SK	Logic-controlled clock output
SKL	1-bit latch for SK output
T	8-bit timer

Instruction Operand Symbols

d	4-bit operand field, 0–15 binary (RAM digit select)
r	3(2)-bit operand field, 0–7(3) binary (RAM register select)
a	11-bit operand field, 0–2047 (1023)
y	4-bit operand field, 0–15 (immediate data)
RAM(x)	RAM addressed by variable x
ROM(x)	ROM addressed by variable x

Operational Symbols

+	Plus
–	Minus
→	Replaces
↔	Is exchanged with
=	Is equal to
\bar{A}	One's complement of A
⊕	Exclusive-or
:	Range of values

Table III provides the mnemonic, operand, machine code data flow, skip conditions and description of each instruction.

OGI	y	33	0011 0011	y → G	None	Output to G Ports Immediate
		5-	0101 y			
OMG		33	0011 0011	RAM(B) → G	None	Output RAM to G Ports
		3A	0011 1010			
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 3)

- Note 1:** All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.
- Note 2:** The ININ instruction is not available on the 24-pin packages since these devices do not contain the IN inputs.
- Note 3:** For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.
- Note 4:** The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.
- Note 5:** A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.
- Note 6:** LBI is a single-byte instruction if d = 0, 9, 10, 11, 12, 13, 14, or 15. The machine code for the lower 4 bits equals the binary value of the "d" data *minus 1*, e.g., to load the lower four bits of B(Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).
- Note 7:** Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)
- Note 8:** For 2K ROM devices, A ↔ Br (0 → A3). For 1K ROM devices, A ↔ Br (0,0 → A3, A2).

Description of Selected Instructions

XAS INSTRUCTION

XAS (Exchange A with SIO) copies C to the SKL latch and exchanges the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. If SIO is selected as a shift register, an XAS instruction can be performed once every 4 instruction cycles to effect a continuous data stream.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 11-bit word PC10:PC8,A,M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC+1 → SA → SB → SC) and replaces the least significant 8 bits of the PC as follows: A → PC7:4, RAM(B) → PC3:0, leaving PC10, PC9 and PC8 unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SC → SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SB → SC, the previous contents of SC are lost.

Note: LQID uses 2 instruction cycles if executed, one if skipped.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the contents of ROM addressed by the 11-bit word, PC10:8,A,M. PC10,PC9 and PC8 are not affected by JID.

Note: JID uses 2 instruction cycles if executed, one if skipped.

SKT INSTRUCTION

The SKT (Skip On Timer) instruction tests the state of the T counter overflow latch (see internal logic, above), executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction allow the processor to generate its own time-base for real-time processing, rather than relying on an external input signal.

Note: If the most significant bit of the T counter is a 1 when a CAMT instruction loads the counter, the overflow flag will be set. The following sample of codes should be used when loading the counter:

```
CAMT ; load T counter
SKT  ; skip if overflow flag is set and reset it
NOP
```

IT INSTRUCTION

The IT (idle till timer) instruction halts the processor and puts it in an idle state until the time-base counter overflows. This idle state reduces current drain since all logic (except the oscillator and time base counter) is stopped. IT instruction is not allowed if the T counter is mask-programmed as an external event counter (option #31 = 1).

INIL INSTRUCTION

INIL (Input IL Latches to A) inputs 2 latches, IL3 and IL0, CKO and 0 into A. The IL3 and IL0 latches are set if a low-going pulse ("1" to "0") has occurred on the IN3 and IN0 inputs since the last INIL instruction, provided the input

pulse stays low for at least two instruction cycles. Execution of an INIL inputs IL3 and IL0 into A3 and A0 respectively, and resets these latches to allow them to respond to subsequent low-going pulses on the IN3 and IN0 lines. If CKO is mask programmed as a general purpose input, an INIL will input the state of CKO into A2. If CKO has not been so programmed, a "1" will be placed in A2. A0 is input into A1. IL latches are cleared on reset. IL latches are not available on the COP245C/225C, and COP226C.

INSTRUCTION SET NOTES

- The first word of a program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, they are still fetched from the program memory. Thus program paths take the same number of cycles whether instructions are skipped or executed except for JID, and LQID.
- The ROM is organized into pages of 64 words each. The Program Counter is a 11-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID, or LQID is the last word of a page, it operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a JID or LQID located in the last word of every fourth page (i.e. hex address 0FF, 1FF, 2FF, 3FF, 4FF, etc.) will access data in the next group of four pages.

Note: The COP224C/225C/226C needs only 10 bits to address its ROM. Therefore, the eleventh bit (P10) is ignored.

Power Dissipation

The lowest power drain is when the clock is stopped. As the frequency increases so does current. Current is also lower at lower operating voltages. Therefore, the user should run at the lowest speed and voltage that his application will allow. The user should take care that all pins swing to full supply levels to insure that outputs are not loaded down and that inputs are not at some intermediate level which may draw current. Any input with a slow rise or fall time will draw additional current. A crystal or resonator generated clock input will draw additional current. For example, a 500 kHz crystal input will typically draw 100 μ A more than a square-wave input. An R/C oscillator will draw even more current since the input is a slow rising signal.

If using an external squarewave oscillator, the following equation can be used to calculate operating current drain.

$$I_{CO} = I_Q + V \times 70 \times F_i + V \times 2400 \times F_i / D_v \quad \text{where:}$$

$$I_{CO} = \text{chip operating current drain in microamps}$$

$$I_Q = \text{quiescent leakage current (from curve)}$$

$$F_i = \text{CKI frequency in MegaHertz}$$

$$V = \text{chip } V_{CC} \text{ in volts}$$

$$D_v = \text{divide by option selected}$$

For example at 5 volts V_{CC} and 400 kHz (divide by 4)

$$I_{CO} = 120 + 5 \times 70 \times 0.4 + 5 \times 2400 \times 0.4 / 4$$

$$I_{CO} = 120 + 140 + 1200 = 1460 \mu\text{A}$$

Power Dissipation (Continued)

If an IT instruction is executed, the chip goes into the IDLE mode until the timer overflows. In IDLE mode, the current drain can be calculated from the following equation:

$$I_{ci} = I_Q + V \times 70 \times F_i$$

For example, at 5 volts V_{CC} and 400 kHz

$$I_{ci} = 120 + 5 \times 70 \times 0.4 = 260 \mu A$$

The total average current will then be the weighted average of the operating current and the idle current:

$$I_{ta} = I_{CO} \times \frac{T_o}{T_o + T_i} + I_{ci} \times \frac{T_i}{T_o + T_i}$$

where: I_{ta} = total average current

I_{CO} = operating current

I_{ci} = idle current

T_o = operating time

T_i = idle time

I/O OPTIONS

Outputs have the following optional configurations, illustrated in *Figure 8*:

- a. Standard — A CMOS push-pull buffer with an N-channel device to ground in conjunction with a P-channel device to V_{CC} , compatible with CMOS and LSTTL.
- b. Open Drain — An N-channel device to ground only, allowing external pull-up as required by the user's application.
- c. Standard TRI-STATE L Output — A CMOS output buffer similar to a. which may be disabled by program control.
- d. Open-Drain TRI-STATE L Output — This has the N-channel device to ground only.

All inputs have the following option:

- e. Hi-Z input which must be driven by the users logic.

All output drivers use two common devices numbered 1 to 2. Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 9* for each of these devices to allow the designer to effectively use these I/O configurations.

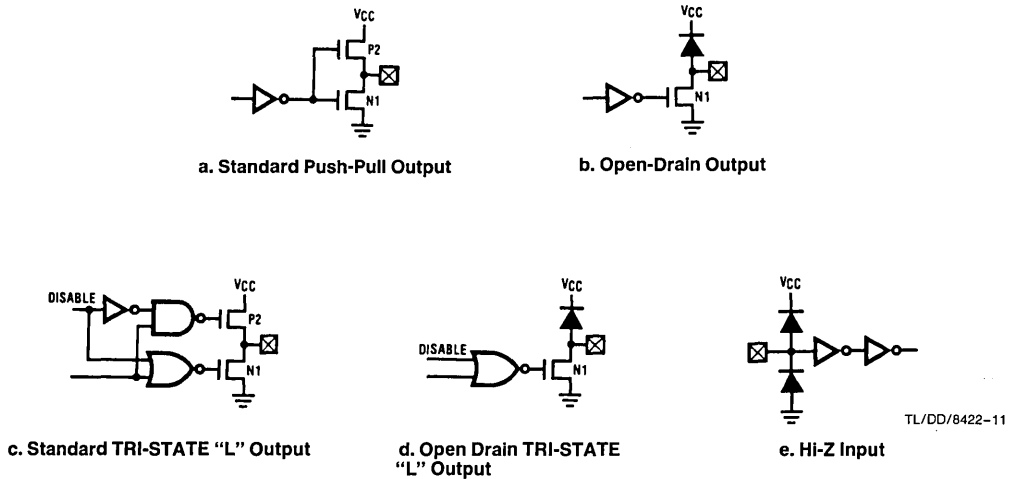

FIGURE 8. Input/Output Configurations

Power Dissipation (Continued)

FIGURE 9. Input/Output Characteristics

Option List

The COP244C/245C/224C/225C/COP226C mask-programmable options are assigned numbers which correspond with the COP244C/224C pins.

The following is a list of options. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

Caution:

The output options available on the COP224C/225C/226C and COP244C/245C are not the same as those available on the COP324C/325C/326C, COP344C/345C, COP424C/425C/426C and COP444C/445C. Options not available on the COP224C/225C/226C and COP244C/245C are: Option 2 value 2; Option 4 value 0; Option 5 value 1; Option 9 value 0; Option 17 value 1; Option 30, Dual Clock, all values; Option 32, Microbus, all values; Option 33 values 2, 4, and 6; Option 34 all values; and Option 35 all values.

PLEASE FILL OUT THE OPTION TABLE on the next page. Photocopy the option data and send it in with your disk or EPROM.

Option 1 = 0: Ground Pin — no options available

Option 2: CKO Pin

- = 0: clock generator output to crystal/resonator
- = 1: HALT I/O port
- = 3: general purpose input, high-Z

Option 3: CKI input

- = 0: Crystal controlled oscillator input divide by 4
- = 1: Crystal controlled oscillator input divide by 8
- = 2: Crystal controlled oscillator input divide by 16
- = 4: Single-pin RC controlled oscillator (divide by 4)
- = 5: External oscillator input divide by 4
- = 6: External oscillator input divide by 8
- = 7: External oscillator input divide by 16

Option 4: $\overline{\text{RESET}}$ input

- = 1: Hi-Z input

Option 5: L7 Driver

- = 0: Standard TRI-STATE push-pull output
- = 2: Open-drain TRI-STATE output

Option 6: L6 Driver — (same as option 5)

Option 7: L5 Driver — (same as option 5)

Option 8: L4 Driver — (same as option 5)

COP410C/COP411C/COP310C/COP311C Single-Chip CMOS Microcontrollers

General Description

The COP410C, COP411C, COP310C, and COP311C fully static, single-chip CMOS microcontrollers are members of the COPSTM family, fabricated using double-poly, silicon-gate CMOS technology. These controller-oriented processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture, and I/O scheme designed to facilitate keyboard input, display output, and BCD data manipulation. The COP411C is identical to the COP410C but with 16 I/O lines instead of 20. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized controller-oriented processor at a low end-product cost.

The COP310C/COP311C is the extended temperature range version of the COP410C/COP411C.

The COP404C should be used for exact emulation.

Features

- Lowest power dissipation (40 μ W typical)
- Low cost
- Power-saving HALT Mode with Continue function
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- 20 I/O lines (COP410C)
- Two-level subroutine stack
- DC to 4 μ s instruction time
- Single supply operation (2.4V to 5.5V)
- General purpose and TRI-STATE® outputs
- Internal binary counter register with MICROWIRE™ compatible serial I/O
- LSTTL/CMOS compatible in and out
- Software/hardware compatible with other members of the COP400 family
- Extended temperature (-40°C to +85°C) devices available
- The military temperature range devices (-55°C to +125°C) are specified on COP210C/211C data sheet.

COP410C/COP411C**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage	6V
Voltage at Any Pin	-0.3V to $V_{CC} + 0.3V$
Total Allowable Source Current	25 mA
Total Allowable Sink Current	25 mA

Operating Temperature Range	0°C to +70°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (Soldering, 10 sec.)	300°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ unless otherwise specified

Parameter	Conditions	Min	Max	Units

Functional Description

To ease reading of this description, only COP410C and/or COP411C are referenced; however, all such references apply equally to COP310C and/or COP311C, respectively.

A block diagram of the COP410C is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1"; when a bit is reset, it is a logic "0".

PROGRAM MEMORY

Program memory consists of a 512-byte ROM. As can be seen by an examination of the COP410C/411C instruction set, these words may be program instructions, program data, or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID, and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words (bytes) each.

ROM ADDRESSING

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by two 9-bit subroutine save registers, SA and SB.

ROM instruction words are fetched, decoded, and executed by the instruction decode, control and skip logic circuitry.

DATA MEMORY

Data Memory consists of a 128-bit RAM, organized as four data registers of 8×4 -bit digits. RAM addressing is implemented by a 6-bit B register whose upper two bits (Br) selects one of four data registers and lower three bits of the 4-bit Bd select one of eight 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) are usually loaded into or from, or exchanged with, the A register (accumulator), they may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3, 15 instruction. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

The most significant bit of Bd is not used to select a RAM digit. Hence, each physical digit of RAM may be selected by two different values of Bd as shown in *Figure 4*. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 to 15, but *not* between 7 and 8 (see Table III).

INTERNAL LOGIC

The internal logic of the COP410C/411C is designed to ensure fully static operation of the device.

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Bd portion of the B register, to load four bits of the 8-bit Q latch data and to perform data exchanges with the SIO register.

The 4-bit adder performs the arithmetic and logic functions of the COP410C/411C, storing its results in A. It also outputs the carry information to a 1-bit carry register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description below.)

The G register contents are outputs to four general purpose bidirectional I/O ports.

The Q register is an internal, latched, 8-bit register, used to hold data loaded from RAM and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The eight L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and RAM.

LL/DD/5015-5

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

Functional Description (Continued)

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter, depending upon the contents of the EN register. (See EN register description below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. With SIO functioning as a serial-in/serial-out shift register and SK as a sync clock, the COP410C/411C is MICROWIRE compatible.

The D register provides four general purpose outputs and is used as the destination register for the 4-bit contents of Bd.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK is a sync clock, inhibited when SKL is a logic "0".

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN3–EN0).

1. The least significant bit of the enable register, EN0, selects the SIO register as either a 4-bit shift register or as a 4-bit binary counter. With EN0 set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN3. With EN0 reset, SIO is a serial shift register, shifting left each instruction cycle time. The data present at SI is shifted into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each instruction cycle time. (See 4, below.) The SK output becomes a logic-controlled clock.
2. EN 1 is not used, it has no effect on the COP410C/411C.
3. With EN2 set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN2 disables the L drivers, placing the L I/O ports in a high impedance input state.
4. EN3, in conjunction with EN0, affects the SO output. With EN0 set (binary counter option selected), SO will output the value loaded into EN3. With EN0 reset (serial shift register option selected), setting EN3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN3 with the serial shift register option selected, disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0".

INITIALIZATION

The internal reset logic will initialize the device upon power-up if the power supply rise time is less than 1 ms and if the operating frequency at CKI is greater than 32 kHz, otherwise the external RC network shown in *Figure 5* must be connected to the $\overline{\text{RESET}}$ pin. The $\overline{\text{RESET}}$ pin is configured as a Schmitt trigger input. If not used, it should be connected to V_{CC} . Initialization will occur whenever a logic "0" is applied to the $\overline{\text{RESET}}$ input, providing it stays low for at least three instruction cycle times.

When V_{CC} power is applied, the internal reset logic will keep the chip in initialization mode for up to 2500 instruction cycles. If the CKI clock is running at a low frequency, this could take a long time, therefore, the internal logic should be disabled by a mask option with initialization controlled solely by $\overline{\text{RESET}}$ pin.

Note: If CKI clock is less than 32 kHz, the internal reset logic (Option 25 = 1) *must* be disabled and the external RC network *must* be present.

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. Data memory (RAM) is not cleared upon initialization. The first instruction at address 0 must be a CLRA (clear A register).

TL/DD/5015-6

$RC > 5 \times \text{Power Supply Rise Time}$
and $RC > 100 \times \text{CKI Period}$

FIGURE 5. Power-Up Clear Circuit

COP411C

If the COP410C is bonded as a 20-pin package, it becomes the COP411C, illustrated in *Figure 2*, COP410C/411C Connection Diagrams. Note that the COP411C does not contain D2, D3, G3, or CKO. Use of this option, of course, precludes use of D2, D3, G3, and CKO options. All other options are available for the COP411C.

TABLE I. Enable Register Modes — Bits EN0 and EN3

EN0	EN3	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = clock If SKL = 0, SK = 0
0	1	Shift Register	Input to Shift Register	Serial out	If SKL = 1, SK = clock If SKL = 0, SK = 0
1	0	Binary Counter	Input to Counter	0	SK = SKL
1	1	Binary Counter	Input to Counter	1	SK = SKL

Functional Description (Continued)

HALT MODE

The COP410C/411C is a *fully static* circuit; therefore, the user may stop the system oscillator at any time to halt the chip. The chip also may be halted by the HALT instruction or by forcing CKO high when it is used as a HALT I/O port. Once in the HALT mode, the internal circuitry does not receive any clock signal, and is therefore frozen in the exact state it was in when halted. All information is retained until continuing. The HALT mode is the minimum power dissipation state.

The HALT mode has slight differences depending upon the type of oscillator used.

a. 1-pin oscillator—RC or external

The HALT mode may be entered into by either program control (HALT instruction) or by forcing CKO to a logic "1" state.

The circuit may be awakened by one of two different methods:

- 1) Continue function. By forcing CKO to a logic "0", the system clock is re-enabled and the circuit continues to operate from the point where it was stopped.
- 2) Restart. Forcing the $\overline{\text{RESET}}$ pin to a logic "0" will restart the chip regardless of HALT or CKO (see initialization).

b. 2-pin oscillator—crystal

The HALT mode may be entered into by program control (HALT instruction) which forces CKO to a logic "1" state. The circuit can be awakened only by the $\overline{\text{RESET}}$ function.

TL/DD/5015-7

Halt I/O Port

CKO Pin Options

In a crystal-controlled oscillator system, CKO is used as an output to the crystal network. CKO will be forced high during the execution of a HALT instruction, thus inhibiting the crystal network. If a 1-pin oscillator system is chosen (RC or external), CKO will be selected as HALT and is an I/O

flip-flop which is an indicator of the HALT status. An external signal can override this pin to start and stop the chip. By forcing a high level to CKO, the chip will stop as soon as CKI is high and the CKO output will go high to keep the chip stopped. By forcing a low level to CKO, the chip will continue and CKO output will go low.

All features associated with the CKO I/O pin are available with the 24-pin package only.

OSCILLATOR OPTIONS

There are three options available that define the use of CKI and CKO.

- a. Crystal-Controlled Oscillator. CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 16 (optionally by 8 or 4).
- b. External Oscillator. CKI is configured as LSTTL-compatible input accepting an external clock signal. The external frequency is divided by 16 (optionally by 8 or 4) to give the instruction cycle time. CKO is the HALT I/O port.
- c. RC-Controlled Oscillator. CKI is configured as a single pin RC-controlled Schmitt trigger oscillator. The instruction cycle time equals the oscillation frequency divided by 4. CKO is the HALT I/O port.

The RC oscillator is not recommended in systems that require accurate timing or low current. The RC oscillator draws more current than an external oscillator (typically an additional 100 μA at 5V). However, when the part halts, it stops with CKI high and the halt current is at the minimum.

TL/DD/5015-8

FIGURE 6. COP410C Oscillator

Crystal or Resonator

Crystal Value	Component Value				RC-Controlled Oscillator			
	R1	R2	C1 pF	C2 pF	R	C	Cycle Time	V _{CC}
32 kHz	220k	20M	30	5-36	15k	82 pF	4-9 μs	$\geq 4.5\text{V}$
455 kHz	5k	10M	80	40	30k	82 pF	8-16 μs	$\geq 4.5\text{V}$

COP410C/COP411C Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP410C/411C instruction set.

TABLE II. COP410C/411C Instruction Set Table Symbols

Symbol	Definition	Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS		INSTRUCTION OPERAND SYMBOLS	
A	4-bit Accumulator	d	4-bit Operand Field, 0-15 binary (RAM Digit Select)
B	6-bit RAM Address Register	r	2-bit Operand Field, 0-3 binary (RAM Register Select)
Br	Upper 2 bits of B (register address)	a	9-bit Operand Field, 0-511 binary (ROM Address)
Bd	Lower 4 bits of B (digit address)	y	4-bit Operand Field, 0-15 binary (Immediate Data)
C	1-bit Carry Register	RAM(s)	Contents of RAM location addressed by s
D	4-bit Data Output Port	ROM(t)	Contents of ROM location addressed by t
EN	4-bit Enable Register	OPERATIONAL SYMBOLS	
G	4-bit Register to latch data for G I/O Port	+	Plus
L	8-bit TRI-STATE I/O Port	-	Minus
M	4-bit contents of RAM Memory pointed to by B Register	→	Replaces
PC	9-bit ROM Address Register (program counter)	↔	Is exchanged with
Q	8-bit Register to latch data for L I/O Port	=	Is equal to
SA	9-bit Subroutine Save Register A	\bar{A}	The one's complement of A
SB	9-bit Subroutine Save Register B	⊕	Exclusive-OR
SIO	4-bit Shift Register and Counter	:	Range of values
SK	Logic-Controlled Clock Output

		3A	0011 1010			
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO

Note 1: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 2: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP410C/411C programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register). If SIO is selected as a shift register, an XAS instruction must be performed once every four instruction cycle times to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower eight bits of the ROM address register PC with the contents of ROM addressed by the 9-bit word, PC₈, A, M. PC₈ is not affected by this instruction.

Note: JID uses two instruction cycles if executed, one if skipped.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 9-bit word PC₈, A, M. LQID can be used for table look-up or code conversion such as BCD to 7-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB) and replaces the least significant eight bits of the PC as follows: A → PC_{7:4}, RAM(B) → PC_{3:0}, leaving PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SB → SA → PC), restoring the saved value of the PC to continue sequential program execution. Since LQID pushes SA → SB, the previous contents of SB are lost.

Note: LQID uses two instruction cycles if executed, one if skipped.

INSTRUCTION SET NOTES

- The first word of a COP410C/411C program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths take the same number of cycle times whether instructions are skipped or executed (except JID and LQID).
- The ROM is organized into eight pages of 64 words each. The program counter is a 9-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID, or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: A JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word in page 3 or 7 will access data in the next group of four pages.

POWER DISSIPATION

The lowest power drain is when the clock is stopped. As the frequency increases so does current. Current is also lower at lower operating voltages. Therefore, to minimize power consumption, the user should run at the lowest speed and voltage that his application will allow. The user should take care that all pins swing to full supply levels to ensure that outputs are not loaded down and that inputs are not at some intermediate level which may draw current. Any input with a slow rise or fall time will draw additional current. A crystal- or resonator-generated clock will draw additional current. An RC oscillator will draw even more current since the input is a slow rising signal.

If using an external squarewave oscillator, the following equation can be used to calculate the COP410C current drain.

$$I_c = I_q + (V \times 20 \times F_i) + (V \times 1280 \times F_i/D_v)$$

where I_c = chip current drain in microamps

I_q = quiescent leakage current (from curve)

F_i = CKI frequency in megahertz

V = chip V_{CC} in volts

D_v = divide by option selected

For example, at 5V V_{CC} and 400 kHz (divide by 4),

$$I_c = 10 + (5 \times 20 \times 0.4) + (5 \times 1280 \times 0.4/4)$$

$$I_c = 10 + 40 + 640 = 690 \mu A$$

I/O OPTIONS

COP410C/411C outputs have the following optional configurations, illustrated in *Figure 7*:

- Standard. A CMOS push-pull buffer with an N-channel device to ground in conjunction with a P-channel device to V_{CC} , compatible with CMOS and LSTTL.
- Low Current. This is the same configuration as (a) above except that the sourcing current is much less.
- Open Drain. An N-channel device to ground only, allowing external pull-up as required by the user's application.
- Standard TRI-STATE L Output. A CMOS output buffer similar to (a) which may be disabled by program control.
- Low-Current TRI-STATE L Output. This is the same as (d) above except that the sourcing current is much less.
- Open-Drain TRI-STATE L Output. This has the N-channel device to ground only.

The SI and RESET inputs are Hi-Z inputs (*Figure 7g*).

When using either the G or L I/O ports as inputs, a pull-up device is necessary. This can be an external device or the following alternative is available: Select the low-current output option. Now, by setting the output registers to a logic "1" level, the P-channel devices will act as the pull-up load. Note that when using the L ports in this fashion, the Q registers must be set to a logic "1" level and the L drivers *must be enabled* by an LEI instruction.

Functional Description (Continued)

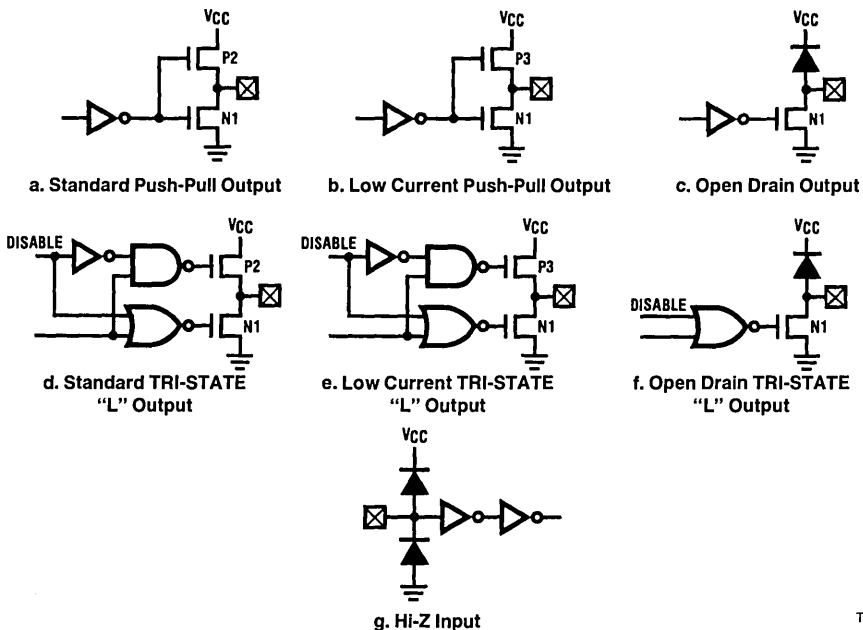

FIGURE 7. I/O Configurations

TL/DD/5015-9

Typical Performance Characteristics

FIGURE 8

TL/DD/5015-10

All output drivers uses one or more of three common devices numbered 1 to 3. Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 8* for each of these devices to allow the designer to effectively use these I/O configurations.

Option List

The COP410C/411C mask-programmable options are assigned numbers which correspond with the COP410C pins. The following is a list of COP410C options. When specifying a COP411 chip, options 20, 21, and 22 must be set to 0. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

- Option 1: 0 = Ground Pin. No options available.
- Option 2: CKO I/O Port. (Determined by Option 3.)
= 0: No option.
(a. is crystal oscillator output for two pin oscillator.
b. is HALT I/O for one pin oscillator.)
- Option 3: CKI Input.
= 0: Crystal-controlled oscillator input ($\div 4$).
= 1: Single-pin RC-controlled oscillator ($\div 4$).
= 2: External oscillator input ($\div 4$).
= 3: Crystal oscillator input ($\div 8$).
= 4: External oscillator input ($\div 8$).
= 5: Crystal oscillator input ($\div 16$).
= 6: External oscillator input ($\div 16$).
- Option 4: RESET Input = 1: Hi-Z input. No option available.
- Option 5: L₇ Driver
= 0: Standard TRI-STATE push-pull output.
= 1: Low-current TRI-STATE push-pull output.
= 2: Open-drain TRI-STATE output.

- Option 6: L₆ Driver. (Same as Option 5.)
- Option 7: L₅ Driver. (Same as Option 5.)
- Option 8: L₄ Driver. (Same as Option 5.)
- Option 9: V_{CC} Pin = 0 no option.
- Option 10: L₃ Driver. (Same as Option 5.)
- Option 11: L₂ Driver. (Same as Option 5.)
- Option 12: L₁ Driver. (Same as Option 5.)
- Option 13: L₀ Driver. (Same as Option 5.)
- Option 14: SI Input.
No option available.
= 1: Hi-Z input.
- Option 15: SO Output.
= 0: Standard push-pull output.
= 1: Low-current push-pull output.
= 2: Open-drain output.
- Option 16: SK Driver. (Same as Option 15.)
- Option 17: G₀ I/O Port. (Same as Option 15.)
- Option 18: G₁ I/O Port. (Same as Option 15.)
- Option 19: G₂ I/O Port. (Same as Option 15.)
- Option 20: G₃ I/O Port. (Same as Option 15.)
- Option 21: D₃ Output. (Same as Option 15.)
- Option 22: D₂ Output. (Same as Option 15.)
- Option 23: D₁ Output. (Same as Option 15.)
- Option 24: D₀ Output. (Same as Option 15.)
- Option 25: Internal Initialization Logic.
= 0: Normal operation.
= 1: No internal initialization logic.
- Option 26: No option available.
- Option 27: COP Bonding
= 0: COP410C (24-pin device).
= 1: COP411C (20-pin device). See note.
= 2: COP410C and COP411C. See note.

Note: If opt. #27 = 1 or 2 then opt #20 must = 0.

Option Table

Please fill out a photocopy of the option table and send it along with your EPROM.

COP410L/COP411L/COP310L/COP311L Single-Chip N-Channel Microcontrollers

General Description

The COP410L and COP411L Single-Chip N-Channel Microcontrollers are members of the COPSTM family, fabricated using N-channel, silicon gate MOS technology. These Controller Oriented Processors are complete microcomputers containing all system timing, internal logic, ROM, RAM and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP411L is identical to the COP410L, but with 16 I/O lines instead of 19. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Controller Oriented Processor at a low end-product cost.

The COP310L and COP311L are exact functional equivalents but extended temperature versions of COP410L and COP411L respectively.

The COP401L should be used for exact emulation.

Features

- Low cost
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- 19 I/O lines (COP410L)
- Two-level subroutine stack
- 16 μ s instruction time
- Single supply operation (4.5V–6.3V)
- Low current drain (6 mA max)
- Internal binary counter register with MICROWIRE™ serial I/O capability
- General purpose and TRI-STATE® outputs
- LSTTL/CMOS compatible in and out
- Direct drive of LED digit and segment lines
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device
— COP310L/COP311L (–40°C to +85°C)

COP410L/COP411L

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at Any Pin Relative to GND	-0.5V to +10V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	-65°C to +150°C
Lead Temperature (Soldering, 10 seconds)	300°C

Power Dissipation
COP410L

0.75W at 25°C
0.4W at 70°C

COP411L

0.65W at 25°C
0.3W at 70°C

Total Source Current

120 mA

Total Sink Current

100 mA

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics 0°C ≤ T_A ≤ +70°C, 4.5V ≤ V_{CC} ≤ 6.3V unless otherwise noted

Parameter	Conditions	Min	Max	Units
Standard Operating Voltage (V _{CC})		4.5	6.3	V
Power Supply Ripple (Notes 1, 4)	Peak to Peak		0.5	V

FIGURE 3a. Synchronization Timing

TL/DD/6919-5

Functional Description

A block diagram of the COP410L is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2V). When a bit is reset, it is a logic "0" (less than 0.8V).

All functional references to the COP410L/COP411L also apply to the COP310L/COP311L.

PROGRAM MEMORY

Program Memory consists of a 512-byte ROM. As can be seen by an examination of the COP410L/411L instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words each.

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by the 9-bit subroutine save registers, SA and SB, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 128-bit RAM, organized as 4 data registers of 8 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper 2 bits (Br) select 1 of 4 data registers and lower 3 bits of the 4-bit Bd select 1 of 8 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it

may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3,15 instruction. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs. The most significant bit of Bd is not used to select a RAM digit. Hence each physical digit of RAM may be selected by two different values of Bd as shown in *Figure 4* below. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 and 15, but NOT between 7 and 8 (see Table III).

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

TL/DD/6919-6

Functional Description (Continued)

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the B_d portion of the B register, to load 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions of the COP410L/411L, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below.)

The G register contents are outputs to 4 general-purpose bidirectional I/O ports.

The Q register is an internal, latched, 8-bit register, used to hold data loaded from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M. L I/O ports can be directly connected to the segments of a multiplexed LED display (using the LED Direct Drive output configuration option) with Q data being outputted to the Sa–Sg and decimal point segments of the display.

The SIO register functions as a 4-bit serial-in serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers.

The XAS instruction copies C into the SKL Latch. In the counter mode, SK is the output of SKL in the shift register mode, SK outputs SKL ANDed with internal instruction cycle clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN₃–EN₀).

1. The least significant bit of the enable register, EN₀, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, *decrementing* its value by one upon

each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.

2. EN₁ is not used. It has no effect on COP410L/COP411L operation.
3. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN₂ disables the L drivers, placing the L I/O ports in a high-impedance input state.
4. EN₃, in conjunction with EN₀, affects the SO output. With EN₀ set (binary counter option selected) SO will output the value loaded into EN₃. With EN₀ reset (serial shift register option selected), setting EN₃ enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN₃ with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0." Table I provides a summary of the modes associated with EN₃ and EN₀.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below (Figure 5). The RESET pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC}. Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

FIGURE 5. Power-Up Clear Circuit

TABLE I. Enable Register Modes—Bits EN₃ and EN₀

EN ₃	EN ₀	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = Clock If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = Clock If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

Functional Description (Continued)

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

TL/DD/6919-8

Ceramic Resonator Oscillator

Resonator Value	Components Values			
	R1 (Ω)	R2 (Ω)	C1 (pF)	C2 (pF)
455 kHz	4.7k	1M	220	220

RC Controlled Oscillator

51	100	19 \pm 15%
82	56	19 \pm 13%

Note: 200 k Ω \geq R \geq 25 k Ω . 360 pF \geq C \geq 50 pF. Does not include tolerances.

FIGURE 6. COP410L/411L Oscillator

OSCILLATOR

There are three basic clock oscillator configurations available as shown by Figure 6.

- Resonator Controlled Oscillator.** CKI and CKO are connected to an external ceramic resonator. The instruction cycle frequency equals the resonator frequency divided by 8. This is not available in the COP411L.
- External Oscillator.** CKI is an external clock input signal. The external frequency is divided by 4 to give the instruction frequency time. CKO is now available to be used as the RAM power supply (V_R), or no connection.

Note: No CKO on COP411L.

- RC Controlled Oscillator.** CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is available as the RAM power supply (V_R) or no connection.

CKO PIN OPTIONS

In a resonator controlled oscillator system, CKO is used as an output to the resonator network. As an option, CKO can be a RAM power supply pin (V_R), allowing its connection to a standby/backup power supply to maintain the integrity of RAM data with minimum power drain when the main supply is inoperative or shut down to conserve power. Using no connection option is appropriate in applications where the COP410L system timing configuration does not require use of the CKO pin.

RAM KEEP-ALIVE OPTION

Selecting CKO as the RAM power supply (V_R) allows the user to shut off the chip power supply (V_{CC}) and maintain data in the RAM. To insure that RAM data integrity is maintained, the following conditions must be met:

- \overline{RESET} must go low before V_{CC} goes below spec during power-off; V_{CC} must be within spec before \overline{RESET} goes high on power-up.
- During normal operation, V_R must be within the operating range of the chip with $(V_{CC} - 1) \leq V_R \leq V_{CC}$.
- V_R must be $\geq 3.3V$ with V_{CC} off.

I/O OPTIONS

COP410L/411L inputs and outputs have the following optional configurations, illustrated in Figure 7:

- Standard**—an enhancement-mode device to ground in conjunction with a depletion-mode device to V_{CC} , compatible with LSTTL and CMOS input requirements. Available on SO, SK, and all D and G outputs.
 - Open-Drain**—an enhancement-mode device to ground only, allowing external pull-up as required by the user's application. Available on SO, SK, and all D and G outputs.
 - Push-Pull**—an enhancement-mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads. Available on SO and SK outputs only.
 - Standard L**—same as a., but may be disabled. Available on L outputs only.
 - Open Drain L**—same as b., but may be disabled. Available on L outputs only.
 - LED Direct Drive**—an enhancement mode device to ground and to V_{CC} , meeting the typical current sourcing requirements of the segments of an LED display. The sourcing device is clamped to limit current flow. These devices may be turned off under program control (see Functional Description, EN Register), placing the outputs in a high-impedance state to provide required LED segment blanking for a multiplexed display. Available on L outputs only.
- Note: Series current limiting resistors must be used if LEDs are driven directly and higher operating voltage option is selected.
- TRI-STATE Push-Pull**—an enhancement-mode device to ground and V_{CC} . These outputs are TRI-STATE outputs, allowing for connection of these outputs to a data bus shared by other bus drivers. Available on L outputs only.

Functional Description (Continued)

h. An on-chip depletion load device to V_{CC} .

i. A Hi-Z input which must be driven to a "1" or "0" by external components.

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of six devices (numbered 1–6, respectively). Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 8* for each of these devices to allow the designer to effectively use these I/O configurations in designing a COP410L/411L system.

The SO, SK outputs can be configured as shown in a., b., or c. The D and G outputs can be configured as shown in a. or b. Note that when inputting data to the G ports, the G outputs should be set to "1". The L outputs can be configured as in d., e., f., or g.

An important point to remember if using configuration d. or f. with the L drivers is that even when the L drivers are disabled, the depletion load device will source a small amount of current. (See *Figure 8*, device 2.) However, when the L port is used as input, the disabled depletion device CANNOT be relied on to source sufficient current to pull an input to a logic "1".

COP411L

If the COP410L is bonded as a 20-pin device, it becomes the COP411L, illustrated in *Figure 2*, COP410L/411L Connection Diagrams. Note that the COP411L does not contain D2, D3, G3, or CKO. Use of this option of course precludes use of D2, D3, G3, and CKO options. All other options are available for the COP411L.

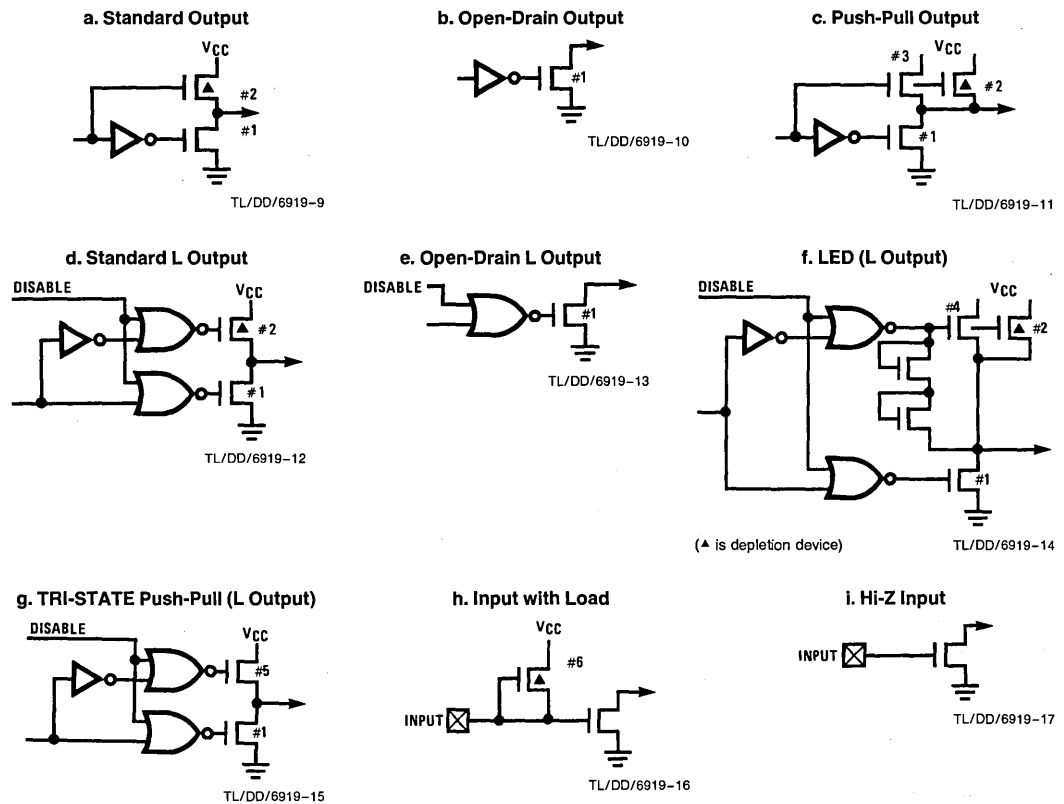

FIGURE 7. Input and Output Configurations

L-Bus Considerations

False states may be generated on L₀–L₇ during the execution of the CAMQ instruction. The L-ports should not be used as clocks for edge sensitive devices such as flip-flops, counters, shift registers, etc. the following short program that illustrates this situation.

START:

```
CLRA           ;ENABLE THE Q
LEI 4         ;REGISTER TO L LINES
LBI TEST
STII 3
AISC 12
```

LOOP:

```
LBI TEST ;LOAD Q WITH X'C3
CAMQ
JP LOOP
```

In this program the internal Q register is enabled onto the L lines and a steady bit pattern of logic highs is output on L₀, L₁, L₆, L₇, and logic lows on L₂–L₅ via the two-byte CAMQ instruction. Timing constraints on the device are such that the Q register may be temporarily loaded with the second byte of the CAMQ opcode (X'3C) prior to receiving the valid data pattern. If this occurs, the opcode will ripple onto the L lines and cause negative-going glitches on L₀, L₁, L₆, L₇, and positive glitches on L₂–L₅. Glitch durations are under 2 μ s, although the exact value may vary due to data patterns, processing parameters, and L line loading. These false states are peculiar only to the CAMQ instruction and the L lines.

Typical Performance Characteristics

COP410L/411L Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP410L/411L instruction set.

TABLE II. COP410L/411L Instruction Set Table Symbols

Symbol	Definition	Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS		INSTRUCTION OPERAND SYMBOLS	
A	4-bit Accumulator	d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
B	6-bit RAM Address Register	r	2-bit Operand Field, 0–3 binary (RAM Register Select)
Br	Upper 2 bits of B (register address)	a	9-bit Operand Field, 0–511 binary (ROM Address)
Bd	Lower 4 bits of B (digit address)	y	4-bit Operand Field, 0–15 binary (Immediate Data)
C	1-bit Carry Register	RAM(s)	Contents of RAM location addressed by s
D	4-bit Data Output Port	ROM(t)	Contents of ROM location addressed by t
EN	4-bit Enable Register		
G	4-bit Register to latch data for G I/O Port		
L	8-bit TRI-STATE I/O Port		
M	4-bit contents of RAM Memory pointed to by B Register		
PC	9-bit ROM Address Register (program counter)		
Q	8-bit Register to latch data for L I/O Port		
SA	9-bit Subroutine Save Register A		
SB	9-bit Subroutine Save Register B		
SIO	4-bit Shift Register and Counter		
SK	Logic-Controlled Clock Output		
		OPERATIONAL SYMBOLS	
		+	Plus
		–	Minus
		→	Replaces
		↔	Is exchanged with
		=	Is equal to
		\bar{A}	The one's complement of A
		⊕	Exclusive-OR
		:	Range of values

INPUT/OUTPUT INSTRUCTIONS						
ING		33 2A	0011 0011 0010 1010	G → A	None	Input G Ports to A
INL		33 2E	0011 0011 0010 1110	L _{7:4} → RAM(B) L _{3:0} → A	None	Input L Ports to RAM, A
OBD		33 3E	0011 0011 0011 1110	Bd → D	None	Output Bd to D Outputs
OMG		33 3A	0011 0011 0011 1010	RAM(B) → G	None	Output RAM to G Ports
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 2)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: For additional information on the operation of the XAS, JID, and LQID instructions, see below.

Note 3: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 4: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 5: The machine code for the lower 4 bits of the LBI instruction equals the binary value of the "d" data *minus 1*, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 6: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP410L/411L programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the contents of ROM addressed by the 9-bit word, PC₈, A, M. PC₈ is not affected by this instruction.

Note that JID requires 2 instruction cycles to execute.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 9-bit word PC₈, A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB) and replaces the least significant 8 bits of PC as follows: A → PC_{7,4}, RAM(B) → PC_{3,0}, leaving PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SA → SB, the previous contents of SB are lost. Also, when LQID pops the stack, the previously pushed contents of SA are left in SB. The net result is that the contents of SA are placed in SB (SA → SB). Note that LQID takes two instruction cycle times to execute.

INSTRUCTION SET NOTES

- The first word of a COP410L/411L program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths except JID and LQID take the same number of cycle times whether instructions are skipped or executed. JID and LQID instructions take 2 cycles if executed and 1 cycle if skipped.
- The ROM is organized into 8 pages of 64 words each. The Program Counter is a 9-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3 or 7 will access data in the next group of 4 pages.

Option List

The COP410L/411L mask-programmable options are assigned numbers which correspond with the COP410L pins.

The following is a list of COP410L options. The LED Direct Drive option on the L Lines cannot be used if higher V_{CC} option is selected. When specifying a COP411L chip, Option 2 must be set to 3, Options 20, 21, and 22 to 0. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

Option 1 = 0: Ground Pin — no options available

Option 2: CKO Output (no option available for COP411L)

- = 0: Clock output to ceramic resonator
- = 1: Pin is RAM power supply (V_R) input
- = 3: No connection

Option 3: CKI Input

- = 0: Oscillator input divided by 8 (500 kHz max)
- = 1: Single-pin RC controlled oscillator divided by 4
- = 2: External Schmitt trigger level clock divided by 4

Option 4: RESET Input

- = 0: Load device to V_{CC}
- = 1: Hi-Z input

Option 5: L₇ Driver

- = 0: Standard output
- = 1: Open-drain output
- = 2: High current LED direct segment drive output
- = 3: High current TRI-STATE push-pull output
- = 4: Low-current LED direct segment drive output
- = 5: Low-current TRI-STATE push-pull output

Option 6: L₈ Driver

same as Option 5

Option 7: L₅ Driver

same as Option 5

Option 8: L₄ Driver

same as Option 5

Option 9: Operating voltage

- | | | |
|------|----------------|----------------|
| | COP41XL | COP31XL |
| = 0: | +4.5V to +6.3V | +4.5V to +5.5V |

Option 10: L₃ Driver

same as Option 5

Option 11: L₂ Driver

same as Option 5

Option 12: L₁ Driver

same as Option 5

Option 13: L₀ Driver

same as Option 5

Option 14: SI Input

- = 0: load device to V_{CC}
- = 1: Hi-Z input

Option 15: SO Driver

- = 0: Standard Output
- = 1: Open-drain output
- = 2: Push-pull output

Option 16: SK Driver

same as Option 15

Option List (Continued)

- Option 17: G₀ I/O Port
 = 0: Standard output
 = 1: Open-drain output
- Option 18: G₁ I/O Port
 same as Option 17
- Option 19: G₂ I/O Port
 same as Option 17
- Option 20: G₃ I/O Port (no option available for COP411L)
 same as Option 17
- Option 21: D₃ Output (no option available for COP411L)
 = 0: Very-high sink current standard output
 = 1: Very-high sink current open-drain output
 = 2: High sink current standard output
 = 3: High sink current open-drain output
 = 4: Standard LSTTL output (fanout = 1)
 = 5: Open-drain LSTTL output (fanout = 1)
- Option 22: D₂ Output (no option available for COP411L)
 same as Option 21
- Option 23: D₁ Output
 same as Option 21
- Option 24: D₀ Output
 same as Option 21

- Option 25: L Input Levels
 = 0: Standard TTL input levels ("0" = 0.8V, "1" = 2.0V)
 = 1: Higher voltage input levels ("0" = 1.2V, "1" = 3.6V)
- Option 26: G Input Levels
 same as Option 25
- Option 27: SI Input Levels
 same as Option 25
- Option 28: COP Bonding
 = 0: COP410L (24-pin device)
 = 1: COP411L (20-pin device)
 = 2: Both 24- and 20-pin versions

TEST MODE (NON-STANDARD OPERATION)

The SO output has been configured to provide for standard test procedures for the custom-programmed COP410L. With SO forced to logic "1", two test modes are provided, depending upon the value of SI:

- a. RAM and Internal Logic Test Mode (SI = 1)
- b. ROM Test Mode (SI = 0)

These special test modes should not be employed by the user; they are intended for manufacturing test only.

Option Table

The following option information is to be sent to National along with the EPROM.

	Option Data	
OPTION 1	VALUE = <u>0</u>	IS: GROUND PIN

COP413L/COP313L Single Chip Microcontrollers

General Description

The COP413L and COP313L Single-Chip N-Channel Microcontrollers are members of the COPSM family, fabricated using N-channel, silicon gate MOS technology. These Control Oriented Processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, 15 I/O lines with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Control Oriented Processor at a very low end-product cost.

The COP313L is an exact functional equivalent but extended temperature version of the COP413L.

The COP401L-R13 and COP410L-X13 should be used for exact emulation.

Features

- Low cost
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- 15 I/O lines
- Two-Level subroutine stack
- 16 μ s instruction time
- Single supply operation (4.5V–6.3V)
- Low current drain (6 mA max.)
- Internal binary counter register with MICROWIRESM serial I/O capability
- General purpose outputs
- High noise immunity inputs ($V_{IL} = 1.2V$, $V_{IH} = 3.6V$)
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device COP313L ($-40^{\circ}C$ to $+85^{\circ}C$)

FIGURE 3. Input/Output Timing Diagrams (Ceramic Resonator Divide-by-8 Mode)

TL/DD/8371-3

Functional Description

A block diagram of the COP413L is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2V). When a bit is reset, it is a logic "0" (less than 0.8V).

All functional references to the COP413L also apply to the COP313L.

PROGRAM MEMORY

Program Memory consists of a 512-byte ROM. As can be seen by an examination of the COP413L instruction set, these words may be program instructions, program data, or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words each.

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by the 9-bit subroutine save registers, SA and SB, providing a last-in, first out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 128-bit RAM, organized as 4 data registers of 8 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper 2 bits (Br) select 1 of 4 data registers and lower 3 bits of the 4-bit Bd select 1 of 8 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3, 15 instruction.

The most significant bit of Bd is not used to select a RAM digit. Hence each physical digit of RAM may be selected by two different values of Bd as shown in *Figure 4* below. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 and 15, but NOT between 7 and 8 (see Table III).

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Bd portion of the B register, to load 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions of the COP413L, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below.)

The G register contents are outputs to 4 general purpose bidirectional I/O ports.

TL/DD/8371-4

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

The Q register is an internal, latched, 8-bit register, used to hold data loaded from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M.

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers.

The XAS instruction copies C into the SKL Latch. In the counter mode, SK is the output of SKL in the shift register mode, SK outputs SKL ANDed with internal instruction cycle clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN₃-EN₀).

1. The least significant bit of the enable register, EN₀ selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, decrementing its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting with each instruction cycle time. The data present at SO goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.

2. EN₁ is not used. It has no effect on COP413L operation.

Functional Description (Continued)

TABLE I. Enable Register Modes - Bits EN₃ and EN₀

EN ₃	EN ₀	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = Clock If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = Clock If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

3. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN₂ disables the L drivers, placing the L I/O ports in a high impedance input state.

4. EN₃, in conjunction with EN₀, affects the SO output. With EN₀ set (binary counter option selected) SO will output the value loaded into EN₃. With EN₀ reset (serial shift register option selected), setting EN₃ enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN₃ with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0". Table I provides a summary of the modes associated with EN₃ and EN₀.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below (Figure 5). The RESET pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC}. Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

FIGURE 5. Power-Up Clear Circuit

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

OSCILLATOR

There are two basic clock oscillator configurations available as shown by Figure 6.

- Resonator Controlled Oscillator. CKI and CKO are connected to an external ceramic resonator. The instruction cycle frequency equals the resonator frequency divided by 8.
- RC Controlled Oscillator. CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO becomes no connection.

FIGURE 6. COP413L Oscillator

Ceramic Resonator Oscillator

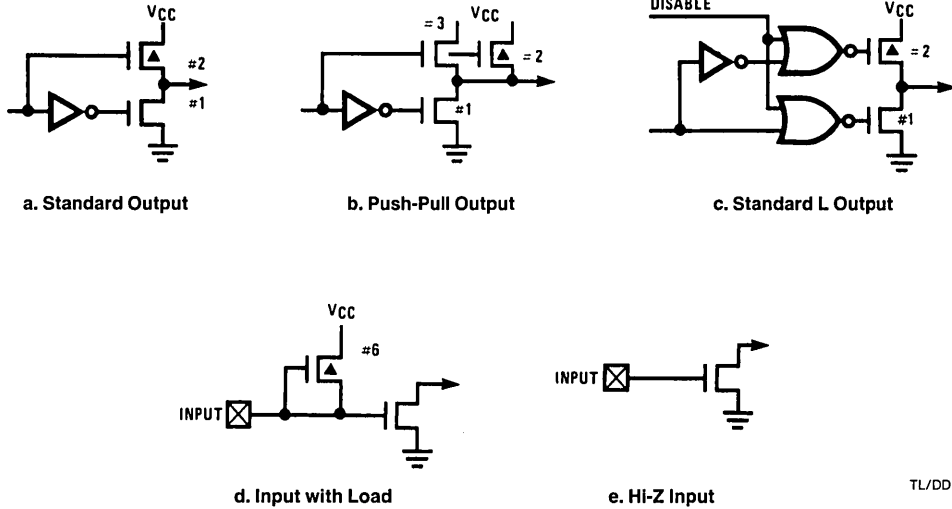

Resonator Value	Component Values			
	R1 (Ω)	R2 (Ω)	C1 (pF)	C2 (pF)
455 kHz	4.7k	1M	220	220

RC Controlled Oscillator

R (k Ω)	C (pF)	Instruction Cycle Time (in μ s)
51	100	19 \pm 15%
82	56	19 \pm 13%

Note: 200 k Ω \geq R \geq 25 k Ω
220 pF \geq C \geq 50 pF

Functional Description (Continued)

FIGURE 7. Input and Output Configurations

I/O CONFIGURATIONS

COP413L inputs and outputs have the following configurations, illustrated in *Figure 7*:

- a. G0–G3—an enhancement mode device to ground in conjunction with a depletion-mode device to V_{CC} .
- b. SO, SK—an enhancement mode device to ground in conjunction with a depletion-mode device paralleled by an

enhancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads.

- c. L0–L7—same as a., but may be disabled.
- d. SI has on-chip depletion load device to V_{CC} .
- e. $\overline{\text{RESET}}$ has a Hi-Z input which must be driven to a “1” or “0” by external components.

COP413L Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table. Table III provides the mnemonic, oper-

and, machine code data flow, skip conditions and description associated with each instruction in the COP413L instruction set.

TABLE II. COP413L Instruction Set Table Symbols

Symbol	Definition
Internal Architecture Symbols	
A	4-bit Accumulator
B	6-bit RAM Address Register
Br	Upper 2 bits of B (register address)
Bd	Lower 4 bits of B (digit address)
C	1-bit Carry Register
EN	4-bit Enable Register
G	4-bit Register to latch data for G I/O Port
L	8-bit TRI-STATE® I/O Port
M	4-bit contents of RAM Memory pointed to by B Register
PC	9-bit ROM Address Register (program counter)
Q	8-bit Register to latch data for L I/O Port
SA	9-bit Subroutine Save Register A
SB	9-bit Subroutine Save Register B
SIO	4-bit Shift Register and Counter
SK	Logic Controlled Clock Output
Instruction Operand Symbols	
d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
r	2-bit Operand Field, 0–3 binary (RAM Register Select)
a	9-bit Operand Field, 0–511 binary (ROM Address)
y	4-bit Operand Field, 0–15 binary (Immediate Data)
RAM(s)	Contents of RAM location addressed by s
ROM(t)	Contents of ROM location addressed by t
Operational Symbols	
+	Plus
–	Minus
→	Replaces
↔	Is exchanged with
=	Is equal to
\bar{A}	The one's complement of A
⊕	Exclusive-OR
:	Range of values

COP413L Instruction Set (Continued)

TABLE III. COP413L Instruction Set (Continued)

Mnemonic	Operand	Machine		Data Flow	Skip Conditions	Description
		Hex Code	Language Code (Binary)			
INPUT/OUTPUT INSTRUCTIONS						
ING		33	0011 0011	G → A	None	Input G Ports to A
		2A	0010 1010			
INL		33	0011 0011	L _{7:4} → RAM(B) L _{3:0} → A	None	Input L Ports to RAM, A
		2E	0010 1110			
OMG		33	0011 0011	RAM(B) → G	None	Output RAM to G Ports
		3A	0011 1010			
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 2)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined) Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: For additional information on the operation of the XAS, JID, and LQID instructions, see below.

Note 3: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 4: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 5: The machine code for the lower 4 bits of the LBI instruction equals the binary value of the "d" data *minus 1* e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 6: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP413L programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the *contents* of ROM addressed by the 9-bit word, PC₈, A, M. PC₈ is not affected by this instruction.

Note that JID requires 2 instruction cycles to execute.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 9-bit word PC₈, A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB) and replaces the least significant 8 bits of PC as follows: A → PC_{7:4}, RAM (B)

→ PC_{3:0}, leaving PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SA → SB, the previous contents of SB are lost. Also, when LQID pops the stack, the previously pushed contents of SA are left in SB. The net result is that the contents of SA are placed in SB (SA → SB). Note that LQID takes two instruction cycle times to execute.

INSTRUCTION SET NOTES

- The first word of a COP413L program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths except JID and LQID take the same number of cycle times whether instructions are skipped or executed. JID and LQID instructions take 2 cycles if executed and 1 cycle if skipped.
- The ROM is organized into 8 pages of 64 words each. The Program Counter is a 9-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3 or will access data in the next group of 4 pages.

Description of Selected Instructions (Continued)

TEST MODE (NON-STANDARD OPERATION)

The SO output has been configured to provide for standard test procedures for the custom-programmable COP413L. With SO forced to logic "1", two test modes are provided, depending upon the value of SI:

- a. RAM and internal Logic Test Mode (SI = 1)
- b. ROM Test Mode (SI = 0)

These special test modes should not be employed by the user; they are intended for manufacturing test only.

Option List

The option selected must be sent in with the EPROM of ROM Code for a Mask order of 413L. Make xerox copy of the table, select the appropriate option, and send it in with the EPROM.

COP 413L/COP 313L

Option 1: Oscillator Selection

= 0 Ceramic Resonator or external input frequency divided by 8. CKO is oscillator output.

= 1 Single pin RC controlled oscillator divided by 4. CKO is no connection.

NOTE:

The following option information is to be sent to National along with the EPROM

Option 1: Value = _____ is: Oscillator Selection

COP413C/COP413CH/COP313C/COP313CH

Single-Chip CMOS Microcontrollers

General Description

The COP413C, COP413CH, COP313C, and COP313CH fully static, single-chip CMOS microcontrollers are members of the COPSTM family, fabricated using double-poly, silicongate CMOS technology. These controller-oriented processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, with an instruction set, internal architecture, and I/O scheme designed to facilitate keyboard input, display output, and BCD data manipulation. The COP413CH is identical to the COP413C except for operating voltage and frequency. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide a customized controller-oriented processor at a low end-product cost.

The COP313C/COP313CH is the extended temperature range version of the COP413C/COP413CH.

For emulation use the ROMless COP404C.

Features

- Lowest power dissipation (40 μ W typical)
- Low cost
- Power-saving HALT Mode
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- 15 I/O lines
- Two-level subroutine stack
- DC to 4 μ s instruction time
- Single supply operation (3V to 5.5V)
- General purpose and TRI-STATE® outputs
- Internal binary counter with MICROWIRE™ compatible serial I/O
- Software/hardware compatible with other members of the COP400 family
- Extended temperature (-40°C to +85°C) devices available

Development Support

The MOLE (Microcontroller On Line Emulator) is a low cost development system and real time emulator for COPS' products. They also include TMP, 8050 and the new 16 bit HPC microcontroller family. The MOLE provides effective support for the development of both software and hardware in the user's application.

The purpose of the MOLE is to provide a tool to write and assemble code, emulate code for the target microcontroller and assist in debugging of the system.

The MOLE can be connected to various hosts, IBM PC, STARPLEX™, Kaypro, Apple and Intel systems, via RS-232 port. This link facilitates the up loading/down loading of code, supports host assembly and mass storage.

The MOLE consists of three parts; brain, personality and optional host software.

The brain board is the computing engine of the system. It is a self-contained computer with its own firmware which provides for all system operation, emulation control, communication, from programming and diagnostic operation. It has three serial ports which can be connected to a terminal, host system, printer, modem or to other MOLE's in a multi-MOLE environment.

The personality board contains the necessary hardware and firmware needed to emulate the target microcontroller. The emulation cable which replaces the target controller attaches to this board. The software contains a cross assembler and a communications program for up loading and down loading code from the MOLE.

MOLE-COPS-PB1	COPS Personality Board
MOLE-XXX-YYY	Optional Software

Where XXX = COPS

YYY = Host System, IBM, Apple,
KAY (Kaypro), CP/M

Functional Description

To ease reading of this description, only COP413C is referenced; however, all such references apply equally to COP413CH, COP313C, and COP313CH.

A block diagram of the COP413C is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1"; when a bit is reset, it is a logic "0".

PROGRAM MEMORY

Program memory consists of a 512-byte ROM. As can be seen by an examination of the COP413C instruction set, these words may be program instructions, program data, or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID, and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words (bytes) each.

ROM ADDRESSING

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by two 9-bit subroutine save registers, SA and SB.

ROM instruction words are fetched, decoded, and executed by the instruction decode, control and skip logic circuitry.

DATA MEMORY

Data Memory consists of a 128-bit RAM, organized as four data registers of 8×4 -bit digits. RAM addressing is implemented by a 6-bit B register whose upper two bits (Br) selects one of four data registers and lower three bits of the 4-bit Bd select one of eight 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) are usually loaded into or from, or exchanged with, the A register (accumulator), they may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3, 15 instruction.

The most significant bit of Bd is not used to select a RAM digit. Hence, each physical digit of RAM may be selected by two different values of Bd as shown in *Figure 4*. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 to 15, but *not* between 7 and 8 (see Table III).

INTERNAL LOGIC

The internal logic of the COP413C is designed to ensure fully static operation of the device.

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Bd portion of the B register, to load four bits of the 8-bit Q latch data and to perform data exchanges with the SIO register.

The 4-bit adder performs the arithmetic and logic functions of the COP413C, storing its results in A. It also outputs the carry information to a 1-bit carry register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description below.)

The G register contents are outputs to four general purpose bidirectional I/O ports.

The Q register is an internal, latched, 8-bit register, used to hold data loaded from RAM and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The eight L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and RAM.

TL/DD/8537-4

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

Functional Description (Continued)

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter, depending upon the contents of the EN register. (See EN register description below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. With SIO functioning as a serial-in/serial-out shift register and SK as a sync clock, the COP413C is MICROWIRE compatible.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK is a sync clock, inhibited when SKL is a logic "0".

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN3-EN0).

1. The least significant bit of the enable register, EN0, selects the SIO register as either a 4-bit shift register or as a 4-bit binary counter. With EN0 set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN3. With EN0 reset, SIO is a serial shift register, shifting left each instruction cycle time. The data present at SI is shifted into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each instruction cycle time. (See 4, below.) The SK output becomes a logic-controlled clock.
2. EN 1 is not used, it has no effect on the COP413C.
3. With EN2 set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN2 disables the L drivers, placing the L I/O ports in a high impedance input state.
4. EN3, in conjunction with EN0, affects the SO output. With EN0 set (binary counter option selected), SO will output the value loaded into EN3. With EN0 reset (serial shift

register option selected), setting EN3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN3 with the serial shift register option selected, disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0".

INITIALIZATION

The external RC network shown in *Figure 5* must be connected to the RESET pin. The RESET pin is configured as a Schmitt trigger input. If not used, it should be connected to V_{CC}. Initialization will occur whenever a logic "0" is applied to the RESET input, providing it stays low for at least three instruction cycle times.

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. Data memory (RAM) is not cleared upon initialization. The first instruction at address 0 must be a CLRA (clear A register).

$$RC > 5 \times \text{Power Supply Rise Time} \\ \text{and } RC > 100 \times \text{CKI Period}$$

TL/DD/8537-8

1	1	Binary Counter	Input to Counter	1	SK = SKL

Functional Description (Continued)

HALT MODE

The COP413C is a *fully static* circuit; therefore, the user may stop the system oscillator at any time to halt the chip. The chip may be halted by the HALT instruction. Once in the HALT mode, the internal circuitry does not receive any clock signal, and is therefore frozen in the exact state it was in when halted. All information is retained until continuing. The HALT mode is the minimum power dissipation state.

The HALT mode may be entered into by program control (HALT instruction) which forces CKO to a logic "1" state. The circuit can be awakened only by the RESET function.

POWER DISSIPATION

The lowest power drain is when the clock is stopped. As the frequency increases so does current. Current is also lower at lower operating voltages. Therefore, to minimize power consumption, the user should run at the lowest speed and voltage that his application will allow. The user should take care that all pins swing to full supply levels to ensure that outputs are not loaded down and that inputs are not at some intermediate level which may draw current. Any input with a slow rise or fall time will draw additional current. A crystal- or resonator-generated clock will draw more than a square-wave input. An RC oscillator will draw even more current since the input is a slow rising signal.

If using an external squarewave oscillator, the following equation can be used to calculate the COP413C current drain.

$$I_c = I_q + (V \times 20 \times F_i) + (V \times 1280 \times F_i / D_v)$$

where I_c = chip current drain in microamps

I_q = quiescent leakage current (from curve)

F_i = CKI frequency in megahertz

V = chip V_{CC} in volts

D_v = divide by option selected

For example, at 5V V_{CC} and 400 kHz (divide by 8),

$$I_c = 30 + (5 \times 20 \times 0.4) + (5 \times 1280 \times 0.4/8)$$

$$I_c = 30 + 40 + 320 = 390 \mu A$$

OSCILLATOR OPTIONS

There are two options available that define the use of CKI and CKO.

- Crystal-Controlled Oscillator. CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 8.
- RC-Controlled Oscillator. CKI is configured as a single pin RC-controlled Schmitt trigger oscillator. The instruction cycle time equals the oscillation frequency divided by 4. CKO is NC.

The RC oscillator is not recommended in systems that require accurate timing or low current. The RC oscillator draws more current than an external oscillator (typically an additional 100 μA at 5V). However, when the part halts, it stops with CKI high and the halt current is at the minimum.

Note: $15k \leq R \leq 150k$, $50 pF \leq C \leq 150 pF$									

Functional Description (Continued)

I/O CONFIGURATIONS

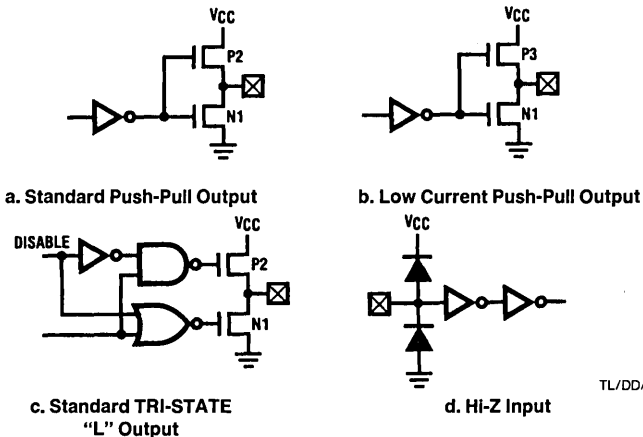

COP413C outputs have the following configurations, illustrated in Figure 7:

- a. Standard SO, SK Output. A CMOS push-pull buffer with an N-channel device to ground in conjunction with a P-channel device to V_{CC}, compatible with CMOS and LSTTL.
- b. Low Current G Output. This is the same configuration as (a) above except that the sourcing current is much less.
- c. Standard TRI-STATE L Output. L output is a CMOS output buffer similar to (a) which may be disabled by program control.

The SI and $\overline{\text{RESET}}$ inputs are Hi-Z inputs (Figure 7d).

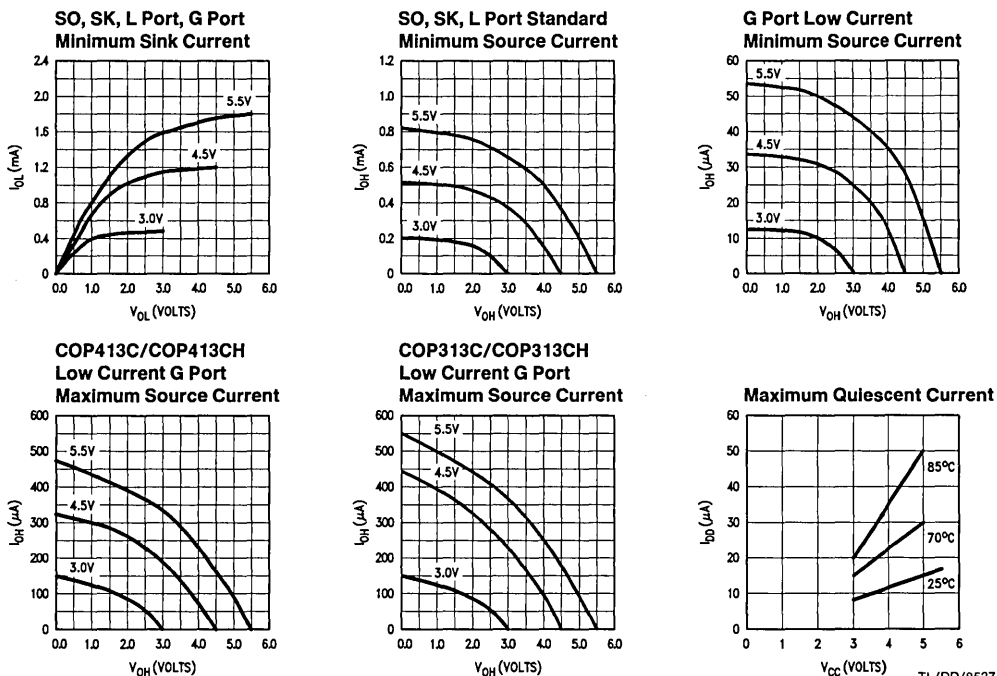

When using the G I/O port as an input, set the output register to a logic "1" level. The P-channel device will act as a pull-up load. When using the L I/O port as an input, disable the L drivers with the LEI instruction. The drivers are then in TRI-STATE mode and can be driven externally.

All output drivers use one or more of three common devices numbered 1 to 3. Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in Figure 8 for each of these devices to allow the designer to effectively use these I/O configurations.

COP413C Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP413C instruction set.

TABLE II. COP413C Instruction Set Table Symbols

Symbol	Definition	Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS		INSTRUCTION OPERAND SYMBOLS	
A	4-bit Accumulator	d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
B	6-bit RAM Address Register	r	2-bit Operand Field, 0–3 binary (RAM Register Select)
Br	Upper 2 bits of B (register address)	a	9-bit Operand Field, 0–511 binary (ROM Address)
Bd	Lower 4 bits of B (digit address)	y	4-bit Operand Field, 0–15 binary (Immediate Data)
C	1-bit Carry Register	RAM(s)	Contents of RAM location addressed by s
EN	4-bit Enable Register	ROM(t)	Contents of ROM location addressed by t
G	4-bit Register to latch data for G I/O Port	OPERATIONAL SYMBOLS	
L	8-bit TRI-STATE I/O Port	+	Plus
M	4-bit contents of RAM Memory pointed to by B Register	–	Minus
PC	9-bit ROM Address Register (program counter)	→	Replaces
Q	8-bit Register to latch data for L I/O Port	↔	Is exchanged with
SA	9-bit Subroutine Save Register A	=	Is equal to
SB	9-bit Subroutine Save Register B	\bar{A}	The one's complement of A
SIO	4-bit Shift Register and Counter	⊕	Exclusive-OR
SK	Logic-Controlled Clock Output	:	Range of values

		3A	0011 1010			
XAS		4F	0100 1111	A \leftrightarrow SIO, C \rightarrow SKL	None	Exchange A with SIO

Note 1: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 2: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP413C programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register.) If SIO is selected as a shift register, an XAS instruction must be performed once every four instruction cycle times to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower eight bits of the ROM address register PC with the contents of ROM addressed by the 9-bit word, PC₈, A, M. PC₈ is not affected by this instruction.

Note: JID uses two instruction cycles if executed, one if skipped.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 9-bit word PC₈, A, M. LQID can be used for table look-up or code conversion such as BCD to 7-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB) and replaces the least significant eight bits of the PC as follows: A → PC_{7:4}, RAM(B) → PC_{3:0}, leaving PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SB → SA → PC), restoring the saved value of the PC to continue sequential program execution. Since LQID pushes SA → SB, the previous contents of SB are lost.

Note: LQID uses two instruction cycles if executed, one if skipped.

INSTRUCTION SET NOTES

- The first word of a COP413C program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths take the same number of cycle times whether instructions are skipped or executed (except JID and LQID).
- The ROM is organized into eight pages of 64 words each. The program counter is a 9-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID, or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: A JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word in page 3 or 7 will access data in the next group of four pages.

COPS Programming Manual

For detailed information on writing COPS programs, the COPS Programming Manual 424410284-001 provides an in-depth discussion of the COPS architecture, instruction set and general techniques of COPS programming. This manual is written with the programmer in mind.

OPTION LIST—OSCILLATOR SELECTION

The oscillator option selected must be sent in with the EPROM of ROM Code for masking into the COP413C. Select the appropriate option, make a photocopy of the table and send it with the EPROM.

COP413C/COP313C

Option 1: Oscillator selection

- = 0 Ceramic Resonator input frequency divided by 8. CKO is oscillator output.
- = 1 Single pin RC controlled oscillator divided by 4. CKO is no connection.

Note: The following option information is to be sent to National along with the EPROM.

Option 1: Value = ____ is Oscillator Selected.

PRELIMINARY

COP414L/COP314L Single-Chip N-Channel Microcontrollers

General Description

The COP414L Single-Chip N-Channel Microcontrollers are members of the COPSTM family, fabricated using N-channel, silicon gate MOS technology. This Controller Oriented Processor is a complete microcomputer containing all system timing, internal logic, ROM, RAM and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP414L is an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Controller Oriented Processor at a low end-product cost.

The COP314L is an exact functional equivalent but extended temperature version of COP414L.

The COP414L can be emulated by the COP404C. The COP401L should be used for exact emulation.

Features

- Late waterfab programming of ROM and I/O for fast delivery of units
- Low cost
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- 15 I/O lines
- Two-level subroutine stack
- 16 μ s instruction time
- Single supply operation (4.5V–6.3V)
- Low current drain (6 mA max)
- Internal binary counter register with MICROWIRE™ serial I/O capability
- General purpose and TRI-STATE® outputs
- LSTTL/CMOS compatible in and out
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device
 - COP314L (–40°C to +85°C)
- Wider supply range (4.5V–6.3V) optionally available

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at Any Pin Relative to GND	-0.5V to +10V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	-65°C to +150°C
Lead Temperature (Soldering, 10 sec.)	300°C

Power Dissipation COP414L	0.65W at 25°C 0.3W at 70°C
Total Source Current	120 mA
Total Sink Current	100 mA

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics 0°C ≤ T_A ≤ +70°C, 4.5V ≤ V_{CC} ≤ 6.3V unless otherwise noted

Parameter	Conditions	Min	Max	Units
Standard Operating Voltage (V _{CC})		4.5	6.3	V
Power Supply Ripple (Note 1)	Peak to Peak		0.5	V
Operating Supply Current	All Inputs and Outputs Open		6	mA
Input Voltage Levels				
CKI Input Levels				
Ceramic Resonator Input (÷ 8)				
Logic High (V _{IH})	V _{CC} = Max	3.0		V
Logic High (V _{IH})	V _{CC} = 5V ± 5%	2.0		V
Logic Low (V _{IL})		-0.3	0.4	V
Schmitt Trigger Input (÷ 4)				
Logic High (V _{IH})		0.7 V _{CC}		V
Logic Low (V _{IL})		-0.3	0.6	V
RESET Input Levels	(Schmitt Trigger Input)			
Logic High		0.7 V _{CC}		V
Logic Low		-0.3	0.6	V
SO Input Level (Test Mode)	(Note 2)	2.0	2.5	V
All Other Inputs				
Logic High	V _{CC} = Max	3.0		V
Logic High	With TTL Trip Level Options	2.0		V
Logic Low	Selected, V _{CC} = 5V ± 5%	-0.3	0.8	V
Logic High	With High Trip Level Options	3.6		V
Logic Low	Selected	-0.3	1.2	V
Input Capacitance			7	pF
Hi-Z Input Leakage		-1	+1	μA
Output Voltage Levels				
LSTTL Operation	V _{CC} = 5V ± 10%			
Logic High (V _{OH})	I _{OH} = -25 μA	2.7		V
Logic Low (V _{OL})	I _{OL} = 0.36 mA		0.4	V
CMOS Operation				
Logic High	I _{OH} = -10 μA	V _{CC} - 1		V
Logic Low	I _{OL} = +10 μA		0.2	V

Note 1: V_{CC} voltage change must be less than 0.5V in a 1 ms period to maintain proper operation.

Note 2: SO output "0" level must be less than 0.8V for normal operation.

COP414L**DC Electrical Characteristics** $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$, $4.5\text{V} \leq V_{\text{CC}} \leq 6.3\text{V}$ unless otherwise noted (Continued)

Functional Description

A block diagram of the COP414L is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2V). When a bit is reset, it is a logic "0" (less than 0.8V).

All functional references to the COP414L also apply to the COP314L, and COP214L.

PROGRAM MEMORY

Program Memory consists of a 512-byte ROM. As can be seen by an examination of the COP414L instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words each.

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by the 9-bit subroutine save registers, SA and SB, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 128-bit RAM, organized as 4 data registers of 8 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper 2 bits (Br) select 1 of 4 data registers and lower 3 bits of the 4-bit Bd select 1 of 8 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it

may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3,15 instruction.

The most significant bit of Bd is not used to select a RAM digit. Hence each physical digit of RAM may be selected by two different values of Bd as shown in *Figure 4* below. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 and 15, but NOT between 7 and 8 (see Table III).

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

TL/DD/8814-5

Functional Description (Continued)

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Bd portion of the B register, to load 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions of the COP414L, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below.)

The G register contents are outputs to 4 general-purpose bidirectional I/O ports.

The Q register is an internal, latched, 8-bit register, used to hold data loaded from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M.

The SIO register functions as a 4-bit serial-in serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers.

The XAS instruction copies C into the SKL Latch. In the counter mode, SK is the output of SKL in the shift register mode, SK outputs SKL ANDed with internal instruction cycle clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN₃-EN₀).

1. The least significant bit of the enable register, EN₀, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, *decrementing* its value by one upon

each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.

2. EN₁ is not used. It has no effect on COP414L operation.
3. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN₂ disables the L drivers, placing the L I/O ports in a high-impedance input state.
4. EN₃, in conjunction with EN₀, affects the SO output. With EN₀ set (binary counter option selected) SO will output the value loaded into EN₃. With EN₀ reset (serial shift register option selected), setting EN₃ enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN₃ with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0". Table I provides a summary of the modes associated with EN₃ and EN₀.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μs. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below (Figure 5). The RESET pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC}. Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

RC ≥ 5 × Power Supply Rise Time TL/DD/8814-6

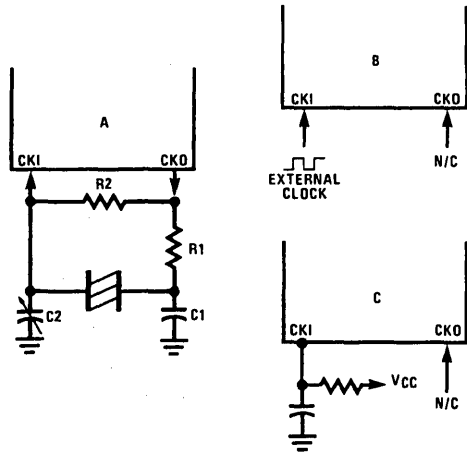

FIGURE 5. Power-Up Clear Circuit

TABLE I. Enable Register Modes—Bits EN₃ and EN₀

EN ₃	EN ₀	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = Clock If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = Clock If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

Functional Description (Continued)

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

TL/DD/8814-7

Ceramic Resonator Oscillator

Resonator Value	Components Values			
	R1 (Ω)	R2 (Ω)	C1 (pF)	C2 (pF)
455 kHz	4.7k	1M	220	220

RC Controlled Oscillator

R (k Ω)	C (pF)	Instruction Cycle Time in μ s
51	100	19 \pm 15%
82	56	19 \pm 13%

Note: 200 k Ω \geq R \geq 25 k Ω . 360 pF \geq C \geq 50 pF. Does not include tolerances.

FIGURE 6. COP414L Oscillator

OSCILLATOR

There are four basic clock oscillator configurations available as shown by *Figure 6*.

- Resonator Controlled Oscillator.** CKI and CKO are connected to an external ceramic resonator. The instruction cycle frequency equals the resonator frequency divided by 8.
- External Oscillator.** CKI is an external clock input signal. The external frequency is divided by 4 to give the instruction frequency time. CKO is no connection.

- RC Controlled Oscillator.** CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is no connection.

CKO PIN OPTIONS

In a resonator controlled oscillator system, CKO is used as an output to the resonator network. CKO is no connection for External or RC controlled oscillator.

I/O OPTIONS

COP414L inputs and outputs have the following optional configurations, illustrated in *Figure 7*:

- Standard**—an enhancement-mode device to ground in conjunction with a depletion-mode device to V_{CC} , compatible with LSTTL and CMOS input requirements. Available on SO, SK and all D and G outputs.
- Open-Drain**—an enhancement-mode device to ground only, allowing external pull-up as required by the user's application. Available on SO, SK and all D and G outputs.
- Push-Pull**—an enhancement-mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads. Available on SO and SK outputs only.
- Standard L**—same as a., but may be disabled. Available on L outputs only.
- Open Drain L**—same as b., but may be disabled. Available on L outputs only.
- An on-chip depletion load device to V_{CC} .
- A Hi-Z input which must be driven to a "1" or "0" by external components.

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of six devices (numbered 1-6, respectively). Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 8* for each of these devices to allow the designer to effectively use these I/O configurations in designing a COP414L system.

The SO, SK outputs can be configured as shown in a., b., or c. The G outputs can be configured as shown in a. or b. Note that when inputting data to the G ports, the G outputs should be set to "1". The L outputs can be configured as in d., or e.

An important point to remember if using configuration d. with the L drivers is that even when the L drivers are disabled, the depletion load device will source a small amount of current. (See *Figure 8*, device 2.) However, when the L port is used as input, the disabled depletion device CAN NOT be relied on to source sufficient current to pull an input to a logic "1".

COP414L Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP414L instruction set.

TABLE II. COP414L Instruction Set Table Symbols

Symbol	Definition	Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS		INSTRUCTION OPERAND SYMBOLS	
A	4-bit Accumulator	d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
B	6-bit RAM Address Register	r	2-bit Operand Field, 0–3 binary (RAM Register Select)
Br	Upper 2 bits of B (register address)	a	9-bit Operand Field, 0–511 binary (ROM Address)
Bd	Lower 4 bits of B (digit address)	y	4-bit Operand Field, 0–15 binary (Immediate Data)
C	1-bit Carry Register	RAM(s)	Contents of RAM location addressed by s
D	4-bit Data Output Port	ROM(t)	Contents of ROM location addressed by t
EN	4-bit Enable Register	OPERATIONAL SYMBOLS	
G	4-bit Register to latch data for G I/O Port	+	Plus
L	8-bit TRI-STATE I/O Port	–	Minus
M	4-bit contents of RAM Memory pointed to by B Register	→	Replaces
PC	9-bit ROM Address Register (program counter)	↔	Is exchanged with
Q	8-bit Register to latch data for L I/O Port	=	Is equal to
SA	9-bit Subroutine Save Register A	\bar{A}	The one's complement of A
SB	9-bit Subroutine Save Register B	⊕	Exclusive-OR
SIO	4-bit Shift Register and Counter	:	Range of values
SK	Logic-Controlled Clock Output

INPUT/OUTPUT INSTRUCTIONS						
ING		33 2A	[0011 0011] [0010 1010]	G → A	None	Input G Ports to A
INL		33 2E	[0011 0011] [0010 1110]	L _{7:4} → RAM(B) L _{3:0} → A	None	Input L Ports to RAM, A
OBD		33 3E	[0011 0011] [0011 1110]	Bd → D	None	Output Bd to D Outputs
OMG		33 3A	[0011 0011] [0011 1010]	RAM(B) → G	None	Output RAM to G Ports
XAS		4F	[0100 1111]	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 2)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: For additional information on the operation of the XAS, JID, and LQID instructions, see below.

Note 3: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 4: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 5: The machine code for the lower 4 bits of the LBI instruction equals the binary value of the "d" data *minus 1*, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 6: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Option List

The COP414L mask-programmable options are assigned numbers which correspond with the COP414L pins.

The following is a list of COP414L options. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

Option 1: L₄ Driver

- = 0: Standard output
- = 1: Open-drain output

Option 2: V_{CC} Pin

- = 0: Standard V_{CC}

Option 3: L₃ Driver

same as Option 1

Option 4: L₂ Driver

same as Option 1

Option 5: L₁ Driver

same as Option 1

Option 6: L₀ Driver

same as Option 1

Option 7: SI Input

- = 0: load device to V_{CC}
- = 1: Hi-Z Output

Option 8: SO Driver

- = 0: Standard output
- = 1: Open-drain output
- = 2: Push-pull output

Option 9: SK Driver

same as Option 8

Option 10:

- = 0: Ground Pin—no options available

Option 11: G₀ I/O Port

- = 0: Standard output
- = 1: Open-drain output

Option 12: G₁ I/O Port

same as Option 11

Option 13: G₂ I/O Port

same as Option 11

Option 14: G₃ I/O Port

same as Option 11

Option 15: CKO Output

- = 0: Clock output to ceramic resonator/crystal
- = 1: No connection

Option 16: CKI Input

- = 0: Oscillator input divided by 8 (500 kHz max)
- = 1: Single pin RC controlled oscillator divided by 4
- = 2: External Schmitt trigger level clock divided by 4

Option 17: RESET Input

- = 0: Load device to V_{CC}
- = 1: Hi-Z Input

Option 18: L₇ Driver

same as Option 1

Option 19: L₆ Driver

same as Option 1

Option 20: L₅ Driver

same as Option 1

Option 21: L Input Levels

- = 0: Standard TTL input levels ("0" = 0.8V, "1" = 2.0V)
- = 1: Higher voltage input levels ("0" = 1.2V, "1" = 3.6V)

Option 22: G Input Levels

same as Option 21

Option 23: SI Input Levels

same as Option 21

TEST MODE (NON-STANDARD OPERATION)

The SO output has been configured to provide for standard test procedures for the custom-programmed COP414L. With SO forced to logic "1", two test modes are provided, depending upon the value of SI:

- a. RAM and Internal Logic Test Mode (SI = 1)
- b. ROM Test Mode (SI = 0)

These special test modes should not be employed by the user; they are intended for manufacturing tests only.

COP414L Option List

Please fill out the Option List and send it with the EPROM.

Option Data

COP420/COP421/COP422 and COP320/COP321/COP322 Single-Chip N-Channel Microcontrollers

General Description

The COP420, COP421, COP422, COP320, COP321 and COP322 Single-Chip N-Channel Microcontrollers are members of the COPSTM family, fabricated using N-channel, silicon gate MOS technology. They are complete microcomputers containing all system timing, internal logic, ROM, RAM and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP421 is identical to the COP420, except with 19 I/O lines instead of 23; the COP422 has 15 I/O lines. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized Controller Oriented Processor at a low end-product cost.

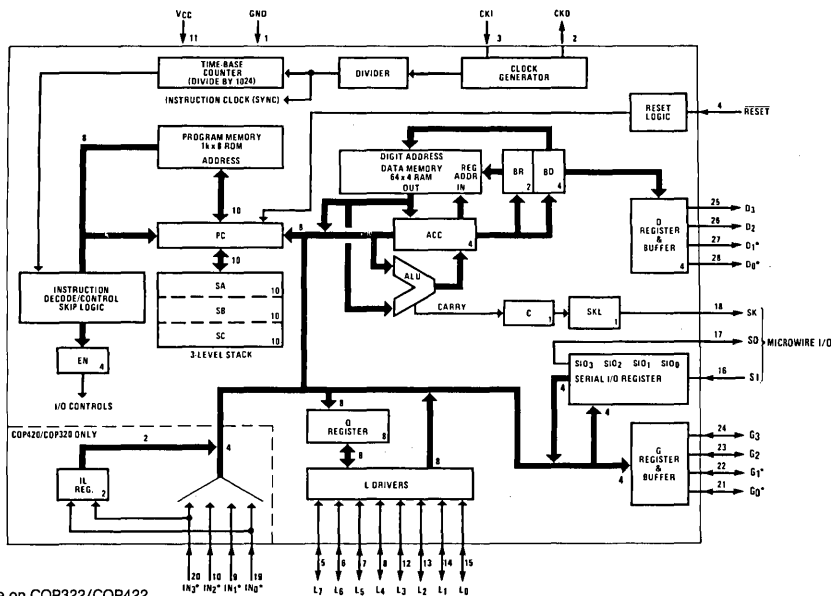

The COP320 is the extended temperature range version of the COP420 (likewise the COP321 and COP322 are the extended temperature range versions of the COP421/COP422). The COP320/321/322 are exact functional equivalents of the COP420/421/422.

Features

- Low cost
- Powerful instruction set
- 1k x 8 ROM, 64 x 4 RAM
- 23 I/O lines (COP420, COP320)
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 4.0 μ s instruction time
- Single supply operation
- Internal time-base counter for real-time processing
- Internal binary counter register with MICROWIRE™ compatible serial I/O capacity
- General purpose and TRI-STATE® outputs
- TTL/CMOS compatible in and out
- LED direct drive outputs
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device COP320/COP321/COP322 (-40°C to +85°C)
- COP420P emulator available

COP420/COP421/COP422/COP320/COP321/COP322

TL/DD/6921-1

COP420/COP421/COP422 and COP320/COP321/COP322**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at Any Pin	-0.3V to +7V
Operating Temperature Range	
COP420/COP421/COP422	0°C to 70°C
COP320/COP321/COP322	-40°C to +85°C
Storage Temperature Range	-65°C to +150°C
Total Sink Current	75 mA
Total Source Current	95 mA

Package Power Dissipation	750 mW at 25°C
24 and 28 pin	400 mW at 70°C
250 mW at 85°C	
Package Power Dissipation	650 mW at 25°C
20 pin	300 mW at 70°C
200 mW at 85°C	

Lead Temperature (soldering, 10 sec.) 300°C

Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

COP420/COP421/COP422**DC Electrical Characteristics** $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$, $4.5\text{V} \leq V_{CC} \leq 6.3\text{V}$ unless otherwise noted

Parameter	Conditions	Min	Max	Units
Operation Voltage		4.5	6.3	V
Power Supply Ripple	Peak to Peak (Note 3)		0.4	V

Functional Description COP420/COP421/COP422, COP320/COP321/COP322

For ease of reading this description, only COP420 and/or COP421 are referenced; however, all such references apply equally to the COP422, COP322, COP320 and/or COP321, respectively.

A block diagram of the COP420 is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2V). When a bit is reset, it is a logic "0" (less than 0.8V).

PROGRAM MEMORY

Program Memory consists of a 1,024 byte ROM. As can be seen by an examination of the COP420/421 instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 16 pages of 64 words each.

ROM addressing is accomplished by a 10-bit PC register. Its binary value selects one of the 1,024 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 10-bit binary count value. Three levels of subroutine nesting are implemented by the 10-bit subroutine save registers, SA, SB and SC, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of 256-bit RAM, organized as 4 data registers of 16 4-bit digits. RAM addressing is implemented by a 6-bit **B register** whose upper 2 bits (Br) select 1 of 4 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instructions based upon the 6-bit contents of the operand field of these instructions. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

INTERNAL LOGIC

The 4-bit **A register** (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Br and Bd portions of the B register, to load the input 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

Functional Description COP420/COP421/COP422, COP320/COP321/COP322 (Continued)

A **4-bit adder** performs the arithmetic and logic functions of the COP420/421, storing its results in A. It also outputs a carry bit to the 1-bit **C register**, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below.)

Four **general-purpose inputs, IN₃–IN₀**, are provided; IN₁, IN₂ and IN₃ may be selected, by a mask-programmable option, as Read Strobe, Chip Select and Write Strobe inputs, respectively, for use in MICROBUS applications.

The **D register** provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of Bd. The **G register** contents are outputs to 4 general-purpose bidirectional I/O ports. G₀ may be mask-programmed as an output for MICROBUS applications.

The **Q register** is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The **8 L drivers**, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M. L I/O ports can be directly connected to the segments of a multiplexed LED display (using the LED Direct Drive output configuration option) with Q data being outputted to the Sa–Sg and decimal point segments of the display.

The **SIO register** functions as a 4-bit serial-in/serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers. For example of additional parallel output capacity see **Application #2**.

The XAS instruction copies C into the **SKL latch**. In the counter mode, SK is the output of SKL; in the shift register mode, SK outputs SKL ANDed with the clock.

The **EN register** is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN₃–EN₀).

1. The least significant bit of the enable register, EN₀ selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0" occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting let each instruction cycle time. The data present at DI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.
2. With the EN₁ set the IN₁ input is enabled as an interrupt input. Immediately following an interrupt, EN₁ is reset to disable further interrupts.
3. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN₂ disables the L drivers, placing the L I/O ports in a high impedance input state.
4. EN₃, in conjunction with EN₀, affects the SO output. With EN₀ set (binary counter option selected) SO will output the value loaded into EN₃. With EN₀ reset (serial shift register option selected), setting EN enables SO as the output of the SIO shift register outputting serial shifted data each instruction time. Resetting EN₃ with the serial shift register option selected disables SO as the shift register output data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0". The table below provides summary of the modes associated with EN₃ and EN₁.

OSCILLATOR

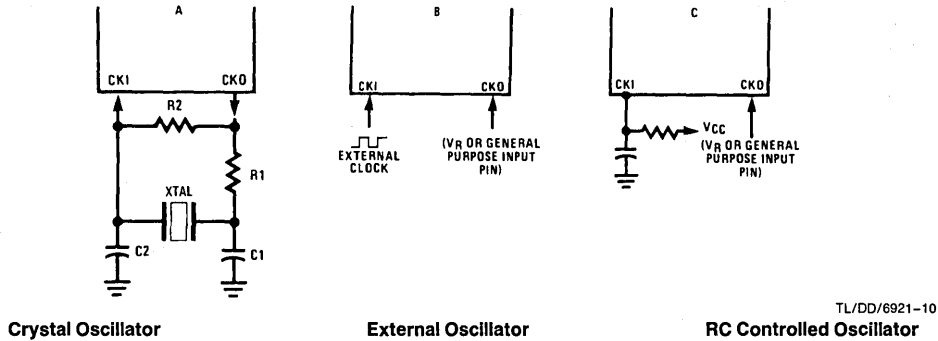

There are three basic clock oscillator configurations available as shown by *Figure 8*.

- a. Crystal Controlled Oscillator.** CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 16 (optional by 8).
- b. External Oscillator.** CKI is an external clock input signal. The external frequency is divided by 16 (optional by 8) to give the instruction cycle time. CKO is now available to be used as the RAM power supply (V_R) of as a general purpose input.
- c. RC Controlled Oscillator.** CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is available for non-timing functions.

Enable Register Modes—Bits EN₃ and EN₀

EN ₃	EN ₀	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = CLOCK If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = CLOCK If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

Functional Description COP420/COP421/COP422, COP320/COP321/COP322 (Continued)

TL/DD/6921-10

Crystal Oscillator

Crystal Value	Component Values			
	R1(Ω)	R2(Ω)	C1(pF)	C2(pF)
4 MHz	4.7k	1M	22	22
3.58 MHz	3.3k	1M	22	27

RC Controlled Oscillator

R(kΩ)	C(pF)	Instruction Cycle Time (μs)
12	100	5 ± 20%
6.8	220	5.3 ± 23%
8.2	300	8 ± 29%
22	100	8.6 ± 16%

Note: 50 kΩ ≥ R ≥ 5 kΩ
360 pF ≥ C ≥ 50 pF

FIGURE 8. COP420/421/COP320/321 Oscillator

CKO PIN OPTIONS

In a crystal controlled oscillator system, CKO is used as an output to the crystal network. As an option CKO can be a general purpose input, read into bit 2 of A (accumulator) upon execution of an INIL instruction. As another option, CKO can be a RAM power supply pin (VR), allowing its connection to a standby/backup power supply to maintain the integrity of RAM data with minimum power drain when the main supply is inoperative or shut down to conserve power. Using either option is appropriate in applications where the COP420/421 system timing configuration does not require use of the CKO pin.

RAM KEEP-ALIVE OPTION (NOT AVAILABLE ON COP422)

Selecting CKO as the RAM power supply (VR) allows the user to shut off the chip power supply (VCC) and maintain data in the RAM. To insure that RAM data integrity is maintained, the following conditions must be met:

1. RESET must go low before VCC goes below spec during power off; VCC must be within spec before RESET goes high on power up.
2. VR must be within the operating range of the chip, and equal to VCC ± 1V during normal operation.
3. VR must be ≥ 3.3V with VCC off.

INTERRUPT

The following features are associated with the IN1 interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- a. The interrupt, once acknowledged as explained below, pushes the next sequential program counter address (PC

- + 1) onto the stack, pushing in turn the contents of the other subroutine-save registers to the next lower level (PC + 1 → SA → SB → SC). Any previous contents of SC are lost. The program counter is set to hex address 0FF (the last word of page 3) and EN1 is reset.
- b. An interrupt will be acknowledged only after the following conditions are met:
 1. EN1 has been set.
 2. A low-going pulse ("1" to "0") at least two instruction cycles wide occurs on the IN1 input.
 3. A currently executing instruction has been completed.
 4. All successive transfer of control instructions and successive LBIs have been completed (e.g., if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed.
- c. Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon popping of the stack. For example, if an interrupt occurs during the execution of ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at hex address 0FF. At the end of the interrupt routine, a RET instruction is executed to "pop" the stack and return program control to the instruction following the original ASC. At this time, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines and LQID instructions should not be nested within the interrupt service routine, since their

Functional Description COP420/COP421/COP422, COP320/COP321/COP322 (Continued)

popping the stack will enable any previously saved main program skips, interfering with the orderly execution of the interrupt routine.

- d. The first instruction of the interrupt routine at hex address 0FF must be a NOP.
- e. A LEI instruction can be put immediately before the RET to re-enable interrupts.

INITIALIZATION

The Reset Logic, internal to the COP420/421, will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the $\overline{\text{RESET}}$ pin as shown below. The $\overline{\text{RESET}}$ pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC} .

Initialization will occur whenever a logic "0" is applied to the $\overline{\text{RESET}}$ input, provided it stays low for at least three instruction cycle times.

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

TL/DD/6921-13

FIGURE 7. Power-Up Clear Circuit

I/O OPTIONS

COP420/421 outputs have the following optional configurations, illustrated in *Figure 9a*:

- a. **Standard**—an enhancement-mode device to ground in conjunction with a depletion-mode device to V_{CC} , compatible with TTL and CMOS input requirements. Available on SO, SK, and all D and G outputs.
- b. **Open-Drain**—an enhancement-mode device to ground only, allowing external pull-up as required by the user's application. Available on SO, SK, and all D and G outputs.
- c. **Push-Pull**—An enhancement-mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads. Available on SO and SK outputs only.
- d. **Standard L**—same as a., but may be disabled. Available on L outputs only.
- e. **Open Drain L**—same as b., but may be disabled. Available on L outputs only.

Functional Description COP420/COP421/COP422, COP320/COP321/COP322 (Continued)

- f. **LED Direct Drive**—an enhancement-mode device to ground and to V_{CC} , meeting the typical current sourcing requirements of the segments of an LED display. The sourcing device is clamped to limit current flow. These devices may be turned off under program control (See Functional Description, EN Register), placing the outputs in a high-impedance state to provide required LED segment blanking for a multiplexed display.
- g. **TRI-STATE Push-Pull**—an enhancement-mode device to ground and V_{CC} . These outputs are TRI-STATE outputs, allowing for connection of these outputs to a data bus shared by other bus drivers.

COP420/COP421 inputs have the following optional configurations:

- h. An on-chip depletion load device to V_{CC} .
- i. A Hi-Z input which must be driven to a "1" or "0" by external components.

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of six devices (numbered 1–6, respectively). Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 9b* for each

of these devices to allow the designer to effectively use these I/O configurations in designing a COP420/421 system.

The SO, SK outputs can be configured as shown in *a.*, *b.*, or *c.* The D and G outputs can be configured as shown in *a.* or *b.* Note that when inputting data to the G ports, the G outputs should be set to "1." The L outputs can be configured as in *d.*, *e.*, *f.* or *g.*

An important point to remember if using configuration *d.* or *f.* with the L drivers is that even when the L drivers are disabled, the depletion load device will source a small amount of current (see *Figure 9b*, device 2); however, when the L lines are used as input, the disabled depletion device can *not* be relied on to source sufficient current to pull an input to logic "1".

COP421

If the COP420 is bonded as a 24-pin device, it becomes the COP421, illustrated in *Figure 2*, COP420/421 Connection Diagrams. Note that the COP421 does not contain the four general purpose IN inputs (IN_3 – IN_0). Use of this option precludes, of course, use of the IN options and interrupt feature. All other options are available for the COP421.

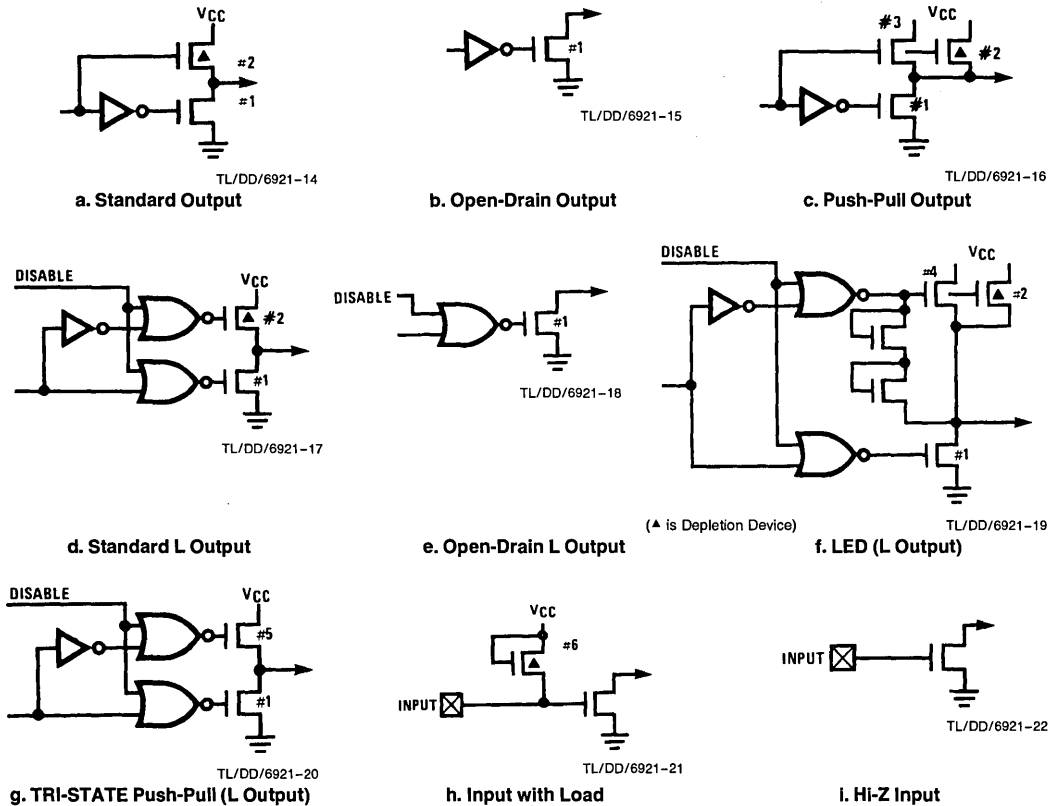

FIGURE 9a. Input/Output Configurations

L-Bus Considerations

False states may be generated on L₀-L₇ during the execution of the CAMQ instruction. The L-ports should not be used as clocks for edge sensitive devices such as flip-flops, counters, shift registers, etc. The following short program illustrates this situation.

START:

```
CLRA      ;ENABLE THE Q
LEI  4    ;REGISTER TO L LINES
LBI  TEST
STII  3
AISC  12
```

LOOP:

```
LBI  TEST ;LOAD Q WITH X'C3
CAMQ
JP   LOOP
```

In this program the internal Q register is enabled onto the L lines and a steady bit pattern of logic highs is output on L₀, L₁, L₆, L₇, and logic lows on L₂-L₅ via the two-byte CAMQ instruction. Timing constraints on the device are such that the Q register may be temporarily loaded with the second byte of the CAMQ opcode (X'3C) prior to receiving the valid data pattern. If this occurs, the opcode will ripple onto the L lines and cause negative-going glitches on L₀, L₁, L₆, L₇, and positive glitches on L₂-L₅. Glitch durations are under 2 microseconds, although the exact value may vary due to data patterns, processing parameters, and L line loading. These false states are peculiar only to the CAMQ instruction and the L lines.

Instruction Set

Table I is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table II provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP420/COP421/COP422 instruction set.

TABLE I. COP420/421/422/320/321/322 Instruction Set Table Symbols

Symbol	Definition	Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS		INSTRUCTION OPERAND SYMBOLS	
A	4-bit Accumulator	d	4-bit Operand Field, 0-15 binary (RAM Digit Select)
B	6-bit RAM Address Register	r	2-bit Operand Field, 0-3 binary (RAM Register Select)
Br	Upper 2 bits of B (register address)	a	10-bit Operand Field, 0-1023 binary (ROM Address)
Bd	Lower 4 bits of B (digit address)	y	4-bit Operand Field, 0-15 binary (Immediate Data)
C	1-bit Carry Register	RAM(s)	Contents of RAM location addressed by s
D	4-bit Data Output Port	ROM(t)	Contents of ROM location addressed by t
EN	4-bit Enable Register		
G	4-bit Register to latch data for G I/O Port		
IL	Two 1-bit latches associated with the IN_3 or IN_0 inputs		
IN	4-bit Input Port		
L	8-bit TRI-STATE I/O Port		
M	4-bit contents of RAM Memory pointed to by B Register		
PC	8-bit ROM Address Register (program counter)		
Q	8-bit Register to latch data for L I/O Port		
SA	10-bit Subroutine Save Register A		
SB	10-bit Subroutine Save Register B		
SC	10 Subroutine Save Register A		
SIO	4-bit Shift Register and Counter		
SK	Logic-Controlled Clock Output		
		OPERATIONAL SYMBOLS	
		+	Plus
		-	Minus
		→	Replaces
		↔	Is exchanged with
		=	Is equal to
		\bar{A}	The one's complement of A
		⊕	Exclusive-OR
		:	Range of values

TABLE II. COP420/421/422/320/321/322 Instruction Set

Mnemonic	Operand	Hex Code	Machine Language Code (Binary)	Data Flow	Skip Conditions	Description
ARITHMETIC INSTRUCTIONS						
ASC		30	0011 0000	$A + C + \text{RAM}(B) \rightarrow A$ $\text{Carry} \rightarrow C$	Carry	Add with Carry, Skip on Carry
ADD		31	0011 0001	$A + \text{RAM}(B) \rightarrow A$	None	Add RAM to A
ADT		4A	0100 1010	$A + 10_{10} \rightarrow A$	None	Add Ten to A
AISC	y	5-	0101 y	$A + y \rightarrow A$	Carry	Add immediate, Skip on Carry ($y \neq 0$)

XAS		4F	<u>0100</u> <u>1111</u>	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 3)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit register.

Note 2: The ININ instruction is not available on the COP421/COP321 and COP422/COP322 since these devices do not contain the IN inputs.

Note 3: For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.

Note 4: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 5: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 6: LBI is a single-byte instruction if d = 0, 9, 10, 11, 12, 13, 14, or 15. The machine code for the lower 4 bits equals the binary value of the "d" data *minus 1*, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 7: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP420/421 programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If

SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the *contents* of ROM addressed by the 10-bit word, PC_{9:8}, A, M. PC₉ and PC₈ are not affected by this instruction.

Note that JID requires 2 instruction cycles to execute.

Description of Selected Instructions (Continued)

INIL INSTRUCTION

INIL (Input IL Latches to A) inputs 2 latches, IL_3 and IL_0 (see Figure 10) and CKO into A. The IL_3 and IL_0 latches are set if a low-going pulse ("1" to "0") has occurred on the IN_3 and IN_0 inputs since the last INIL instruction, provided the input pulse stays low for at least two instruction times. Execution of an INIL inputs IL_3 and IL_0 into A_3 and A_0 respectively, and resets these latches to allow them to respond to subsequent low-going pulses on the IN_3 and IN_0 lines. If CKO is mask programmed as a general purpose input, an INIL will input the state of CKO into A_2 . If CKO has not been so programmed, a "1" will be placed in A_2 . A "0" is always placed in A_1 upon the execution of an INIL. The general purpose inputs IN_3 - IN_0 are input to A upon execution of an ININ instruction. (See Table II, ININ instruction.) INIL is useful in recognizing pulses of short duration or pulses which occur too often to be read conveniently by an ININ instruction.

Note: IL latches are not cleared on reset.

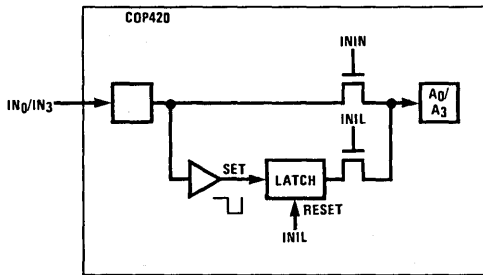

FIGURE 10

TL/DD/6921-25

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 10-bit word PC_9 , PC_8 , A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack ($PC + 1 \rightarrow SA \rightarrow SB \rightarrow SC$) and replaces the least significant 8 bits of PC as follows: $A \rightarrow PC_{7,4}$, $RAM(B) \rightarrow PC_{3,0}$, leaving PC_9 and PC_8 unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" ($SC \rightarrow SB \rightarrow SA \rightarrow PC$), restoring the saved value of PC to continue sequential program execu-

tion. Since LQID pushes $SB \rightarrow SC$, the previous contents of SC are lost. Also, when LQID pops the stack, the previously pushed contents of SB are left in SC. The net result is that the content of SB are placed in SC ($SB \rightarrow SC$). Note that LQID takes two instruction cycle times to execute.

SKT INSTRUCTION

The SKT (Skip On Timer) instruction tests the state of an internal 10-bit time-base counter. This counter divides the instruction cycle clock frequency by 1024 and provides a latched indication of counter overflow. The SKT instruction tests this latch, executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction, therefore, allow the COP420/421 to generate its own time-base for real-time processing rather than relying on an external input signal.

For example, using a 2.097 MHz crystal as the time-base to the clock generator, the instruction cycle clock frequency will be 131 kHz (crystal frequency $\div 16$) and the binary counter output pulse frequency will be 128 Hz. For time-of-day or similar real-time processing, the SKT instruction can call a routine which increments a "seconds" counter every 128 ticks.

INSTRUCTION SET NOTES

- The first word of a COP420/421 program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths take the same number of cycle times whether instructions are skipped or executed except JID and LQID. LQID and JID take two cycle times if executed and one if skipped.
- The ROM is organized into 16 pages of 64 words each. The Program Counter is a 10-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3, 7, 11 or 15 will access data in the next group of four pages.

Option List

The COP420/421/422 mask-programmable options are assigned numbers which correspond with the COP420 pins.

The following is a list of COP420 options. When specifying a COP421 or COP422 chip, Options 9, 10, 19, 20 and 29 must all be set to zero. When specifying a COP422 chip, Options 21, 22, 27 and 28 must also be zero, and Option 2 must not be a 1. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

Option 1 = 0: Ground—no options available

Option 2: CKO Pin

- = 0: clock generator output to crystal
0 not available if option 3 = 4 or 5
- = 1: Pin is RAM power supply (V_R) input
(Not available on COP422/COP322)
- = 2: general purpose input with load device
- = 4: general purpose Hi Z input

Option 3: CKI Input

- = 0: crystal input divided by 16
- = 1: crystal input divided by 8
- = 2: TTL external clock input divided by 16
- = 3: TTL external clock input divided by 8
- = 4: single-pin RC controlled oscillator ($\div 4$)
- = 5: External Schmitt trigger clock input ($\div 4$)

Option 4: RESET Pin

- = 0: load devices to V_{CC}
- = 1: Hi-Z input

Option 5: L₇ Driver

- = 0: Standard output (*Figure 9D*)
- = 1: Open-Drain output (E)
- = 2: LED direct drive output (F)
- = 3: TRI-STATE push-pull output (G)

Option 6: L₆ Driver

same as Option 5

Option 7: L₅ Driver

same as Option 5

Option 8: L₄ Driver

same as Option 5

Option 9: IN₁ Input

- = 0: load devices to V_{CC} (H)
- = 1: Hi-Z input (I)

Option 10: IN₂ Input

same as Option 9

Option 11 = 0: V_{CC} Pin—no options available

Option 12: L₃ Driver

same as Option 5

Option 13: L₂ Driver

same as Option 5

Option 14: L₁ Driver

same as Option 5

Option 15: L₀ Driver

same as Option 5

Option 16: SI Input
same as Option 9

Option 17: SO Driver

- = 0: standard output (A)
- = 1: open-drain output (B)
- = 2: push-pull output (C)

Option 18: SK Driver

same as Option 17

Option 19: IN₀ Input

same as Option 9

Option 20: IN₃ Input

same as Option 9

Option 21: G₀ I/O Port

- = 0: Standard output (A)
- = 1: Open-Drain output (B)

Option 22: G₁ I/O Port

same as Option 21

Option 23: G₂ I/O Port

same as Option 21

Option 24: G₃ I/O Port

same as Option 21

Option 25: D₃ Output

- = 0: Standard output (A)
- = 1: Open-Drain output (B)

Option 26: D₂ Output

same as Option 25

Option 27: D₁ Output

same as Option 25

Option 28: D₀ Output

same as Option 25

Option 29: COP Function

= 0: normal operation

Option 30: COP Bonding

- = 0: COP420 (28-pin device)
- = 1: COP421 (24-pin device)
- = 2: 28- and 24-pin device
- = 3: COP422 (20-pin device)
- = 4: 28- and 20-pin device
- = 5: 24- and 20-pin device
- = 6: 28-, 24- and 20-pin device

Option 31: In Input Levels

- = 0: normal input levels
- = 1: Higher voltage input levels
("0" = 1.2V, "1" = 3.6V)

Option 32: G Input Levels

same as Option 31

Option 33: L Input Levels

same as Option 31

Option 34: CKO Input Levels

same as Option 31

Option 35: SI Input Levels

same as Option 31

TEST MODE (Non-Standard Operation)

The SO output has been configured to provide for standard test procedures for the custom-programmed COP420. With SO forced to logic "1", two test modes are provided, depending upon the value of SI:

- RAM and Internal Logic Test Mode (SI = 1)
- ROM Test Mode (SI = 0)

These special test modes should not be employed by the user; they are intended for manufacturing test only.

APPLICATION #1: COP420 General Controller

Figure 8 shows an interconnect diagram for a COP420 used as a general controller. Operation of the system is as follows:

- The L₇-L₀ outputs are configured as LED Direct Drive outputs, allowing direct connection to the segments of the display.

- The D₃-D₀ outputs drive the digits of the multiplexed display directly and scan the columns of the 4 x 4 keyboard matrix.
- The IN₃-IN₀ inputs are used to input the 4 rows of the keyboard matrix. Reading the IN lines in conjunction with the current value of the D outputs allows detection, debouncing, and decoding of any one of the 16 keyswitches.
- CKI is configured as a single-pin oscillator input allowing system timing to be controlled by a single-pin RC network. CKO is therefore available for use as a V_R RAM power supply pin. RAM data integrity is thereby assured when the main power supply is shut down (see RAM Keep-Alive option description).
- SI is selected as the input to a binary counter input. With SIO used as a binary counter, SO and SK can be used as general purpose outputs.
- The 4 bidirectional G I/O ports (G₃-G₀) are available for use as required by the user's application.

APPLICATION #2: MUSICAL ORGAN AND MUSIC BOX

Software is available on Dial-A-Helper.

Play Mode: Twenty-five musical keys and 25 LEDs are provided to denote F to F with half notes in between. All the keys and LEDs are directly detected and driven by the microprocessor. Depression of the key will give the corresponding musical note and light up the corresponding LED.

Clear: Memory is provided to store a played tune. Depression of the CLEAR key erases the memory and the microprocessor is ready to store new musical notes. A maximum of 28 notes can be stored where each note can be of one to eight musical beats. (Two bytes of memory are required to store one musical note. Any note longer than eight musical beats will require additional memory space for storage.)

Playback: Depression of this button will playback the tune stored in the memory since last "clear."

Preprogrammed Tunes: There are ten preprogrammed tunes (each has an average of 55 notes) masked in the chip. Any tune can be recalled by depressing the "Tune Button" followed by the corresponding "Sharp Key."

Learn Mode: This mode is for the player to learn the ten preprogrammed tunes. By pressing the "Learn Button" followed by the corresponding "Sharp Key," the LEDs will be lighted up one by one to indicate the notes of the selected tune. The LED will remain "on" until the player presses the correct musical key; the LED for the next note will then be lighted up.

Pause: In addition to the 25 musical keys, there is a special pause key. The depression of this key generates a blank note to the memory.

Note: In the Learn Mode when playing "Oh Susanna," the pause key must be used.

Tempo: This is a control input to the musical beat time oscillator for varying the speed of the musical tunes.

Vibrato: This is a switch control to vary the frequency vibration of the note.

Tunes Listing: The following is a listing of the ten preprogrammed tunes: 1) Jingle Bells, 2) Twinkle, Twinkle Little Star, 3) Happy Birthday, 4) Yankee Doodle, 5) Silent Night, 6) This Old Man, 7) London Bridge Is Falling Down, 8) Auld Lang Syne, 9) Oh Susanna, 10) Clementine.

Typical Applications

COP420L/COP421L/COP422L/COP320L/COP321L/ COP322L Single-Chip N-Channel Microcontrollers

General Description

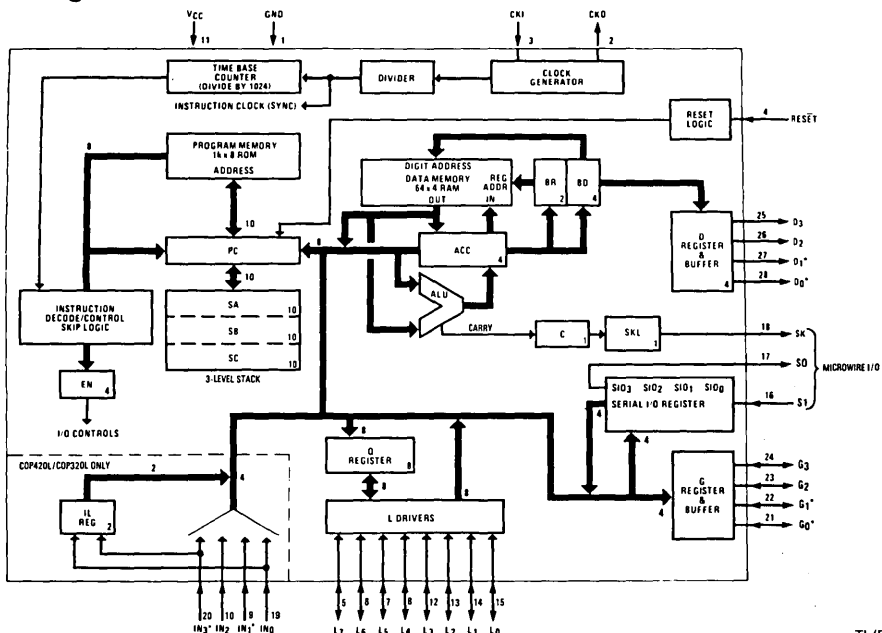

The COP420L, COP421L, COP422L, COP320L, COP321L, and COP322L Single-Chip N-Channel Microcontrollers are members of the COPSTM family, fabricated using N-channel, silicon gate MOS technology. These controller oriented processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture, and I/O scheme designed to facilitate keyboard input, display output, and BCD data manipulation. The COP421L and COP422L are identical to the COP420L, but with 19 and 15 I/O lines, respectively, instead of 23. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized controller oriented processor at a low end-product cost.

The COP320L, COP321L, and COP322L are exact functional equivalents, but extended temperature range versions, of the COP420L, COP421L, and COP422L respectively.

Features

- Low cost
- Powerful instruction set
- 1k x 8 ROM, 64 x 4 RAM
- 23 I/O lines (COP420L)
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 16 μ s instruction time
- Single supply operation (4.5V–6.3V)
- Low current drain (9 mA max)
- Internal time-base counter for real-time processing
- Internal binary counter register with MICROWIRE™ compatible serial I/O
- General purpose and TRI-STATE® outputs
- LSTTL/CMOS compatible in and out
- Direct drive of LED digit and segment lines
- Software/hardware compatible with other members of COP400 family
- Extended temperature range device—
COP320L/COP321L/COP322L (–40°C to +85°C)

COP420L/COP421L/COP422L**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at Any Pin Relative to GND	-0.5V to +10V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	-65°C to +150°C
Lead Temperature (Soldering, 10 sec.)	300°C

Power Dissipation		
COP420L/COP421L	0.75W at 25°C	0.4W at 70°C
COP422L	0.65W at 25°C	0.3W at 70°C

Total Source Current	120 mA
Total Sink Current	120 mA

Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics 0°C ≤ T_A ≤ +70°C, 4.5V ≤ V_{CC} ≤ 6.3V unless otherwise noted

Parameter	Conditions	Min	Max	Units
Standard Operating Voltage (V _{CC})		4.5	6.3	V
Power Supply Ripple (Notes 1, 4)	Peak to Peak		0.5	V
Operating Supply Current	All Inputs and Outputs Open		9	mA
Input Voltage Levels				
CKI Input Levels				
Crystal Input (÷32, ÷16, ÷8)				
Logic High (V _{IH})	V _{CC} = Max	3.0		V
Logic High (V _{IH})	V _{CC} = 5V ±5%	2.0		V
Logic Low (V _{IL})		-0.3	0.4	V
Schmitt Trigger Input (÷4)				
Logic High (V _{IH})		0.7 V _{CC}		V
Logic Low (V _{IL})		-0.3	0.6	V
RESET Input Levels	Schmitt Trigger Input			
Logic High		0.7 V _{CC}		V
Logic Low		-0.3	0.6	V
SO Input Level (Test Mode)	(Note 3)	2.0	2.5	V
All Other Inputs				
Logic High	V _{CC} = Max	3.0		V
Logic High	with TTL Trip Level Options	2.0		V
Logic Low	Selected, V _{CC} = 5V ±5%	-0.3	0.8	V
Logic High	with High Trip Level Options	3.6		V
Logic Low	Selected	-0.3	1.2	V
Input Capacitance (Note 4)			7	pF
Hi-Z Input Leakage		-1	+1	μA
Output Voltage Levels				
LSTTL Operation	V _{CC} = 5V ±10%			
Logic High (V _{OH})	I _{OH} = -25 μA	2.7		V
Logic Low (V _{OL})	I _{OL} = 0.36 ma		0.4	V
CMOS Operation (Note 2)	V _{CC} = 4.5V			
Logic High	I _{OH} = -10 μA	V _{CC} - 1		V
Logic Low	I _{OL} = +10 μA		0.2	V

Note 1: V_{CC} voltage change must be less than 0.5V in a 1 ms period to maintain proper operation.

Note 2: TRI-STATE and LED configurations are excluded.

Note 3: SO output "0" level must be less than 0.8V for normal operation.

Note 4: This parameter is only sampled and not 100% tested.

COP420L/COP421L/COP422L**DC Electrical Characteristics** $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$, $4.5\text{V} \leq V_{\text{CC}} \leq 6.3\text{V}$ unless otherwise noted (Continued)

Pin Descriptions

- L₇-L₀ 8 bidirectional I/O ports with TRI-STATE
- G₃-G₀ 4 bidirectional I/O ports
- D₃-D₀ 4 general purpose outputs
- IN₃-IN₀ 4 general purpose inputs (COP420L only)
- SI Serial input (or counter input)
- SO Serial output (or general purpose output)
- SK Logic-controlled clock (or general purpose output)
- CKI System oscillator input
- CKO System oscillator output or general purpose input
- RESET System reset input
- V_{CC} Power supply
- GND Ground

Functional Description

For ease of reading this description, only COP420L and/or COP421L are referenced; however, all such references apply also to COP320L, COP321L, COP322L, or COP422L.

A block diagram of the COP420L is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2V). When a bit is reset, it is a logic "0" (less than 0.8V).

PROGRAM MEMORY

Program Memory consists of a 1,024 byte ROM. As can be seen by an examination of the COP420L/421L instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 16 pages of 64 words each.

ROM addressing is accomplished by a 10-bit PC register. Its binary value selects one of the 1,024 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 10-bit binary count value. Three levels of subroutine nesting are implemented by the 10-bit subroutine save registers, SA, SB and SC, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 256-bit RAM, organized as 4 data registers of 16 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper 2 bits (Br) select 1 of 4 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instructions is based upon the 6-bit contents of the operand field of these instructions. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Br and Bd portions of the B register, to load and input 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions of the COP420/421L, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or

can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below.)

Four general-purpose inputs, IN_3 – IN_0 , are provided.

The D register provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of Bd. The D outputs can be directly connected to the digits of a multiplexed LED display.

The G register contents are outputs to 4 general-purpose bidirectional I/O ports. G I/O ports can be directly connected to the digits of a multiplexed LED display.

The Q register is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are outputted to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M. L I/O ports can be directly connected to the segments of a multiplexed LED display (using the LED Direct Drive output configuration option) with Q data being outputted to the Sa–Sg and decimal point segments of the display.

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers. For example of additional parallel output capacity see Application #2.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK outputs SKL ANDed with the clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN_3 – EN_0).

1. The least significant bit of the enable register, EN_0 , selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN_0 set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN_3 . With EN_0 reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.
2. With EN_1 set the IN_1 input is enabled as an interrupt input. Immediately following an interrupt, EN_1 is reset to disable further interrupts.
3. With EN_2 set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN_2 disables

Functional Description (Continued)

the L drivers, placing the L I/O ports in a high-impedance input state.

4. EN_3 , in conjunction with EN_0 , affects the SO output. With EN_0 set (binary counter option selected) SO will output the value loaded into EN_3 . With EN_0 reset (serial shift register option selected), setting EN_3 enables SO as the output of the SIO shift register, outputting serial shifted

data each instruction time. Resetting EN_3 with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0". The table below provides a summary of the modes associated with EN_3 and EN_0 .

Enable Register Modes—Bits EN_3 and EN_0

EN_3	EN_0	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = Clock If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = Clock If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

INTERRUPT

The following features are associated with the IN_1 interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- a. The interrupt, once acknowledged as explained below, pushes the next sequential program counter address ($PC + 1$) onto the stack, pushing in turn the contents of the other subroutine-save registers to the next lower level ($PC + 1 \rightarrow SA \rightarrow SB \rightarrow SC$). Any previous contents of SC are lost. The program counter is set to hex address 0FF (the last word of page 3) and EN_1 is reset.
- b. An interrupt will be acknowledged only after the following conditions are met:
 1. EN_1 has been set.
 2. A low-going pulse ("1" to "0") at least two instruction cycles wide occurs on the IN_1 input.
 3. A currently executing instruction has been completed.
 4. All successive transfer of control instructions and successive LBIs have been completed (e.g., if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed).
- c. Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon popping of the stack. For example if an interrupt occurs during the execution of ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at address 0FF. At the end of the interrupt routine, a RET instruction is executed to "pop" the stack and return program control to the instruction following the original ASC. At this time, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines and LQID instructions should not be

nested within the interrupt servicing routine since their popping the stack will enable any previously saved main program skips, interfering with the orderly execution of the interrupt routine.

- d. The first instruction of the interrupt routine at hex address 0FF must be a NOP.
- e. A LEI instruction can be put immediately before the RET to re-enable interrupts.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below. The RESET pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC} . Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

TL/DD/8825-7

$RC \geq 5 \times$ Power Supply Rise Time

Functional Description (Continued)

OSCILLATOR

There are three basic clock oscillator configurations available as shown by *Figure 4*.

- Crystal Controlled Oscillator.** CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 32 (optional by 16 or 8).
- External Oscillator.** CKI is an external clock input signal. The external frequency is divided by 32 (optional by 16 or 8) to give the instruction cycle time. CKO is now available to be used as the RAM power supply (V_R) or as a general purpose input.
- RC Controlled Oscillator.** CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is available as the RAM power supply (V_R) or as a general purpose input.

CKO PIN OPTIONS

In a crystal controlled oscillator system, CKO is used as an output to the crystal network. As an option CKO can be a general purpose input, read into bit 2 of A (accumulator) upon execution of an INIL instruction. As another option, CKO can be a RAM power supply pin (V_R), allowing its connection to a standby/backup power supply to maintain the integrity of RAM data with minimum power drain when the main supply is inoperative or shut down to conserve power. Using either option is appropriate in applications where the COP420L/421L system timing configuration does not require use of the CKO pin.

TL/DD/8825-8

Crystal Value	Component Values			
	R1 (Ω)	R2 (Ω)	C1 (pF)	C2 (pF)
455 kHz	4.7k	1M	220	220

FIGURE 4. COP420L/421L Oscillator

Functional Description (Continued)

I/O OPTIONS

COP420L/421L outputs have the following optional configurations, illustrated in *Figure 5*:

- a. **Standard**—an enhancement mode device to ground in conjunction with a depletion-mode device to V_{CC} , compatible with LSTTL and CMOS input requirements. Available on SO, SK, and all D and G outputs.
- b. **Open-Drain**—an enhancement-mode device to ground only, allowing external pull-up as required by the user's application. Available on SO, SK, and all D and G outputs.
- c. **Push-Pull**—An enhancement-mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads. Available on SO and SK outputs only.
- d. **Standard L**—same as a., but may be disabled. Available on L outputs only.
- e. **Open Drain L**—same as b., but may be disabled. Available on L outputs only.
- f. **LED Direct Drive**—an enhancement-mode device to ground and to V_{CC} , meeting the typical current sourcing requirements of the segments of an LED display. The sourcing device is clamped to limit current flow. These devices may be turned off under program control (see Functional Description, EN Register), placing the outputs in a high-impedance state to provide required LED segment blanking for a multiplexed display. Available on L outputs only.
- g. **TRI-STATE Push-Pull**—an enhancement-mode device to ground and V_{CC} . These outputs are TRI-STATE outputs, allowing for connection of these outputs to a data bus shared by other bus drivers. Available on L outputs only.

COP420L/COP421L inputs have the following optional configurations:

- h. An on-chip depletion load device to V_{CC} .
- i. A Hi-Z input which must be driven to a "1" or "0" by external components.

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of six devices (numbered 1–6, respectively). Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 6* for each of these devices to allow the designer to effectively use these I/O configurations in designing a COP420L/421L system.

The SO, SK outputs can be configured as shown in a., b., or c. The D and G outputs can be configured as shown in a. or b. Note that when inputting data to the G ports, the G outputs should be set to "1". The L outputs can be configured as in d., e., f. or g.

An important point to remember if using configuration d. or f. with the L drivers is that even when the L drivers are disabled, the depletion load device will source a small amount of current (see *Figure 6*, device 2); however, when the L lines are used as inputs, the disabled depletion device *cannot* be relied on to source sufficient current to pull an input to a logic 1.

COP421L

If the COP420L is bonded as a 24-pin device, it becomes the COP421L, illustrated in *Figure 2*, COP420L/421L Connection Diagrams. Note that the COP421L does not contain the four general purpose IN inputs (IN_3 – IN_0). Use of this option precludes, of course, use of the IN options and the interrupt feature. All other options are available for the COP421L.

COP422L

If the COP421L is bonded as a 20-pin device, it becomes the COP422L, as illustrated in *Figure 2*. Note that the COP422L contains all the COP421L pins except D_0 , D_1 , G_0 , and G_1 .

L-Bus Considerations

False states may be generated on L₀-L₇ during the execution of the CAMQ instruction. The L-ports should not be used as clocks for edge sensitive devices such as flip-flops, counters, shift registers, etc. the following short program that illustrates this situation.

```

START:
    CLRA      ;ENABLE THE Q
    LEI 4    ;REGISTER TO L LINES
    LBI TEST
    STII 3
    AISC 12

LOOP:
    LBI TEST ;LOAD Q WITH X'C3
    CAMQ
    JP LOOP
    
```

In this program the internal Q register is enabled onto the L lines and a steady bit pattern of logic highs is output on L₀, L₁, L₆, L₇, and logic lows on L₂-L₅ via the two-byte CAMQ instruction. Timing constraints on the device are such that the Q register may be temporarily loaded with the second byte of the CAMQ opcode (X'3C) prior to receiving the valid data pattern. If this occurs, the opcode will ripple onto the L lines and cause negative-going glitches on L₀, L₁, L₆, L₇, and positive glitches on L₂-L₅. Glitch durations are under 2 μs, although the exact value may vary due to data patterns, processing parameters, and L line loading. These false states are peculiar only to the CAMQ instruction and the L lines.

Typical Performance Characteristics

LED Output Source Current (High Current LED Option)

LED Output Source Current (Low Current LED Option)

LED Output Direct Segment and Digit Drive (High Current Options on L₀-L₇; Very High Current Options on D₀-D₃ and G₀-G₃)

LED Output Direct Segment Drive

Output Sink Current for SO and SK

Output Sink Current for L₀-L₇ and Standard Drive Option for D₀-D₃ and G₀-G₃

Output Sink Current for G₀-G₃ and D₀-D₃ with Very High Current Option

Output Sink Current for G₀-G₃ and D₀-D₃ (High Current Option)

COP420L/COP421L Instruction Set

Table I is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table II provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP410L/411L instruction set.

TABLE I. COP420L/421L Instruction Set Table Symbols

Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS	
A	4-bit Accumulator
B	6-bit RAM Address Register
Br	Upper 2 bits of B (register address)
Bd	Lower 4 bits of B (digit address)
C	1-bit Carry Register
D	4-bit Data Output Port
EN	4-bit Enable Register
G	4-bit Register to latch data for G I/O Port
IL	Two 1-bit Latches associated with the IN ₃ or IN ₀ inputs
IN	4-bit Input Port
L	8-bit TRI-STATE I/O Port
M	4-bit contents of RAM Memory pointed to by B Register
PC	10-bit ROM Address Register (program counter)
Q	8-bit Register to latch data for L I/O Port
SA	10-bit Subroutine Save Register A
SB	10-bit Subroutine Save Register B
SC	10-bit Subroutine Save Register C
SIO	4-bit Shift Register and Counter
SK	Logic-Controlled Clock Output

Symbol	Definition
INSTRUCTION OPERAND SYMBOLS	
d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
r	2-bit Operand Field, 0–3 binary (RAM Register Select)
a	10-bit Operand Field, 0–1023 binary (ROM Address)
y	4-bit Operand Field, 0–15 binary (Immediate Data)
RAM(s)	Contents of RAM location addressed by s
ROM(t)	Contents of ROM location addressed by t

OPERATIONAL SYMBOLS

+	Plus
–	Minus
→	Replaces
↔	Is exchanged with
=	Is equal to
\bar{A}	The ones complement of A

0100	1111									

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: The ININ instruction is only available on the 28-pin COP420L as the other devices do not contain the IN inputs.

Note 3: For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.

Note 4: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 5: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 6: LBI is a single-byte instruction if d = 0, 9, 10, 11, 12, 13, 14, or 15. The machine code for the lower 4 bits equals the binary value of the "d" data minus 1, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 7: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP420L/421L programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If

SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the contents of ROM addressed by the 10-bit word, PC_{9:8}, A, M. PC_{9:8}, A, M. PC₉ and PC₈ are not affected by this instruction.

Note that JID requires 2 instruction cycles to execute.

Description of Selected Instructions (Continued)

INIL INSTRUCTION

INIL (Input IL Latches to A) inputs 2 latches, IL_3 and IL_0 (see Figure 8) and CKO into A. The IL_3 and IL_0 latches are set if a low-going pulse ("1" to "0") has occurred on the IN_3 and IN_0 inputs since the last INIL instruction, provided the input pulse stays low for at least two instruction times. Execution of an INIL inputs IL_3 and IL_0 into A3 and A0 respectively, and resets these latches to allow them to respond to subsequent low-going pulses on the IN_3 and IN_0 lines. If CKO is mask programmed as a general purpose input, an INIL will input the state of CKO into A2. If CKO has not been so programmed, a "1" will be placed in A2. A "0" is always placed in A1 upon the execution of an INIL. The general purpose inputs IN_3 – IN_0 are input to A upon execution of an ININ instruction. (See Table II, ININ instruction.) INIL is useful in recognizing pulses of short duration or pulses which occur too often to be read conveniently by an ININ instruction. IL latches are *not cleared* on reset.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 10-bit word PC_9 , PC_8 , A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack ($PC + 1 \rightarrow SA \rightarrow SB \rightarrow SC$) and replaces the least significant 8 bits of PC as follows: $A \rightarrow PC_{7,4}$, $RAM(B) \rightarrow PC_{3,0}$, leaving PC_9 and PC_8 unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" ($SC \rightarrow SB \rightarrow SA \rightarrow PC$), restoring the saved value of PC to continue sequential program execution. Since LQID pushes $SB \rightarrow SC$, the previous contents of SC are lost. Also, when LQID pops the stack, the previously pushed contents of SB are left in SC. The net result is that the contents of SB are placed in SC ($SB \rightarrow SC$). Note the LQID takes two instruction cycle times to execute.

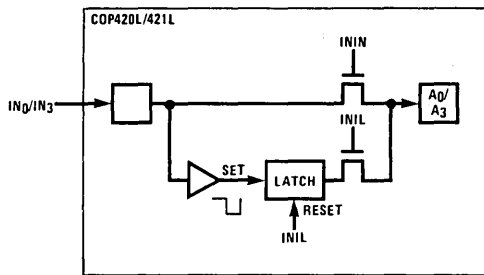

SKT INSTRUCTION

The SKT (Skip On Timer) instruction tests the state of an internal 10-bit time-base counter. This counter divides the instruction cycle clock frequency by 1024 and provides a latched indication of counter overflow. The SKT instruction tests this latch, executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction, therefore, allow the COP420L/421L to generate its own time-base for real-time processing rather than relying on an external input signal.

For example, using a 2.097 MHz crystal as the time-base to the clock generator, the instruction cycle clock frequency will be 65 kHz (crystal frequency \div 32) and the binary counter output pulse frequency will be 64 Hz. For time-of-day or similar real-time processing, the SKT instruction can call a routine which increments a "seconds" counter every 64 ticks.

INSTRUCTION SET NOTES

- The first word of a COP420L/421L program (ROM address 0) must be a CLR A (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths except JID and LQID take the same number of cycle times whether instructions are skipped or executed. JID and LQID instructions take 2 cycles if executed and 1 cycle if skipped.
- The ROM is organized into 16 pages of 64 words each. The Program Counter is a 10-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3, 7, 11, or 15 will access data in the next group of four pages.

FIGURE 8. INIL Hardware Implementation

Option List

The COP420L/421L mask-programmable options are assigned numbers which correspond with the COP420L pins.

The following is a list of COP420L options. When specifying a COP421L chip, Options 9, 10, 19, and 20 must all be set to zero. When specifying a COP422L chip, options 9, 10, 19, and 20 must all be set to zero; options 21 and 22 may not be set to one, three or five; and option 2 may not be set to one. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

The Option Table should be copied and sent in with your EPROM or disc.

- Option 1 = 0: Ground Pin—no options available
- Option 2: CKO Output
 = 0: clock generator output to crystal/resonator (0 not allowable value if Option 3 = 3)
 = 1: not an option
 = 2: general purpose input with load device to V_{CC}
 = 3: general purpose input, Hi-Z
- Option 3: CKI Input
 = 0: oscillator input divided by 32 (2 MHz max.)
 = 1: oscillator input divided by 16 (1 MHz max.)
 = 2: oscillator input divided by 8 (500 kHz max.)
 = 3: single-pin RC controlled oscillator ($\div 4$)
 = 4: External Schmitt trigger clock input ($\div 4$)
- Option 4: RESET Input
 = 0: load device to V_{CC}
 = 1: Hi-Z Input
- Option 5: L₇ Driver
 = 0: Standard output
 = 1: Open-drain output
 = 2: High current LED direct segment drive output
 = 3: High current TRI-STATE push-pull output
 = 4: Low-current LED direct segment drive output
 = 5: Low-current TRI-STATE push-pull output
- Option 6: L₆ Driver
 same as Option 5
- Option 7: L₅ Driver
 same as Option 5
- Option 8: L₄ Driver
 same as Option 5
- Option 9: IN₁ Input
 = 0: load device to V_{CC}
 = 1: Hi-Z input
- Option 10: IN₂ Input
 same as Option 9
- Option 11: V_{CC} pin
 = 0: Standard V_{CC}
- Option 12: L₃ Driver
 same as Option 5
- Option 13: L₂ Driver
 same as Option 5
- Option 14: L₁ Driver
 same as Option 5
- Option 15: L₀ Driver
 same as Option 5
- Option 16: SI Input
 same as Option 9
- Option 17: SO Driver
 = 0: standard output
 = 1: open-drain output
 = 2: push-pull output
- Option 18: SK Driver
 same as Option 17
- Option 19: IN₀ Input
 same as Option 9
- Option 20: IN₃ Input
 same as Option 9
- Option 21: G₀ I/O Port
 = 0: very-high current standard output
 = 1: very-high current open-drain output
 = 2: high current standard output
 = 3: high current open-drain output
 = 4: standard LSTTL output (fanout = 1)
 = 5: open-drain LSTTL output (fanout = 1)
- Option 22: G₁ I/O Port
 same as Option 21
- Option 23: G₂ I/O Port
 same as Option 21
- Option 24: G₃ I/O Port
 same as Option 21
- Option 25: D₃ Output
 same as Option 21
- Option 26: D₂ Output
 same as Option 21
- Option 27: D₁ Output
 same as Option 21
- Option 28: D₀ Output
 same as Option 21
- Option 29: L Input Levels
 = 0: standard TTL input levels ("0" = 0.8V, "1" = 2.0V)
 = 1: higher voltage input levels
 ("0" = 1.2V, "1" = 3.6V)
- Option 30: IN Input Levels
 same as Option 29
- Option 31: G Input Levels
 same as Option 29
- Option 32: SI Input Levels
 same as Option 29
- Option 33: RESET Input
 = 0: Schmitt trigger input
 = 1: standard TTL input levels
 = 2: higher voltage input levels
- Option 34: CKO Input Levels
 (CKO = input; Option 2 = 2,3)
 same as Option 29
- Option 35: COP Bonding
 = 0: COP420L (28-pin device)
 = 1: COP421L (24-pin device)
 = 2: 28- and 24-pin versions
 = 3: COP422L (20-pin device)
 = 4: 28- and 20-pin versions
 = 5: 24- and 20-pin versions
 = 5: 28-, 24-, and 20-pin versions
- Option 36: Internal Initialization Logic
 = 0: normal operation
 = 1: no internal initialization logic

Option Table

The following EPROM option information is to be sent to National along with the EPROM.

OPTION DATA	
OPTION 1 VALUE =	<u>0</u> IS: GROUND PIN

OPTION 36 VALUE =	_____ IS: INTERNAL INITIALIZATION LOGIC

TEST MODE (Non-Standard Operation)

The SO output has been configured to provide for standard test procedures for the customer-programmed COP420L. With SO forced to logic "1", two test modes are provided, depending upon the value of SI:

- a. RAM and Internal Logic Test Mode (SI = 1)
- b. ROM Test Mode (SI = 0)

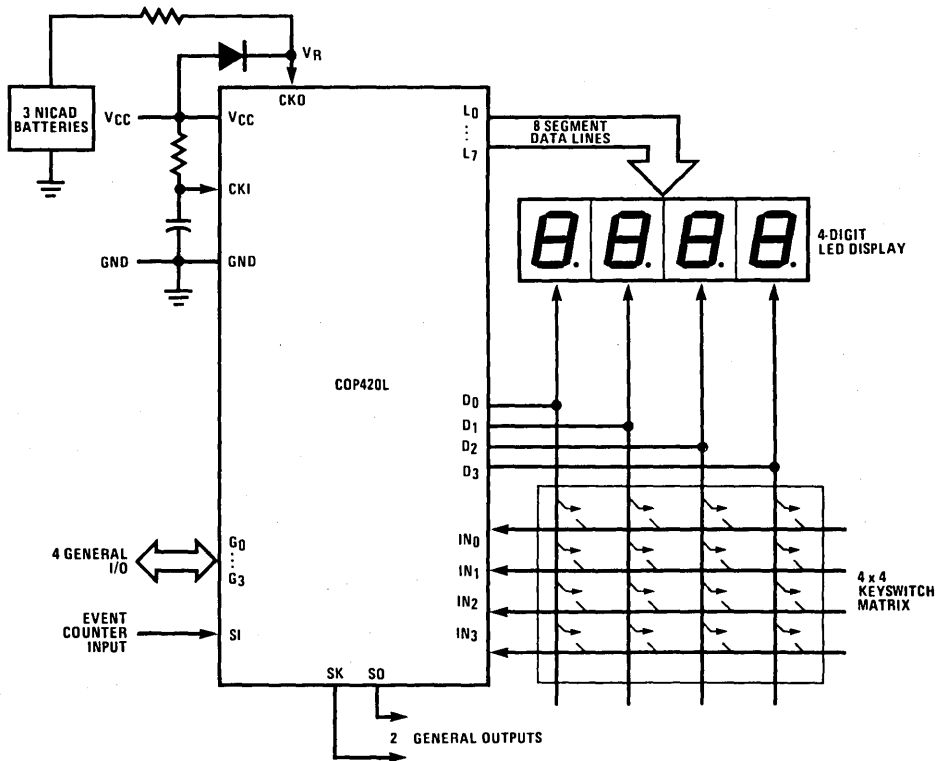

These special test modes should not be employed by the user; they are intended for manufacturing test only.

APPLICATIONS # 1: COP420L General Controller

Figure 9 shows an interconnect diagram for a COP420L used as a general controller. Operation of the system is as follows:

1. The L₇–L₀ outputs are configured as LED Direct Drive outputs, allowing direct connection to the segments of the display.
2. The D₃–D₀ outputs drive the digits of the multiplexed display directly and scan the columns of the 4 x 4 keyboard matrix.
3. The IN₃–IN₀ inputs are used to input the 4 rows of the keyboard matrix. Reading the IN lines in conjunction with the current value of the D outputs allows detection, debouncing, and decoding of any one of the 16 keyswitches.
4. CKI is configured as a single-pin oscillator input allowing system timing to be controlled by a single-pin RC network. CKO is therefore available for use as a general purpose input.
5. SI is selected as the input to a binary counter input. With SIO used as a binary counter, SO and SK can be used as general purpose outputs.
6. The 4 bidirectional G I/O ports (G₃–G₀) are available for use as required by the user's application.

Typical Applications

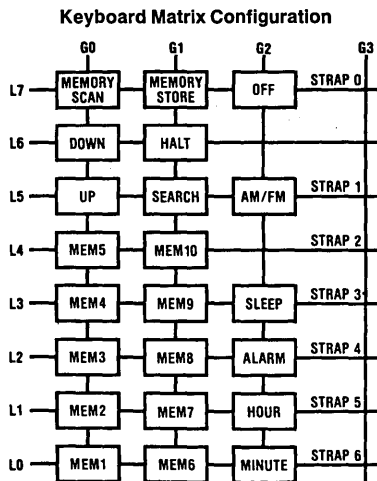

*SO, SI, SK may also be used for Serial I/O

TL/DD/8825-22

FIGURE 9. COP420L Keyboard/Display Interface

APPLICATION #2:

Digitally Tuned Radio Controller and Clock

TL/DD/8825-23

Typical Applications (Continued)

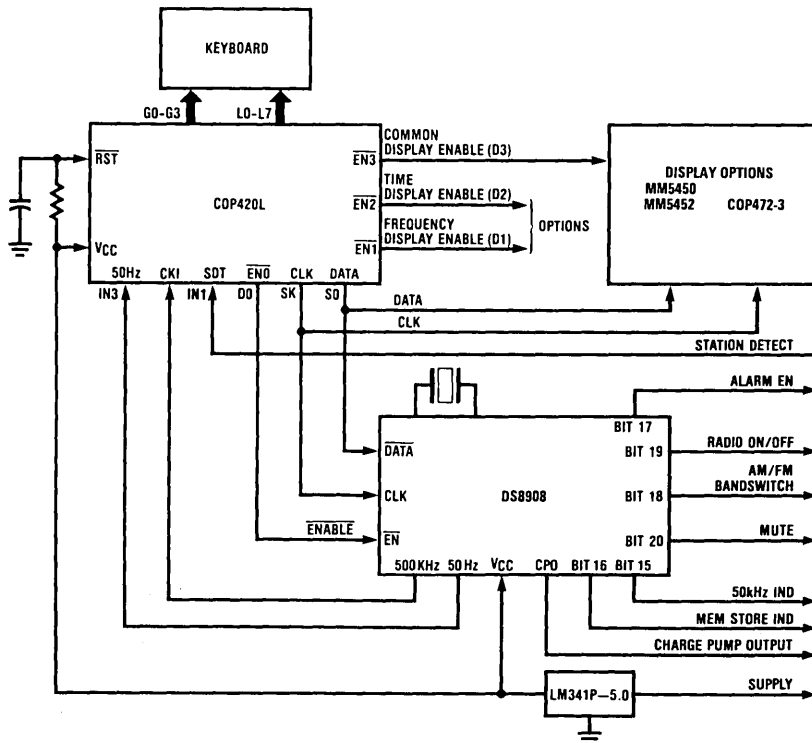

FIGURE 10. Digital Tuning System Block

TL/DD/8825-24

Functional Description

LOGIC I/Os

CKI Input: This input accepts an external 500 kHz signal, divides it by eight and outputs the quotient at the CLK output as the system clock.

RST Input: Schmitt trigger input to clear device upon initialization.

SDT Input: Interrupt input for station detection. The SDT signal is generated by the radio's station detector and used by the COP420L to determine if there is a valid station on the active frequency. The status of the SDT input is only relevant during station searching mode. A high on SDT will temporarily terminate the search mode for eight seconds.

ALM Input: A high on ALM will activate alarm output via slave device at alarm time. A low on the input will disable alarm function.

DATA Output: Push-pull output providing serial data to external devices.

CLK Output: Push-pull output providing system clock at data transmitting time.

50 Hz Input: A normally high input to accept a 50 Hz external time base for real-time calculation.

MOMENTARY KEYS DESCRIPTION

MEM 1–MEM 10: Each memory represents data of a favorite station in a certain band. Depression of one of these

keys will recall the previous stored data and transmit it to the PLL. The PLL will in turn change the radio's receiving frequency as well as the band if necessary. Memory recall keys can also turn on the radio.

UP: This key will manually increment receiving frequency. The first four steps of increment will be for fine tuning a station, after which will be fast slewing meant for manual receive frequency changing.

DOWN: Has the same function as UP key except that frequency is decremented.

MEMORY SCAN: This will start the radio scanning through all ten memories automatically at eight seconds per memory starting from Memory 1. This will also turn on the radio if it was off.

MEMORY STORE: Enables the memory store mode which lasts for three seconds. Depression of any memory key will store the active frequency and band in that memory and disable the store mode. Any function key will also disable the mode to prevent memory data being accidentally destroyed.

HALT: Depression of the HALT key will stop the search and scan functions at current frequency or memory. HALT also turns on the radio during off time and recall frequency display in signal display mode.

SEARCH: Activates station searching in the current band. Search speed is 50 ms per frequency step with wrapping

Functional Description (Continued)

around at end of band. An 8-second stop will take place on reaching a valid station. The HALT key or any function key will terminate the search. Search direction will normally be upwards unless the DOWN key has been depressed prior to the SEARCH key or during the search function in which case search direction will be downwards.

OFF: Turns off the radio or alarm when active.

AM/FM: Radio band switch.

SLEEP: Activates sleep mode, turns on radio on depression and off radio at the end of sleep period. Setting of sleep period is done by depressing the SLEEP and MINUTE key simultaneously.

ALARM: Enables alarm time setting. Depressing the HOUR or MINUTE key and ALARM key simultaneously will set the alarm hour and minute respectively.

HOUR: Sets the hour digits of time-related functions.

MINUTE: Sets the minute digits of time-related functions.

DIODE STRAPS CONNECTIONS

STRAP 0: Controls the on and off of radio. In applications where a toggle type ON/OFF switch is used, momentary OFF key can be omitted; connecting the strap will turn on the radio and vice versa. Must be connected to use momentary OFF key.

STRAP 1, 2: Selects the AM IF options.

STRAP 3: 12/24-hour clock select.

STRAP 4: 3/5 kHz AM step size select.

STRAP 5, 6: FM IF offsets select.

	STRAP 0	STRAP 3	STRAP 4
Connected	Radio ON	12 hour	5 kHz step
Open	Radio OFF	24 hour	3 kHz step

AM/FM IF OPTIONS

AM	STRAP 1	STRAP 2
455 kHz	X	X
460 kHz	X	✓
450 kHz	✓	X
260 kHz	✓	✓
FM	STRAP 5	STRAP 6
10.7 MHz	X	X
10.75 MHz	X	✓
10.65 MHz	✓	X
10.8 MHz	✓	✓

X = No connection.

✓ = Diode inserted.

INDIRECT FEATURES AND OPTIONS

As indicated in *Figure 10*, there are a few options and indirect features provided via the help of a slave device, namely the Phase Lock Loop, DS8906N.

DISPLAY OPTIONS

As mentioned above, the COP420L-HSB is MICROWIRE compatible. Internal circuitry enables it to directly interface with all of National's serial input MICROWIRE compatible display drivers whether they are of a direct drive or multiplex drive format. On *Figure 10* is a list of drivers available for the system. EN1 and EN2 are optional enable outputs meant for a dual display system in which EN3 will not be used. By dual display, it means that one display will be constantly showing time information and the other showing frequency information. Whereas in conventional single display systems, the display shows both time and frequency information in a time-sharing method. The National system provides a time-prioritized display-sharing method. That is, whenever a tuning function is completed, the frequency information will stay on the display for eight seconds then time display will take over. This is achieved by using EN3 for the driver's enable logic.

CONTROL OUTPUTS

Six open collector outputs controlled by the COP420L are provided from DS8906N, the phase lock loop for controlling radio switching circuits.

Radio ON/OFF: A high from this output indicates that the radio should be switched on and vice versa.

AM/FM: Output for controlling the AM/FM bandswitch. A high level output indicates FM and a low indicates the AM band.

MUTE: For muting the audio output when performing any frequency related function. The output will go high prior to the frequency change except when doing fine tuning.

ALARM ENABLE: Active high output for turning on the alarm circuit at alarm time.

50 kHz IND: For driving the 50 kHz indicator in FM band or the LSB in a 5-digit display. Output is active high.

MEM STORE IND: For driving the memory store mode indicator. Output is active high.

TYPICAL IMPLEMENTATION ALTERNATIVES

A full keyboard or any portion of it can be implemented with various applications for features/functions vs. cost/size.

Figure 11 shows two keyboard configurations with 22-key and 11-key keyboards for a desk-top/tuner system or auto-radio system, respectively.

COP424C, COP425C, COP426C, COP324C, COP325C, COP326C and COP444C, COP445C, COP344C, COP345C Single-Chip 1k and 2k CMOS Microcontrollers

General Description

The COP424C, COP425C, COP426C, COP444C and COP445C fully static, Single-Chip CMOS Microcontrollers are members of the COPSTM family, fabricated using double-poly, silicon gate microCMOS technology. These Controller Oriented Processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP424C and COP444C are 28 pin chips. The COP425C and COP445C are 24-pin versions (4 inputs removed) and COP426C is 20-pin version with 15 I/O lines. Standard test procedures and reliable high-density techniques provide the medium to large volume customers with a customized microcontroller at a low end-product cost. These microcontrollers are appropriate choices in many demanding control environments especially those with human interface.

The COP424C is an improved product which replaces the COP420C.

Features

- Lowest power dissipation (50 μ W typical)
- Fully static (can turn off the clock)
- Power saving IDLE state and HALT mode
- 4 μ s instruction time, plus software selectable clocks
- 2k x 8 ROM, 128 x 4 RAM (COP444C/COP445C)
- 1k x 8 ROM, 64 x 4 RAM (COP424C/COP425C/COP426C)
- 23 I/O lines (COP444C and COP424C)
- True vectored interrupt, plus restart
- Three-level subroutine stack
- Single supply operation (2.4V to 5.5V)
- Programmable read/write 8-bit timer/event counter
- Internal binary counter register with MICROWIRE™ serial I/O capability
- General purpose and TRI-STATE® outputs
- LSTTL/CMOS output compatible
- Microbus™ compatible
- Software/hardware compatible with COP400 family
- Extended temperature range devices COP324C/COP325C/COP326C and COP344C/COP345C (-40°C to +85°C)
- Military devices (-55°C to +125°C) to be available

Block Diagram

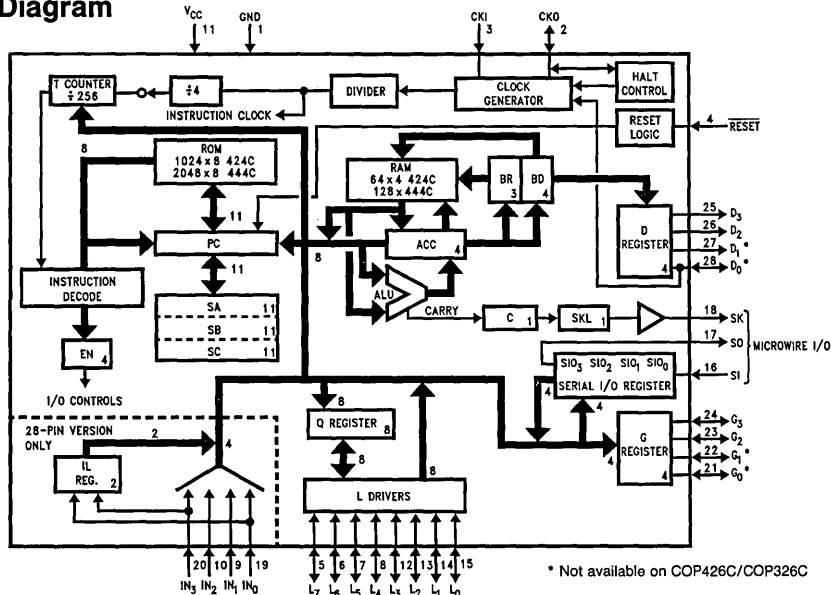

FIGURE 1

COP424C/COP425C/COP426C and COP444C/COP445C**Absolute Maximum Ratings**

Supply Voltage (V_{CC})	6V
Voltage at any Pin	-0.3V to V_{CC} + 0.3V
Total Allowable Source Current	25 mA
Total Allowable Sink Current	25 mA
Operating Temperature Range	0°C to +70°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (soldering, 10 seconds)	300°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics 0°C ≤ T_A ≤ 70°C unless otherwise specified

Note 1: Supply current is measured after running for 2000 cycle times with a square-wave clock on CKI, CKO open, and all other pins pulled up to V_{CC} with 5k resistors. See current drain equation on page 17.

Note 2: The HALT mode will stop CKI from oscillating in the RC and crystal configurations. Test conditions: all inputs tied to V_{CC} , L lines in TRI-STATE mode and tied to ground, all outputs low and tied to ground.

Note 3: When forcing HALT, current is only needed for a short time (approx. 200 ns) to flip the HALT flip-flop.

Note 4: This parameter is only sampled and not 100% tested. Variation due to the device included.

Note 5: Voltage change must be less than 0.5 volts in a 1 ms period.

Note 6: SO output sink current must be limited to keep V_{OL} less than $0.2V_{CC}$ when part is running in order to prevent entering test mode.

Pin	Description
L7-L0	8-bit bidirectional port with TRI-STATE
G3-G0	4-bit bidirectional I/O port
D3-D0	4-bit output port
IN3-IN0	4-bit input port (28-pin package only)
SI	Serial input or counter input
SO	Serial or general purpose output

Pin	Description
SK	Logic controlled clock output
CKI	Chip oscillator input
CKO	Oscillator output, HALT I/O port or general purpose input
RESET	Reset input
VCC	Most positive power supply
GND	Ground

Functional Description

The internal architecture is shown in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1", when a bit is reset, it is a logic "0".

For ease of reading only the COP424C/425C/COP426C/444C/445C are referenced; however, all such references apply equally to COP324C/325C/COP326C/344C/345C.

PROGRAM MEMORY

Program Memory consists of ROM, 1024 bytes for the COP424C/425C/426C and 2048 bytes for the COP444C/445C. These bytes of ROM may be program instructions, constants or ROM addressing data.

ROM addressing is accomplished by a 11-bit PC register which selects one of the 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 11-bit binary count value.

Three levels of subroutine nesting are implemented by a three level deep stack. Each subroutine call or interrupt pushes the next PC address into the stack. Each return pops the stack back into the PC register.

DATA MEMORY

Data memory consists of a 512-bit RAM for the COP444C/445C, organized as 8 data registers of 16×4 -bit digits. RAM addressing is implemented by a 7-bit B register whose upper 3 bits (Br) select 1 of 8 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register.

Data memory consists of a 256-bit RAM for the COP424C/425C/426C, organized as 4 data registers of 16×4 -bits digits. The B register is 6 bits long. Upper 2 bits (Br) select 1 of 4 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) are usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or T counter or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instructions based upon the immediate operand field of these instructions.

The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

INTERNAL LOGIC

The processor contains its own 4-bit A register (accumulator) which is the source and destination register for most I/O, arithmetic, logic, and data memory access operations. It can also be used to load the Br and Bd portions of the B register, to load and input 4 bits of the 8-bit Q latch or T counter, to input 4 bits of L I/O ports data, to input 4-bit G, or IN ports, and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions, storing the results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register in conjunction with the XAS instruction and the EN register, also serves to control the SK output.

The 8-bit T counter is a binary up counter which can be loaded to and from M and A using CAMT and CTMA instructions. When the T counter overflows, an overflow flag will be set (see SKT and IT instructions below). The T counter is cleared on reset. A functional block diagram of the timer/counter is illustrated in *Figure 10a*.

Four general-purpose inputs, IN3-IN0, are provided. IN1, IN2 and IN3 may be selected, by a mask-programmable option as Read Strobe, Chip Select, and Write Strobe inputs, respectively, for use in Microbus application.

The D register provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of Bd. In the dual clock mode, D0 latch controls the clock selection (see dual oscillator below).

The G register contents are outputs to a 4-bit general-purpose bidirectional I/O port. G0 may be mask-programmed as an output for Microbus applications.

The Q register is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are outputted to the L I/O ports when the L drivers are enabled under program control. With the Microbus option selected, Q can also be loaded with the 8-bit contents of the L I/O ports upon the occurrence of a write strobe from the host CPU.

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O port. Also, the contents of L may be read directly into A and M. As explained above, the Microbus option allows L I/O port data to be latched into the Q register.

Functional Description (Continued)

The SIO register functions as a 4-bit serial-in/serial-out shift register for MICROWIRE I/O and COPS peripherals, or as a binary counter (depending on the contents of the EN register). Its contents can be exchanged with A.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK outputs SKL ANDed with the clock.

EN is an internal 4-bit register loaded by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register:

- 0. The least significant bit of the enable register, EN0, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN0 set, SIO is an asynchronous binary counter, decrementing its value by one upon

each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output equals the value of EN3. With EN0 reset, SIO is a serial shift register left shifting 1 bit each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. The SK outputs SKL ANDed with the instruction cycle clock.

- 1. With EN1 set, interrupt is enabled. Immediately following an interrupt, EN1 is reset to disable further interrupts.
- 2. With EN2 set, the L drivers are enabled to output the data in Q to the L I/O port. Resetting EN2 disables the L drivers, placing the L I/O port in a high-impedance input state.

FIGURE 3. Input/Output Timing Diagrams (divide by 8 mode)

FIGURE 4. Microbus Read Operation Timing

FIGURE 5. Microbus Write Operation Timing

Functional Description (Continued)

3. EN3, in conjunction with EN0, affects the SO output. With EN0 set (binary counter option selected) SO will output the value loaded into EN3. With EN0 reset (serial shift register option selected), setting EN3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN3 with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains set to "0".

INTERRUPT

The following features are associated with interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- a. The interrupt, once recognized as explained below, pushes the next sequential program counter address (PC+1) onto the stack. Any previous contents at the bottom of the stack are lost. The program counter is set to hex address 0FF (the last word of page 3) and EN1 is reset.
- b. An interrupt will be recognized only on the following conditions:
 1. EN1 has been set.
 2. A low-going pulse ("1" to "0") at least two instruction cycles wide has occurred on the IN₁ input.
 3. A currently executing instruction has been completed.
 4. All successive transfer of control instructions and successive LBIs have been completed (e.g. if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed).
- c. Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon popping of the stack. For example, if an interrupt occurs during the execution of ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at hex address 0FF. At the end of the interrupt routine, a RET instruction is executed to pop the stack and return program control to the instruction following the original ASC. At this time, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines should not be nested within the interrupt service routine, since their popping of the stack will enable any previously saved main program skips, interfering with the orderly execution of the interrupt routine.

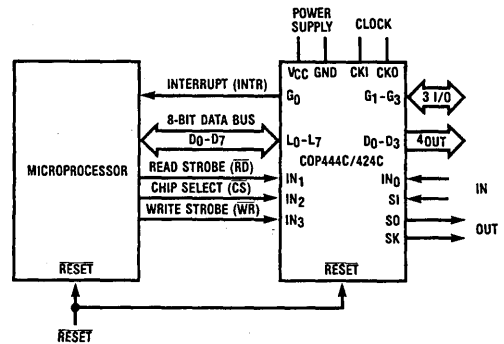

d. The instruction at hex address 0FF must be a NOP.

e. An LEI instruction may be put immediately before the RET instruction to re-enable interrupts.

MICROBUS INTERFACE

The COP444C/424C has an option which allows it to be used as a peripheral microprocessor, inputting and outputting data from and to a host microprocessor (μP). IN₁, IN₂ and IN₃ general purpose inputs become Microbus compatible read-strobe, chip-select, and write-strobe lines, respectively. IN₁ becomes \overline{RD} — a logic "0" on this input will cause Q latch data to be enabled to the L ports for input to the uP. IN₂ becomes \overline{CS} — a logic "0" on this line selects the COP444C/424C as the uP peripheral device by enabling the operation of the \overline{RD} and \overline{WR} lines and allows for the selection of one of several peripheral components. IN₃ becomes \overline{WR} — a logic "0" on this line will write bus data from the L ports to the Q latches for input to the COP444C/424C. G₀ becomes INTR a "ready" output, reset by a write pulse from the uP on the \overline{WR} line, providing the "handshaking" capability necessary for asynchronous data transfer between the host CPU and the COP444C/424C.

This option has been designed for compatibility with National's Microbus — a standard interconnect system for 8-bit parallel data transfer between MOS/LSI CPUs and interfacing devices. (See Microbus National Publication.) The functioning and timing relationships between the signal lines affected by this option are as specified for the Microbus interface, and are given in the AC electrical characteristics and shown in the timing diagrams (Figures 4 and 5). Connection of the COP444C/424C to the Microbus is shown in Figure 6.

TL/DD/5259-7

FIGURE 6. Microbus Option Interconnect

TABLE I. Enable Register Modes — Bits EN0 and EN3

EN0	EN3	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = clock If SKL = 0, SK = 0
0	1	Shift Register	Input to Shift Register	Serial out	If SKL = 1, SK = clock If SKL = 0, SK = 0
1	0	Binary Counter	Input to Counter	0	SK = SKL
1	1	Binary Counter	Input to Counter	1	SK = SKL

Functional Description (Continued)

INITIALIZATION

The internal reset logic will initialize the device upon power-up if the power supply rise time is less than 1 ms and if the operating frequency at CKI is greater than 32 kHz, otherwise the external RC network shown in *Figure 7* must be connected to the **RESET** pin (the conditions in *Figure 7* must be met). The **RESET** pin is configured as a Schmitt trigger input. If not used, it should be connected to V_{CC} . Initialization will occur whenever a logic "0" is applied to the **RESET** input, providing it stays low for at least three instruction cycle times.

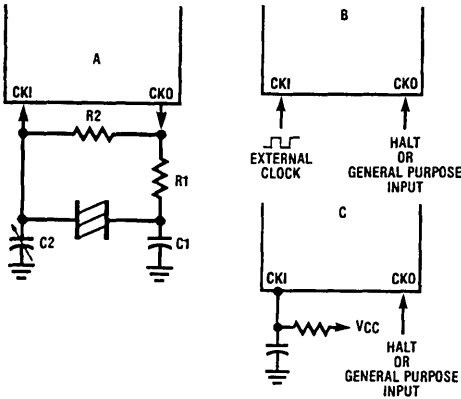

Note: If CKI clock is less than 32 kHz, the internal reset logic (option #29 = 1) MUST be disabled and the external RC circuit must be used.

TL/DD/5259-8

FIGURE 7. Power-Up Circuit

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, IL, T and G registers are cleared. The SKL latch is set, thus enabling SK as a clock output. Data Memory (RAM) is not cleared upon initialization. The first instruction at address 0 must be a CLRA (clear A register).

TL/DD/5259-9

Crystal or Resonator

Crystal Value	Component Values			
	R1	R2	C1(pF)	C2(pF)
32 kHz	220k	20M	30	6-36
455 kHz	5k	10M	80	40
2.096 MHz	2k	1M	30	6-36
4.0 MHz	1k	1M	30	6-36

RC Controlled Oscillator ($\pm 5\% R, \pm 5\% C$)

R	C	Cycle Time	V_{CC}
30k	82 pF	5-11 μ s	$\geq 4.5V$
60k	100 pF	12-24 μ s	2.4-4.5V

Note: $15k \leq R \leq 150k$
 $50 \text{ pF} \leq C \leq 150 \text{ pF}$

FIGURE 8. Oscillator Component Values

TIMER

The timer can be operated as a time-base counter.

The instruction cycle frequency generated from CKI passes through a 2-bit divide-by-4 prescaler. The output of this prescaler increments the 8-bit T counter thus providing a 10-bit timer. The pre-scaler is cleared during execution of a CAMT instruction and on reset.

For example, using a 4 MHz crystal with a divide-by-16 option, the instruction cycle frequency of 250 kHz increments the 10-bit timer every 4 μ s. By presetting the counter and detecting overflow, accurate timeouts between 16 μ s (4 counts) and 4.096 ms (1024 counts) are possible. Longer timeouts can be achieved by accumulating, under software control, multiple overflows.

HALT MODE

The COP444C/445C/424C/425C/426C is a FULLY STAT-IC circuit; therefore, the user may stop the system oscillator at any time to halt the chip. The chip may also be halted by the HALT instruction or by forcing CKO high when it is mask-programmed as an HALT I/O port. Once in the HALT mode, the internal circuitry does not receive any clock signal and is therefore frozen in the exact state it was in when halted. All information is retained until continuing. The chip may be awakened by one of two different methods:

- Continue function: by forcing CKO low, if it mask-programmed as an HALT I/O port, the system clock is re-enabled and the circuit continues to operate from the point where it was stopped.
- Restart: by forcing the **RESET** pin low (see Initialization).

Functional Description (Continued)

The HALT mode is the minimum power dissipation state.

Note: If the user has selected dual-clock with D0 as external oscillator (option 30=2) AND the COP444C/424C is running with the D0 clock, the HALT mode — either hardware or software — will NOT be entered. Thus, the user should switch to the CKI clock to HALT. Alternatively, the user may stop the D0 clock to minimize power.

CKO PIN OPTIONS

a. Two-pin oscillator — (Crystal). See *Figure 9A*.

In a crystal controlled oscillator system, CKO is used as an output to the crystal network. The HALT mode may be entered by program control (HALT instruction) which forces CKO high, thus inhibiting the crystal network. The circuit can be awakened only by forcing the RESET pin to a logic "0" (restart).

b. One-pin oscillator — (RC or external). See *Figure 9B*.

If a one-pin oscillator system is chosen, two options are available for CKO:

- CKO can be selected as the HALT I/O port. In that case, it is an I/O flip-flop which is an indicator of the HALT status. An external signal can over-ride this pin to start and stop the chip. By forcing a high level to CKO, the chip will stop as soon as CKI is high and CKO output will stay high to keep the chip stopped if the external driver returns to high impedance state. By forcing a low level to CKO, the chip will continue and CKO will stay low.
- As another option, CKO can be a general purpose input, read into bit 2 of A (accumulator) upon execution of an INIL instruction.

OSCILLATOR OPTIONS

There are four basic clock oscillator configurations available as shown by *Figure 8*.

- Crystal Controlled Oscillator. CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency optionally divided by 4, 8 or 16.
- External Oscillator. The external frequency is optionally divided by 4, 8 or 16 to give the instruction cycle time. CKO is the HALT I/O port or a general purpose input.

c. RC Controlled Oscillator. CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is the HALT I/O port or a general purpose input.

d. Dual oscillator. By selecting the dual clock option, pin D0 is now a single pin oscillator input. Two configurations are available: RC controlled Schmitt trigger oscillator or external oscillator.

The user may software select between the D0 oscillator (in that case, the instruction cycle time equals the D0 oscillation frequency divided by 4) by setting the D0 latch high or the CKI (CKO) oscillator by resetting D0 latch low. Note that even in dual clock mode, the counter, if mask-programmed as a time-base counter, is always connected to the CKI oscillator.

For example, the user may connect up to a 1 MHz RC circuit to D0 for faster processing and a 32 kHz watch crystal to CKI and CKO for minimum current drain and time keeping.

Note: CTMA instruction is not allowed when chip is running from D0 clock.

Figures 10A and 10B show the clock and timer diagrams with and without Dual clock.

COP445C AND COP425C 24-PIN PACKAGE OPTION

If the COP444C/424C is bonded in a 24-pin package, it becomes the COP445C/425C, illustrated in *Figure 2*, Connection diagrams. Note that the COP445C/425C does not contain the four general purpose IN inputs (IN3–IN0). Use of this option precludes, of course, use of the IN options, interrupt feature, external event counter feature, and the Microbus option which uses IN1–IN3. All other options are available for the COP445C/425C.

Note: If user selects the 24-pin package, options 9, 10, 19 and 20 must be selected as a "0" (load to V_{CC} on the IN inputs). See option list.

COP426C 20-PIN PACKAGE OPTION

If the COP425C is bonded as 20-pin device it becomes the COP426C. Note that the COP426C contains all the COP425C pins except D₀, D₁, G₀, and G₁.

Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operation symbols used in the instruction set table.

TABLE II. Instruction Set Table Symbols

Symbol	Definition
Internal Architecture Symbols	
A	4-bit accumulator
B	7-bit RAM address register (6-bit for COP424C)
Br	Upper 3 bits of B (register address) (2-bit for COP424C)
Bd	Lower 4 bits of B (digit address)
C	1-bit carry register
D	4-bit data output port
EN	4-bit enable register
G	4-bit general purpose I/O port
IL	two 1-bit (IN0 and IN3) latches
IN	4-bit input port
L	8-bit TRI-STATE I/O port
M	4-bit contents of RAM addressed by B
PC	11-bit ROM address program counter
Q	8-bit latch for L port
SA,SB,SC	11-bit 3-level subroutine stack
SIO	4-bit shift register and counter
SK	Logic-controlled clock output
SKL	1-bit latch for SK output
T	8-bit timer

Table III provides the mnemonic, operand, machine code data flow, skip conditions and description of each instruction.

Instruction Operand Symbols

d	4-bit operand field, 0–15 binary (RAM digit select)
r	3(2)-bit operand field, 0–7(3) binary (RAM register select)
a	11-bit operand field, 0–2047 (1023)
y	4-bit operand field, 0–15 (immediate data)
RAM(x)	RAM addressed by variable x
ROM(x)	ROM addressed by variable x

Operational Symbols

+	Plus
–	Minus
→	Replaces
↔	Is exchanged with
=	Is equal to
\bar{A}	One's complement of A
⊕	Exclusive-or
:	Range of values

		5-	0101 y			
OMG		33	0011 0011	RAM(B) → G	None	Output RAM to G Ports
		3A	0011 1010			
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 3)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: The ININ instruction is not available on the 24-pin packages since these devices do not contain the IN inputs.

Note 3: For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.

Note 4: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 5: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 6: LBI is a single-byte instruction if d = 0, 9, 10, 11, 12, 13, 14, or 15. The machine code for the lower 4 bits equals the binary value of the "d" data minus 7, e.g., to load the lower four bits of B(Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 7: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Note 8: For 2K ROM devices, A ↔ Br (0 → A3). For 1K ROM devices, A ↔ Br (0,0 → A3, A2).

Note 9: Do not use CTMA instruction when dual-clock option is selected and part is running from D₀ clocks.

Description of Selected Instructions

XAS INSTRUCTION

XAS (Exchange A with SIO) copies C to the SKL latch and exchanges the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. If SIO is selected as a shift register, an XAS instruction can be performed once every 4 instruction cycles to effect a continuous data stream.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 11-bit word PC10:PC8,A,M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC+1 → SA → SB → SC) and replaces the least significant 8 bits of the PC as follows: A → PC(7:4), RAM(B) → PC(3:0), leaving PC(10), PC(9) and PC(8) unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SC → SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SB → SC, the previous contents of SC are lost.

Note: LQID uses 2 instruction cycles if executed, one if skipped.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the contents of ROM addressed by the 11-bit word, PC10:8,A,M. PC10,PC9 and PC8 are not affected by JID.

Note: JID uses 2 instruction cycles if executed, one if skipped.

SKT INSTRUCTION

The SKT (Skip On Timer) instruction tests the state of the T counter overflow latch (see internal logic, above), executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction allow the processor to generate its own time-base for real-time processing, rather than relying on an external input signal.

Note: If the most significant bit of the T counter is a 1 when a CAMT instruction loads the counter, the overflow flag will be set. The following sample of codes should be used when loading the counter:

```
CAMT ; load T counter
SKT  ; skip if overflow flag is set and reset it
NOP
```

IT INSTRUCTION

The IT (idle till timer) instruction halts the processor and puts it in an idle state until the time-base counter overflows. This idle state reduces current drain since all logic (except the oscillator and time base counter) is stopped.

INIL INSTRUCTION

INIL (Input IL Latches to A) inputs 2 latches, IL3 and IL0, CKO and 0 into A. The IL3 and IL0 latches are set if a low-going pulse ("1" to "0") has occurred on the IN3 and IN0 inputs since the last INIL instruction, provided the input pulse stays low for at least two instruction cycles. Execution of an INIL inputs IL3 and IL0 into A3 and A0 respectively,

and resets these latches to allow them to respond to subsequent low-going pulses on the IN3 and IN0 lines. If CKO is mask programmed as a general purpose input, an INIL will input the state of CKO into A2. If CKO has not been so programmed, a "1" will be placed in A2. A0 is input into A1. IL latches are cleared on reset. IL latches are not available on the COP445C/425C, and COP426C.

INSTRUCTION SET NOTES

- The first word of a program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, they are still fetched from the program memory. Thus program paths take the same number of cycles whether instructions are skipped or executed except for JID, and LQID.
- The ROM is organized into pages of 64 words each. The Program Counter is a 11-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID, or LQID is the last word of a page, it operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a JID or LQID located in the last word of every fourth page (i.e. hex address 0FF, 1FF, 2FF, 3FF, 4FF, etc.) will access data in the next group of four pages.

Note: The COP424C/425C/426C needs only 10 bits to address its ROM. Therefore, the eleventh bit (P10) is ignored.

Power Dissipation

The lowest power drain is when the clock is stopped. As the frequency increases so does current. Current is also lower at lower operating voltages. Therefore, the user should run at the lowest speed and voltage that his application will allow. The user should take care that all pins swing to full supply levels to insure that outputs are not loaded down and that inputs are not at some intermediate level which may draw current. Any input with a slow rise or fall time will draw additional current. A crystal or resonator generated clock input will draw additional current. An R/C oscillator will draw even more current since the input is a slow rising signal.

If using an external squarewave oscillator, the following equation can be used to calculate operating current drain.

$$I_{CO} = I_Q + V \times 40 \times F_i + V \times 1400 \times F_i / D_V$$

where I_{CO} = chip operating current drain in microamps
 quiescent leakage current (from curve)
 CKI frequency in MegaHertz
 chip V_{CC} in volts
 divide by option selected

For example at 5 volts V_{CC} and 400 kHz (divide by 4)

$$I_{CO} = 20 + 5 \times 40 \times 0.4 + 5 \times 1400 \times 0.4 / 4$$

$$I_{CO} = 20 + 80 + 700 = 800 \mu A$$

At 2.4 volts V_{CC} and 30 kHz (divide by 4)

$$I_{CO} = 6 + 2.4 \times 40 \times 0.03 + 2.4 \times 1400 \times 0.03 / 4$$

$$I_{CO} = 6 + 2.88 + 25.2 = 34.08 \mu A$$

Power Dissipation (Continued)

If an IT instruction is executed, the chip goes into the IDLE mode until the timer overflows. In IDLE mode, the current drain can be calculated from the following equation:

$$I_{ci} = I_Q + V \times 40 \times F_i$$

For example, at 5 volts V_{CC} and 400 kHz

$$I_{ci} = 20 + 5 \times 40 \times 0.4 = 100 \mu A$$

The total average current will then be the weighted average of the operating current and the idle current:

$$I_{ta} = I_{CO} \times \frac{T_o}{T_o + T_i} + I_{ci} \times \frac{T_i}{T_o + T_i}$$

where: I_{ta} = total average current

I_{CO} = operating current

I_{ci} = idle current

T_o = operating time

T_i = idle time

I/O OPTIONS

Outputs have the following optional configurations, illustrated in Figure 11:

- a. Standard — A CMOS push-pull buffer with an N-channel device to ground in conjunction with a P-channel device to V_{CC} , compatible with CMOS and LSTTL.
- b. Low Current — This is the same configuration as a. above except that the sourcing current is much less.

- c. Open Drain — An N-channel device to ground only, allowing external pull-up as required by the user's application.
- d. Standard TRI-STATE L Output — A CMOS output buffer similar to a. which may be disabled by program control.
- e. Low-Current TRI-STATE L Output — This is the same as d. above except that the sourcing current is much less.
- f. Open-Drain TRI-STATE L Output — This has the N-channel device to ground only.

All inputs have the following options:

- g. Input with on chip load device to V_{CC} .
- h. Hi-Z input which must be driven by the users logic.

When using either the G or L I/O ports as inputs, a pull-up device is necessary. This can be an external device or the following alternative is available: Select the low-current output option. Now, by setting the output registers to a logic "1" level, the P-channel devices will act as the pull-up load. Note that when using the L ports in this fashion the Q registers must be set to a logic "1" level and the L drivers MUST BE ENABLED by an LEI instruction (see description above).

All output drivers use one or more of three common devices numbered 1 to 3. Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in Figure 12 for each of these devices to allow the designer to effectively use these I/O configurations.

Option List

The COP444C/445C/424C/425C/COP426C mask-programmable options are assigned numbers which correspond with the COP444C/424C pins.

The following is a list of options. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

PLEASE FILL OUT THE OPTION TABLE on the next page. Xerox the option data and send it in with your disk or EPROM.

Option 1 = 0: Ground Pin — no options available

Option 2: CKO Pin

- = 0: clock generator output to crystal/resonator
- = 1: HALT I/O port
- = 2: general purpose input with load device to V_{CC}
- = 3: general purpose input, high-Z

Option 3: CKI input

- = 0: Crystal controlled oscillator input divide by 4
- = 1: Crystal controlled oscillator input divide by 8
- = 2: Crystal controlled oscillator input divide by 16
- = 4: Single-pin RC controlled oscillator (divide by 4)
- = 5: External oscillator input divide by 4
- = 6: External oscillator input divide by 8
- = 7: External oscillator input divide by 16

Option 4: $\overline{\text{RESET}}$ input

- = 0: load device to V_{CC}
- = 1: Hi-Z input

Option 5: L7 Driver

- = 0: Standard TRI-STATE push-pull output
- = 1: Low-current TRI-STATE push-pull output
- = 2: Open-drain TRI-STATE output

Option 6: L6 Driver — (same as option 5)

Option 7: L5 Driver — (same as option 5)

Option 8: L4 Driver — (same as option 5)

Option 9: IN1 input

- = 0: load device to V_{CC}
- = 1: Hi-Z input

Option 10: IN2 input — (same as option 9)

Option 11 = 0: V_{CC} Pin — no option available

Option 12: L3 Driver — (same as option 5)

Option 13: L2 Driver — (same as option 5)

Option 14: L1 Driver — (same as option 5)

Option 15: L0 Driver — (same as option 5)

Option 16: SI input — (same as option 9)

Option 17: SO Driver

- = 0: Standard push-pull output
- = 1: Low-current push-pull output
- = 2: Open-drain output

Option List (Continued)

Option 18: SK Driver — (same as option 17)

Option 19: IN0 Input — (same as option 9)

Option 20: IN3 Input — (same as option 9)

Option 21: G0 I/O Port — (same as option 17)

Option 22: G1 I/O Port — (same as option 17)

Option 23: G2 I/O Port — (same as option 17)

Option 24: G3 I/O Port — (same as option 17)

Option 25: D3 Output — (same as option 17)

Option 26: D2 Output — (same as option 17)

Option 27: D1 Output — (same as option 17)

Option 28: D0 Output — (same as option 17)

Option 29: Internal Initialization Logic

= 0: Normal operation

= 1: No internal initialization logic

Option 30: Dual Clock

= 0: Normal operation

= 1: Dual Clock. D0 RC oscillator } (opt. #28 must = 2)

= 2: Dual Clock. D0 ext. clock input }

Option 31: Timer

= 0: No Option Available

Option 32: Microbus

= 0: Normal

= 1: Microbus (opt. #31 must = 0)

Option 33: COP bonding

(1K and 2K Microcontroller)

= 0: 28-pin package

= 1: 24-pin package

= 2: Same die purchased in both
24 and 28 pin version.

(1K Microcontroller only)

= 3: 20-pin package

= 4: 28- and 20-pin package

= 5: 24- and 20-pin package

= 6: 28-, 24- and 20-pin package

Note:—if opt. #33 = 1 or 2 then opt. #9, 10, 19, 20 and 32 must = 0—if opt. #33 = 3, 4, 5 or 6 then opt. #9, 10, 19, 20, 21, 22, 30 and 32 must = 0.

COP444L/COP445L/COP344L/COP345L Single-Chip N-Channel Microcontrollers

General Description

The COP444L, COP445L, COP344L, and COP345L Single-Chip N-Channel Microcontrollers are members of the COPSM family, fabricated using N-channel, silicon gate MOS technology. These controller oriented processors are complete microcomputers containing all system timing, internal logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include single supply operation, a variety of output configuration options, with an instruction set, internal architecture and I/O scheme designed to facilitate keyboard input, display output and BCD data manipulation. The COP445L is identical to the COP444L, but with 19 I/O lines instead of 23. They are an appropriate choice for use in numerous human interface control environments. Standard test procedures and reliable high-density fabrication techniques provide the medium to large volume customers with a customized controller oriented processor at a low end-product cost.

The COP344L and COP345L are exact functional equivalents, but extended temperature range versions of the COP444L and COP445L respectively.

Features

- Low cost
- Powerful instruction set
- 2k x 8 ROM, 128 x 4 RAM
- 23 I/O lines (COP444L)
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 15 μ s instruction time
- Single supply operation (4.5–6.3V)
- Low current drain (11 mA max.)
- Internal time-base counter for real-time processing
- Internal binary counter register with MICROWIRESM serial I/O capability
- General purpose and TRI-STATE[®] outputs
- LSTTL/CMOS compatible in and out
- Direct drive of LED digit and segment lines
- Software/hardware compatible with other members of COP400 family
- Extended temperature range devices
COP344L/COP345L (–40°C to +85°C)

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at Any Pin Relative to GND	-0.5V to +10V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	-65°C to +150°C
Lead Temperature (Soldering, 10 seconds)	300°C
Power Dissipation	0.75 Watt at 25°C 0.4 Watt at 70°C

Total Source Current	120 mA
Total Sink current	120 mA

Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$, $4.5\text{V} \leq V_{CC} \leq 6.3\text{V}$ unless otherwise noted.

Parameter	Conditions	Min	Max	Units
Standard Operating Voltage (V_{CC})		4.5	6.3	V
Power Supply Ripple (Notes 1, 4)	Peak to Peak		0.5	V
Operating Supply Current	All Inputs and Outputs Open		13	mA
Input Voltage Levels				
CKI Input Levels				
Crystal Input ($\div 32$, $\div 16$, $\div 8$)				
Logic High (V_{IH})	$V_{CC} = \text{Max.}$	3.0		V
Logic High (V_{IH})	$V_{CC} = 5\text{V} \pm 5\%$	2.0	0.4	V
Logic Low (V_{IL})		-0.3		V
Schmitt Trigger Input ($\div 4$)				
Logic High (V_{IH})		$0.7 V_{CC}$		V
Logic Low (V_{IL})		-0.3	0.6	V
RESET Input Levels	Schmitt Trigger Input			
Logic High		$0.7 V_{CC}$		V
Logic Low		-0.3	0.6	V
SO Input Level (Test Mode)	(Note 3)	2.0	2.5	V
All Other Inputs				
Logic High	$V_{CC} = \text{Max.}$	3.0		V
Logic High	With TTL Trip Level Options	2.0		V
Logic Low	Selected, $V_{CC} = 5\text{V} \pm 10\%$	-0.3	0.8	V
Logic High	With High Trip Level Options	3.6		V
Logic Low	Selected	-0.3	1.2	V
Input Capacitance (Note 4)			7	pF
Hi-Z Input Leakage		-1	+1	μA
Output Voltage Levels				
LSTTL Operation	$V_{CC} = 5\text{V} \pm 5\%$			
Logic High (V_{OH})	$I_{OH} = -25 \mu\text{A}$	2.7		V
Logic Low (V_{OL})	$I_{OL} = 0.36 \text{ mA}$		0.4	V
CMOS Operation (Note 2)				
Logic High	$I_{OH} = -10 \mu\text{A}$	$V_{CC} - 1$		V
Logic Low	$I_{OL} = +10 \mu\text{A}$		0.2	V

Note 1: V_{CC} voltage change must be less than 0.5V in a 1 ms period to maintain proper operation.

Note 2: TRI-STATE and LED configurations are excluded.

Note 3: SO output "0" level must be less than 0.6V for normal operation.

Note 4: This parameter is only sampled and not 100% tested. Variation due to the device included.

Functional Description

A block diagram of the COP444L is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2 volts). When a bit is reset, it is a logic "0" (less than 0.8 volts).

All functional references to the COP444L/COP445L also apply to the COP344L/COP345L.

PROGRAM MEMORY

Program Memory consists of a 2048 byte ROM. As can be seen by an examination of the COP444L/445L instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID, and LQID instructions, ROM must often be thought of as being organized into 32 pages of 64 words each.

ROM addressing is accomplished by a 11-bit PC register. Its binary value selects one of the 2048 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 11-bit binary count value. Three levels of subroutine nesting are implemented by the 11-bit subroutine save registers, SA, SB, and SC, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 512-bit RAM, organized as 8 data registers of 16 4-bit digits. RAM addressing is implemented by a 7-bit B register whose upper 3 bits (Br) select 1 of 8 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instructions based upon the 7-bit contents of the operand field of these instructions. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Br and Bd portions of the B register, to load and input 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register descriptor, below.)

Four general-purpose inputs, IN₃–IN₀, are provided.

The D register provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of Bd. The D outputs can be directly connected to the digits of a multiplexed LED display.

The G register contents are outputs to 4 general-purpose bidirectional I/O ports. G I/O ports can be directly connected to the digits of a multiplexed LED display.

The Q register is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M. L I/O ports can be directly connected to the segments of a multiplexed LED display (using the LED Direct Drive output configuration option) with Q data being outputted to the Sa–Sg and decimal point segments of the display.

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK outputs SKL ANDed with the clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN₃–EN₀).

1. The least significant bit of the enable register, EN₀, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.
2. With EN₁ set the IN₁ input is enabled as an interrupt input. Immediately following an interrupt, EN₁ is reset to disable further interrupts.
3. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN₂ disables the L drivers, placing the L I/O ports in a high-impedance input state.
4. EN₃, in conjunction with EN₀, affects the SO output. With EN₀ set (binary counter option selected) SO will output the value loaded into EN₃. With EN₀ reset (serial shift register option selected), setting EN₃ enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN₃ with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0". The table below provides a summary of the modes associated with EN₃ and EN₀.

Functional Description (Continued)

Enable Register Modes—Bits EN₃ and EN₀

EN ₃	EN ₀	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = CLOCK If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = CLOCK If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

INTERRUPT

The following features are associated with the IN₁ interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- The interrupt, once acknowledged as explained below, pushes the next sequential program counter address (PC+1) onto the stack, pushing in turn the contents of the other subroutine-save registers to the next lower level (PC + 1 → SA → SB → SC). Any previous contents of SC are lost. The program counter is set to hex address 0FF (the last word of page 3) and EN₁ is reset.
- An interrupt will be acknowledged only after the following conditions are met:
 - EN₁ has been set.
 - A low-going pulse ("1" to "0") at least two instruction cycles wide occurs on the IN₁ input.
 - A currently executing instruction has been completed
 - All successive transfer of control instructions and successive LBIs have been completed (e.g., if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed.
- Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon popping of the stack. For example, if an interrupt occurs during the execution of ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at hex address 0FF. At the end of the interrupt routine, a RET instruction is executed to "pop" the stack and return program control to the instruction following the original ASC. *At this time*, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines and LQID instructions should not be nested within the interrupt service routine, since their popping the stack will enable any previously saved main program skips, interfering with the orderly execution of the interrupt routine.
- The first instruction of the interrupt routine at hex address 0FF must be a NOP.
- A LEI instruction can be put immediately before the RET to re-enable interrupts.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μs. If the power supply rise time is greater than 1 ms, the user use provide an external RC network and diode to the RESET pin as shown below. If the RC network is not used, the RESET pin must be pulled up to V_{CC} either by the internal load or by an external resistor (≥40 kΩ) to V_{CC}. The RESET pin is configured as a Schmitt trigger input. Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

TL/DD/6928-6

RC ≥ 5 x Power Supply Rise Time (R ≥ 40k)

Power-Up Clear Circuit

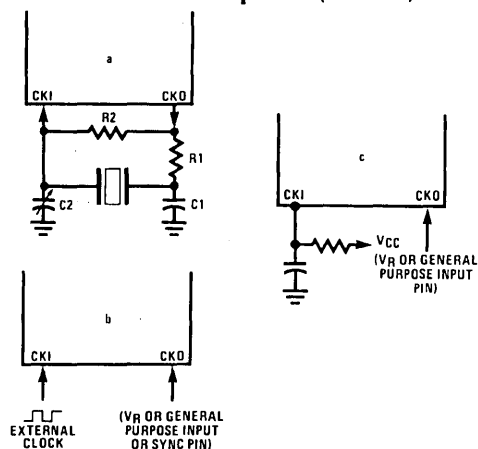

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

OSCILLATOR

There are four basic clock oscillator configurations available as shown by Figure 4.

- Crystal Controlled Oscillator.** CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 32 (optional by 16 or 8).
- External Oscillator.** CKI is an external clock input signal. The external frequency is divided by 32 (optional by 16 or 8) to give the instruction cycle time. CKO is now available to be used as the RAM power supply (V_R), as a general purpose input.
- RC Controlled Oscillator.** CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO is available as the RAM power supply (V_R) or as a general purpose input.

Functional Description (Continued)

TL/DD/6928-7

Crystal Oscillator

Crystal Value	Component Values			
	R1 (Ω)	R2 (Ω)	C1 (pF)	C2 (pF)

2.097 MHz	1k	1M	30	6-36

RC Controlled Oscillator

R (k Ω)	C (pF)	Instruction Cycle Time (μ s)
51	100	19 \pm 15%
82	56	19 \pm 13%

NOTE: 200 k Ω \geq R \geq 25 k Ω 360 pF \geq C \geq 50 pF

FIGURE 4. COP444L/445L Oscillator

CKO PIN OPTIONS

In a crystal controlled oscillator system, CKO is used as an output to the crystal network. As an option CKO can be a general purpose input, read into bit 2 of A (accumulator) upon execution of an INIL instruction. As another option, CKO can be a RAM power supply pin (V_R), allowing its connection to a standby/backup power supply to maintain the integrity of RAM data with minimum power drain when the main supply is inoperative or shut down to conserve power. Using either option is appropriate in applications where the COP444L/445L system timing configuration does not require use of the CKO pin.

I/O OPTIONS

COP444L/445L outputs have the following optional configurations, illustrated in Figure 5.

- Standard**—an enhancement mode device to ground in conjunction with a depletion-mode device to V_{CC} , compatible with LSTTL and CMOS input requirements. Available on SO, SK, and all D and G outputs.
- Open-Drain**—an enhancement-mode device to ground only, allowing external pull-up as required by the user's application. Available on SO, SK, and all D and G outputs.

c. Push-Pull—An enhancement-mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads. Available on SO and SK outputs only.

d. Standard L—same as a., but may be disabled. Available on L outputs only.

e. Open Drain L—same as b., but may be disabled. Available on L outputs only.

f. LED Direct Drive—an enhancement-mode device to ground and to V_{CC} , meeting the typical current sourcing requirements of the segments of an LED display. The sourcing device is clamped to limit current flow. These devices may be turned off under program control (See Functional Description, EN Register), placing the outputs in a high impedance state to provide required LED segment blanking for a multiplexed display. Available on L outputs only.

Note: Series current limiting resistors have to be used if the higher operating voltage option is selected and LEDs are driven directly.

g. TRI-STATE Push-Pull—an enhancement-mode device to ground and V_{CC} . These outputs are TRI-STATE outputs, allowing for connection of these outputs to a data bus shared by other bus drivers. Available on L outputs only.

COP444L/COP445L inputs have the following optional configurations:

h. An on-chip depletion load device to V_{CC} .

i. A Hi-Z input which must be driven to a "1" or "0" by external components.

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of six devices (numbered 1-6, respectively). Minimum and maximum current (I_{OUT} and V_{OUT} curves are given in Figure 6 for each of these devices to allow the designer to effectively use these I/O configurations in designing a system.

The SO, SK outputs can be configured as shown in a., b., or c. The D and G outputs can be configured as shown in a. or b. Note that when inputting data to the G ports, the G outputs should be set to "1". The L outputs can be configured in d., e., f. or g.

An important point to remember if using configuration d. or f. with the L drivers is that even when the L drivers are disabled, the depletion load device will source a small amount of current (see Figure 6, device 2); however, when the L-lines are used as inputs, the disabled depletion device can *not* be relied on to source sufficient current to pull an input to logic "1".

RAM KEEP-ALIVE OPTION

Selecting CKO as the RAM power supply (V_R) allows the user to shut off the chip power supply (V_{CC}) and maintain data in the lower four (Br = 0, 1, 2, 3) registers of RAM. To insure that RAM data integrity is maintained, the following conditions *must* be met:

- $\overline{\text{RESET}}$ must go low before V_{CC} goes low during power off; V_{CC} must go high before $\overline{\text{RESET}}$ goes high on power-up.
- V_R must be within the operating range of the chip, and equal to $V_{CC} \pm 1V$ during normal operation.
- V_R must be $\geq 3.3V$ with V_{CC} off.

Functional Description (Continued)

COP445L

If the COP444L is bonded as a 24-pin device, it becomes the COP455L, illustrated in *Figure 2*, COP444L/445L Connection Diagrams. Note that the COP445L does not contain

the four general purpose IN inputs (IN₃-IN₀). Use of this option precludes, of course, use of the IN options and the interrupt feature, which uses IN₁. All other options are available for the COP445L.

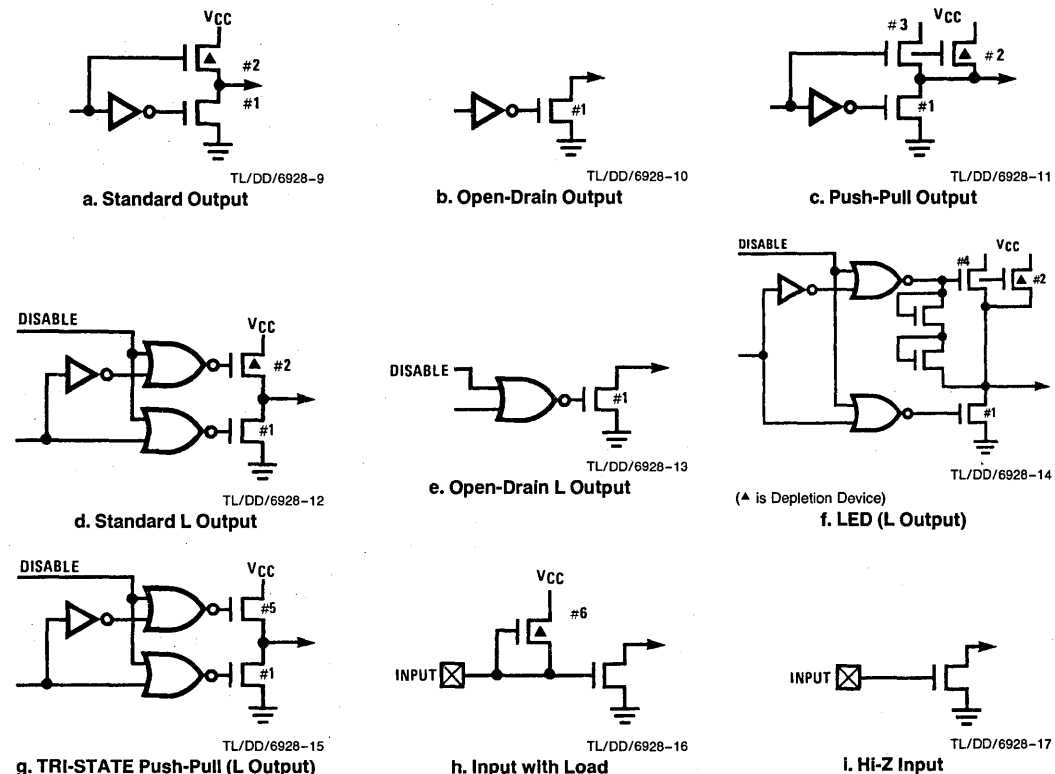

FIGURE 5. Output Configuration

L-Bus Considerations

False states may be generated on L₀-L₇ during the execution of the CAMQ instruction. The L-Ports should not be used as clocks for edge sensitive devices such as flip-flops, counters, shift registers, etc. The following short program illustrates this situation.

START:

```

CLRA          ;ENABLE THE Q
LEI 4         ;REGISTER TO L LINES
LBI TEST
STII 3
AISC 12

```

LOOP:

```

LBI TEST     ;LOAD Q WITH X'C3
CAMQ
JP LOOP

```

In this program the internal Q register is enabled onto the L lines and a steady bit pattern of logic highs is output on L₀, L₁, L₆, L₇, and logic lows on L₂-L₅ via the two-byte CAMQ instruction. Timing constraints on the device are such that the Q register may be temporarily loaded with the second byte of the CAMQ opcode (X'C3) prior to receiving the valid data pattern. If this occurs, the opcode will ripple onto the L lines and cause negative-going glitches on L₀, L₁, L₆, L₇, and positive glitches on L₂-L₅. Glitch durations are under 2 μ s, although the exact value may vary due to data patterns, processing parameters, and the L line loading. These false states are peculiar only to the CAMQ instruction and the L lines.

Typical Performance Characteristics

		3E	0011 1110			
OGI	y	33	0011 0011	y → G	None	Output to G Ports Immediate
		5-	0101 t			
OMG		33	0011 0011	RAM(B) → G	None	Output RAM to G Ports
		3A	0011 1010			
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 3)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: The ININ instruction is not available on the 24-pin COP445L or COP345L since these devices do not contain the IN inputs.

Note 3: For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.

Note 4: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 5: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 6: LBI is a single-byte instruction if d = 0, 9, 10, 11, 12, 13, 14 or 15. The machine code for the lower 4 bits equals the binary value of the "d" data minus 1, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 7: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP444L/445L programs.

SOFTWARE AND OPCODE DIFFERENCES IN THE COP444L INSTRUCTION SET

The COP444L is essentially a COP420L with a double RAM and ROM. Because of this increased memory space certain instructions have expanded capability in the COP444L. Note that there are no new instructions in the COP444L and that all instructions perform the same operations in the COP444L as they did in the COP420L. The expanded capability is merely to allow appropriate handling of the increased memory space. The affected instructions are:

JMP	a	(a = address)
JSR	a	(a = address)
LDD	r,d	(r,d = RAM address Br,Bd)
XAD	r,d	(r,d = RAM address Br,Bd)
LBI	r,d	(r,d = RAM address Br,Bd; only two byte form of the instruction affected)

XABR

The JMP and JSR instructions are modified in that the address a may be anywhere within the 2048 words of ROM space. The opcodes are as follows:

JMP	0110 0 a _{10:9:8}	JSR	0110 1 a _{10:9:8}
	a _{7:0}		a _{7:0}

The LDD, XAD, and two byte LBI are modified so that they may address the entire RAM space. The opcodes are as follows:

LDD	0110 0011	XAD	0010 0011
	0 r d		1 r d
LBI	0011 0011		
	1 r d		

The XABR instruction change is transparent to the user. The opcode is not changed nor is the function of the instruction. The change is that values of 0 through 7 in A will address registers in the COP444L (i.e., the lower three bits of A become the Br value following the instruction). In the COP420L, the lower two bits of A became the Br value following an XABR instruction.

Note that those instructions which have an exclusive-or argument (LD, X, XIS, XDS) are not affected. The argument is still two bits of the opcode. This means that the exclusive-or aspect of these instructions works within blocks of four registers. It is not possible to toggle Br from a value between 0 and 3 to a value between 4 and 7 by means of these instructions.

Description of Selected Instructions (Continued)

There are no other software or opcode differences between the COP444L and the COP420L. Examination of the above changes indicates that the existing opcodes for those instructions have merely been extended. There is no fundamental change.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the contents of ROM addressed by the 11-bit word, PC_{10:8}, A, M. PC₁₀, PC₉ and PC₈ are not affected by this instruction.

Note that JID requires 2 instruction cycles to execute.

INIL INSTRUCTION

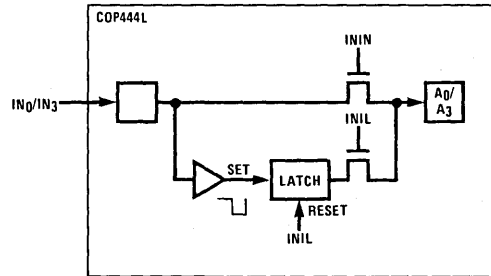

INIL (Input IL Latches to A) inputs 2 latches, IL₃ and IL₀ (see Figure 7) and CKO into A. The IL₃ and IL₀ latches are set if a low-going pulse ("1" to "0") has occurred on the IN₃ and IN₀ inputs since the last INIL instruction, provided the input pulse stays low for at least two instruction times. Execution of an INIL inputs IL₃ and IL₀ into A3 and A0 respectively, and resets these latches to allow them to respond to subsequent low-going pulses on the IN₃ and IN₀ lines. If CKO is mask programmed as a general purpose input, an INIL will input the state of CKO into A2. If CKO has not been so programmed, a "1" will be placed in A2. A "0" is always placed in A1 upon the execution of an INIL. The general purpose inputs IN₃-IN₀ are input to A upon execution of an ININ instruction. (See Table II, ININ instruction.) INIL is useful in recognizing pulses of short duration or pulses which occur too often to be read conveniently by an ININ instruction.

Note: IL latches are not cleared on reset; IL₃-IL₀ not input on 445L.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 11-bit word PC₁₀, PC₉, PC₈, A, M. LQID can be used for table lookup or code con-

version such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB → SC) and replaces the least significant 8 bits of PC as follows: A → PC_{7:4}, RAM(B) → PC_{3:0}, leaving PC₁₀, PC₉ and PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SC → SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SB → SC, the previous contents of SC are lost. Also, when LQID pops the stack, the previously pushed contents of SB are left in SC. The net result is that the contents of SB are placed in SC (SB → SC). Note that LQID takes two instruction cycle times to execute.

TL/DD/6928-21

FIGURE 7. INIL Hardware Implementation

SKT INSTRUCTION

The SKT (Skip On Timer) instruction tests the state of an internal 10-bit time-base counter. This counter divides the instruction cycle clock frequency by 1024 and provides a latched indication of counter overflow. The SKT instruction tests this latch, executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction, therefore, allow the COP444L/445L to generate its own time-base for real-time processing rather than relying on an external input signal.

For example, using a 2.097 MHz crystal as the time-base to the clock generator, the instruction cycle clock frequency will be 65 kHz (crystal frequency ÷ 32) and the binary counter output pulse frequency will be 64 Hz. For time-of-day or similar real-time processing, the SKT instruction can call a routine which increments a "seconds" counter every 64 ticks.

Description of Selected Instructions (Continued)

INSTRUCTION SET NOTES

- The first word of a COP444L/445L program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths except JID and LQID take the same number of cycle times whether instructions are skipped or executed. JID and LQID instructions take 2 cycles if executed and 1 cycle if skipped.
- The ROM is organized into 32 pages of 64 words each. The Program Counter is an 11-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3, 7, 11, 15, 19, 23 or 27 will access data in the next group of four pages.

Option List

The COP444L/445L mask-programmable options are assigned numbers which correspond with the COP444L pins.

The following is a list of COP444L options. When specifying a COP445L chip, Options 9, 10, 19, and 20 must all be set to zero. The options are programmed at the same time as the ROM pattern to provide the user with the hardware flexibility to interface to various I/O components using little or no external circuitry.

Option 1 = 0: Ground Pin—no options available

Option 2: CKO Output

- = 0: clock generator output to crystal/resonator
(0 not allowable value if option 3 = 3)
- = 1: pin is RAM power supply (V_R) input
- = 2: general purpose input, load device to V_{CC}
- = 3: general purpose input, Hi-Z

Option 3: CKI Input

- = 0: oscillator input divided by 32 (2 MHz max.)
- = 1: oscillator input divided by 16 (1 MHz max.)
- = 2: oscillator input divided by 8 (500 kHz max.)
- = 3: single-pin RC controlled oscillator divided by 4
- = 4: External Schmitt Trigger level clock divide by 4

Option 4: $\overline{\text{RESET}}$ Input

- = 0: load device to V_{CC}
- = 1: Hi-Z input

Option 5: L_7 Driver

- = 0: Standard output
- = 1: Open-drain output
- = 2: High current LED direct segment drive output
- = 3: High current TRI-STATE push-pull output
- = 4: Low-current LED direct segment drive output
- = 5: Low-current TRI-STATE push-pull output

Option 6: L_6 Driver

same as Option 5

Option 7: L_5 Driver

same as Option 5

Option 8: L_4 Driver

same as Option 5

Option 9: IN_1 Input

- = 0: load device to V_{CC}
- = 1: Hi-Z input

Option 10: IN_2 Input

same as Option 9

Option 11: V_{CC} pin Operating Voltage

- | COP44XL | COP34XL |
|---------------------|----------------|
| = 0: +4.5V to +6.3V | +4.5V to +5.5V |

Option 12: L_3 Driver

same as Option 5

Option 13: L_2 Driver

same as Option 5

Option 14: L_1 Driver

same as Option 5

Option 15: L_0 Driver

same as Option 5

Option 16: SI Input

same as Option 9

Option List (Continued)

Option 17: SO Driver

- = 0: standard output
- = 1: open-drain output
- = 2: push-pull output

Option 18: SK Driver

same as Option 17

Option 19: IN₀ Input

same as Option 9

Option 20: IN₃ Input

same as Option 9

Option 21: G₀ I/O Port

- = 0: very-high current standard output
- = 1: very-high current open-drain output
- = 2: high current standard output
- = 3: high current open-drain output
- = 4: standard LSTTL output (fanout = 1)
- = 5: open-drain LSTTL output (fanout = 1)

Option 22: G₁ I/O Port

same as Option 21

Option 23: G₂ I/O Port

same as Option 21

Option 24: G₃ I/O Port

same as Option 21

Option 25: D₃ Output

same as Option 21

Option 26: D₂ Output

same as Option 21

Option 27: D₁ Output

same as Option 21

Option 28: D₀ Output

same as Option 21

Option 29: L Input Levels

- = 0: standard TTL input levels
("0" = 0.8V, "1" = 2.0V)
- = 1: higher voltage input levels
("0" = 1.2V, "1" = 3.6V)

Option 30: IN Input Levels

same as Option 29

Option 31: G Input Levels

same as Option 29

Option 32: SI Input Levels

same as Option 29

Option 33: RESET Input

- = 0: Schmitt trigger input levels
- = 1: standard TTL input levels
- = 2: higher voltage input levels

Option 34: CKO Input Levels (CKO=input; Option 2=2, 3)
same as Option 29

Option 35: COP Bonding

- = 0: COP444L (28-pin device)
- = 1: COP445L (24-pin device)
- = 2: both 28- and 24-pin versions

Option 36: Internal Initialization Logic

- = 0: normal operation
- = 1: no internal initialization logic

COP444L Option Table

The following option information is to be sent to National along with the EPROM.

OPTION DATA	OPTION DATA
OPTION 1 VALUE= <u> 0 </u> IS: GROUND PIN	OPTION 21 VALUE= <u> </u> IS: G0 I/O PORT

OPTION 20 VALUE= <u> </u> IS: IN3 INPUT	

Typical Applications

TEST MODE (NON-STANDARD OPERATION)

The SO output has been configured to provide for standard test procedures for the custom-programmed COP444L. With SO forced to logic "1", two test modes are provided, depending upon the value of SI:

- a. RAM and Internal Logic Test Mode (SI = 1)
- b. ROM Test Mode (SI = 0)

These special test modes should not be employed by the user; they are intended for manufacturing test only.

APPLICATION # 1: COP444L GENERAL CONTROLLER

Figure 8 shows an interconnect diagram for a COP444L used as a general controller. Operation of the system is as follows:

1. The L₇-L₀ outputs are configured as LED Direct Drive outputs, allowing direct connection to the segments of the display
2. The D₃-D₀ outputs drive the digits of the multiplexed display directly and scan the columns of the 4 x 4 keyboard matrix.
3. The IN₃-IN₀ inputs are used to input the 4 rows of the keyboard matrix. Reading the IN lines in conjunction with the current value of the D outputs allows detection, debouncing, and decoding of any one of the 16 keyswitches.
4. CKI is configured as a single-pin oscillator input allowing system timing to be controlled by a single-pin RC network. CKO is therefore available for use as a general-purpose input.

5. SI is selected as the input to a binary counter input. With SIO used as a binary counter, SO and SK can be used as general purpose outputs.
6. The 4 bidirectional G I/O ports (G₃-G₀) are available for use as required by the user's application.
7. Normal reset operation is selected.

COP444L EVALUATION (See COP Note 4)

The 444L-EVAL is a pre-programmed COP444L, containing several routines which facilitate user familiarization and evaluation of the COP444L operating characteristics. It may be used as an up/down counter or timer, interfacing to any combination of (1) an LED digit or lamps, (2) 4-digit LED Display Controller, (3) a 4-digit VF Display Controller, and/or (4) a 4-digit LCD Display Controller. Alternatively, it may be used as a simple music synthesizer.

SAMPLE CIRCUITS

1. By making only the oscillator, power supply and "L7" connections, (Figure 9) an approximate 1 Hz square wave will be produced at output "D1." This output may be observed with an oscilloscope, or connected to additional TTL or CMOS circuitry.
2. By making the indicated connections to a small LED digit (NSA1541A, NSA1166, or equiv.—larger digits will be proportionately dimmer), the counter actions may be observed. Place the "up/down" switch in the "up" (open) position and apply a TTL-compatible signal at the "counter-input." Placing the "up/down" switch in the "down" (closed) position causes the count to decrement on each high-to-low input transition.
3. All 4 digits of the counter may be displayed by connecting a standard display controller (COP472 for LCD, MM5450 for LED) as shown in Figure 9.

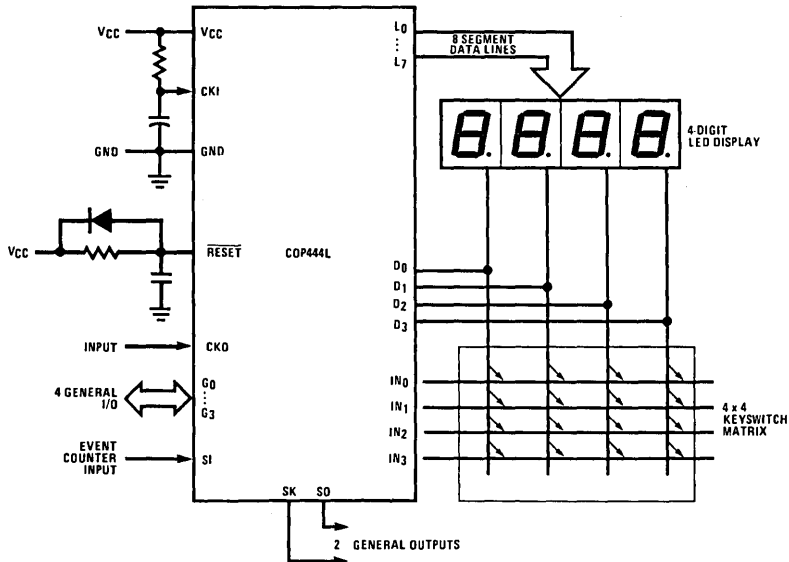

FIGURE 8. COP444L Keyboard/Display Interface

TL/DD/6928-22

Typical Applications (Continued)

Any combination of the single LED digit and display controllers may be used simultaneously, and will display the same data.

4. The simple counter described above becomes a timer when the 1 Hz output is connected to the "counter input." Up or down counting may be used with input frequencies up to 1 kHz. Improved timing accuracies may be obtained by substituting the 2.097 MHz crystal oscillator circuit of *Figure 4a* for the RC network shown in *Figure 9*, or by connecting a more stable external frequency to the "counter input" in place of the 1 Hz signal.
5. An "entertaining" use of the 444L-EVAL is as a simple music synthesizer (or electronic organ). By attaching a simple switch matrix (or keyboard), a speaker or piezo-ceramic transducer, and grounding "L7", the user can play "music" (*Figure 10*). Three modes of operation are available: Play a note, play one of four stored tunes, or record a tune for subsequent replay.

a. Play A Note

Twelve keys, representing the 12 notes in one octave, are labeled "C" through "B"; depressing a key causes

a square wave of the corresponding frequency to be outputted to the speaker. Depressing "LShift" or "UShift" causes the next note to be shifted to the next lower octave (one-half frequency) or the next upper octave (double frequency), respectively.

b. Play Stored Tune

Depressing "Play" followed by " $\frac{1}{8}$ ", " $\frac{1}{4}$ ", " $\frac{1}{2}$ ", or "1" will cause one of 4 stored tunes to be played.

c. Record Tune

Any combination of notes and rests up to a total of 48 may be stored in RAM for later replay. To store a note, press the appropriate note key, followed by the duration of the note ($\frac{1}{8}$ -note, $\frac{1}{4}$ -note, $\frac{1}{2}$ -note, whole (1)-note, followed by "Store"; a rest is stored by selecting the duration and pressing "Store." When the tune is complete, press "Play" followed by "Store"; the tune will be played for immediate audition. Subsequent depression of "Play" and "Store" will replay the last stored tune.

Note: The accuracy of the tones produced is a function of the oscillator accuracy and stability; the crystal oscillator is recommended.

COP401L ROMless N-Channel Microcontroller

General Description

The COP401L ROMless Microcontroller is a member of the COPSM family of microcontrollers, fabricated using N-channel, silicon gate MOS technology. The COP401L contains CPU, RAM, I/O and is identical to a COP410L device except the ROM has been removed and pins have been added to output the ROM address and to input the ROM data. In a system the COP401L will perform exactly as the COP410L. This important benefit facilitates development and debug of a COP program prior to masking the final part.

The COP401L is intended for emulation only, not intended for volume production. Use COP402 or COP404L for volume production.

Features

- Circuit equivalent of COP410L
- Low cost
- Powerful instruction set
- 512 x 8 ROM, 32 x 4 RAM
- Separate RAM power supply pin for RAM keep-alive applications
- Two-level subroutine stack
- 15 μ s instruction time
- Single supply operation (4.5–5.5V)
- Low current drain (8 mA max.)
- Internal binary counter register with serial I/O
- MICROWIRETM compatible serial I/O
- General purpose outputs
- LSTTL/CMOS compatible in and out
- Direct drive of LED digit and segment lines
- Software/hardware compatible with other members of COP400 family
- Pin-for-pin compatible with COP402 and COP404L

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at any Pin Relative to GND	-0.5V to +10V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	-65°C to +150°C
Lead Temp. (Soldering, 10 sec.)	300°C

Power Dissipation	0.75W at 25°C
	0.4W at 70°C
Total Source Current	120 mA
Total Sink Current	120 mA

Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$, $4.5\text{V} \leq V_{CC} \leq 5.5\text{V}$ unless otherwise noted

Parameter	Conditions	Min	Max	Units
Operating Voltage (V_{CC})		4.5	5.5	V
Power Supply Ripple (Notes 2, 3)	Peak to Peak		0.5	V

Functional Description

A block diagram of the COP401L is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2 volts). When a bit is reset, it is a logic "0" (less than 0.8 volts).

PROGRAM MEMORY

Program Memory consists of a 512-byte external memory. As can be seen by an examination of the COP401L instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words each.

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by the 9-bit subroutine save registers, SA and SB, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 128-bit RAM, organized as 4 data registers of 8 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper 2 bits (Br) select 1 of 4 data registers and lower 3 bits of the 4-bit Bd select 1 of 8 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3, 15 instruction. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs. The most significant bit of Bd is not used to select a RAM digit. Hence each physical digit of RAM may be selected by two different values of Bd as shown in *Figure 4* below. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 and 15, but NOT between 7 and 8 (see Table 3).

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

TL/DD/6913-4

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Bd portion of the B register, to load 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions of the COP401L, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below.)

The G register contents are outputs to 4 general-purpose bidirectional I/O ports.

The Q register is an internal, latched, 8-bit register, used to hold data loaded from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M. L I/O ports can be directly connected to the segments of a multiplexed LED display (using the LED Direct Drive output configuration option) with Q data being outputted to the Sa-Sg and decimal point segments of the display.

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift register.

The XAS instruction copies C into the SKL Latch. In the counter mode, SK is the output of SKL in the shift register mode, SK outputs SKL ANDed with internal instruction cycle clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN₃-EN₀).

1. The least significant bit of the enable register, EN₀, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.

2. EN₁ is not used. It has no effect on COP401L operation.

Functional Description (Continued)

TABLE I. Enable Register Modes—Bits EN_3 and EN_0

EN_3	EN_0	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = Clock If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = Clock If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

- With EN_2 set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN_2 disables the L drivers, placing the L I/O ports in a high-impedance input state.
- EN_3 , in conjunction with EN_0 , affects the SO output. With EN_0 set (binary counter option selected) SO will output the value loaded into EN_3 . With EN_0 reset (serial shift register option selected), setting EN_3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN_3 with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0". Table I provides a summary of the modes associated with EN_3 and EN_0 .

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below (Figure 5). The RESET pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC} . Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

TL/DD/6913-5

$RC \geq$ Power Supply Rise Time

FIGURE 5. Power-Up Clear Circuit

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

EXTERNAL MEMORY INTERFACE

The COP401L is designed for use with an external Program Memory. This memory may be implemented using any devices having the following characteristics:

- random addressing
- TTL-compatible TRI-STATE® outputs
- TTL-compatible inputs
- access time = 5 μ s max.

Typically these requirements are met using bipolar or MOS PROMs.

During operation, the address of the next instruction is sent out on P8 and IP7 through IP0 during the time that AD/DATA is high (logic "1" = address mode). Address data on the IP lines is stored into an external latch on the high-to-low transition of the AD/DATA line; P8 is a dedicated address output, and does not need to be latched. When AD/DATA is low (logic "0" = data mode), the output of the memory is gated onto IP7 through IP0, forming the input bus. Note that the AD/DATA output has a period of one instruction time, a duty cycle of approximately 50%, and specifies whether the IP lines are used for address output or instruction input.

OSCILLATOR

CKI is an external clock input signal. The external frequency is divided by 32 to give the instruction cycle time. The divide-by-32 configuration was chosen to make the COP 401L compatible with the COP404L and the COPS™ Development System. However, the $\div 32$ configuration is not available on the COP410L/COP411L. It is therefore possible to exactly emulate the system speed (cycle time), but not possible to drive the 401L with the system clock during emulation.

Functional Description (Continued)

CKO (RAM POWER)

CKO is configured as a RAM power supply pin (V_R), allowing its connection to a standby/backup power supply to maintain the integrity of RAM data with minimum power drain when the main supply is inoperative or shut down to conserve power. This pin must be connected to V_{CC} if the power backup feature is not used. To insure that RAM integrity is maintained, the following conditions must be met:

1. \overline{RESET} must go low before V_{CC} goes below spec during power-off; V_{CC} must be within spec before \overline{RESET} goes high on power-up.
2. During normal operation, V_R must be within the operating range of the chip with $(V_{CC}-1) \leq V_R \leq V_{CC}$.
3. V_R must be $\geq 3.3V$ with V_{CC} off.

INPUT/OUTPUT CONFIGURATIONS

COP401L outputs have the following configurations, illustrated in *Figure 6*:

- Standard**—an enhancement mode device to ground in conjunction with a depletion-mode device to V_{CC} , compatible with LSTTL and CMOS input requirements. (Used on D and G outputs.)
- Open-Drain**—an enhancement-mode device to ground only, allowing external pull-up as required by the user's application. (Used on IP, P and SKIP outputs.)
- Push-Pull**—An enhancement-mode device to ground in conjunction with a depletion-mode device paralleled en-

hancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads. (Used on SO and SK outputs.)

- LED Direct Drive**—an enhancement-mode device to ground and to V_{CC} , meeting the typical current sourcing requirements of the segments of an LED display. The sourcing device is clamped to limit current flow. These devices may be turned off under program control (See Functional Description, EN Register), placing the outputs in a high-impedance state to provide required LED segment blanking for a multiplexed display. (Used on L outputs.)

COP401L inputs have an on-chip depletion load device to V_{CC} .

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of five devices (numbered 1–5, respectively). Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 7* for each of these devices to allow the designer to effectively use these I/O configurations in designing a system.

An important point to remember is that even when the L drivers are disabled, the depletion load device will source a small amount of current (see *Figure 7*, Device 2); however, when the L-lines are used as inputs, the disabled depletion device can *not* be relied on to source sufficient current to pull an input to a logic "1".

COP401L Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions, and description associated with each instruction in the COP401L instruction set.

TABLE II. COP401L Instruction Set Table Symbols

Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS	
A	4-bit Accumulator
B	6-bit RAM Address Register
Br	Upper 2 bits of B (register address)
Bd	Lower 4 bits of B (digit address)
C	1-bit Carry Register
D	4-bit Data Output Port
EN	4-bit Enable Register
G	4-bit Register to latch data for G I/O Port
L	8-bit TRI-STATE I/O Port
M	4-bit contents of RAM Memory pointed to by B Register
PC	9-bit ROM Address Register (program counter)
Q	8-bit Register to latch data for L I/O Port
SA	9-bit Subroutine Save Register A
SB	9-bit Subroutine Save Register B
SIO	4-bit Shift Register and Counter
SK	Logic-Controlled Clock Output

Symbol	Definition
INSTRUCTION OPERAND SYMBOLS	
d	4-bit Operand Field, 0-15 binary (RAM Digit Select)
r	2-bit Operand Field, 0-3 binary (RAM Register Select)
a	9-bit Operand Field, 0-511 binary (ROM Address)
y	4-bit Operand Field, 0-15 binary (Immediate Data)
RAM(s)	Contents of RAM location addressed by s
ROM(t)	Contents of ROM location addressed by t
OPERATIONAL SYMBOLS	
+	Plus
-	Minus
→	Replaces
↔	Is exchanged with
=	Is equal to
\bar{A}	The one's complement of A
⊕	Exclusive-OR
:	Range of values

INPUT/OUTPUT INSTRUCTIONS						
ING		33 2A	0011 0011 0010 1010	G → A	None	Input G Ports to A
INL		33 2E	0011 0011 0010 1110	L _{7:4} → RAM(B) L _{3:0} → A	None	Input L Ports to RAM, A
OBD		33 3E	0011 0011 0011 1110	Bd → D	None	Output Bd to D Outputs
OMG		33 3A	0011 0011 0011 1010	RAM(B) → G	None	Output RAM to G Ports
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 2)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: For additional information on the operation of the XAS, JID, and LQID instructions, see below.

Note 3: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 4: A JSRP transfers program control to subroutine page 2 (010 is loaded into the upper 3 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 5: The machine code for the lower 4 bits of the LBI instruction equals the binary value of the "d" data minus 1, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 6: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP401L programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the *contents* of ROM addressed by the 9-bit word, PC₈, A, M. PC₈ is not affected by this instruction.

Note that JID requires 2 instruction cycles to execute.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 9-bit word PC₈, A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB) and replaces the least significant 8 bits of PC as follows: A → PC_{7,4}, RAM(B) → PC_{3,0}, leaving PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SA → SB, the previous contents of SB are lost. Also, when LQID pops the stack, the previously pushed contents of SA are left in SB. The net result is that the contents of SA are placed in SB (SA → SB). Note that LQID takes two instruction cycle times to execute.

INSTRUCTION SET NOTES

- The first word of a COP401L program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths except JID and LQID take the same number of cycle times whether instructions are skipped or executed. JID and LQID instructions take 2 cycles if executed and 1 cycle if skipped.
- The ROM is organized into 8 pages of 64 words each. The Program Counter is a 9-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3 or 7 will access data in the next group of 4 pages.

Typical Applications

PROM-BASED SYSTEM

The COP401L may be used to emulate the COP410L. *Figure 8* shows the interconnect to implement a COP401L hardware emulation. This connection uses one MM5204 EPROM as external memory. Other memory can be used such as bipolar PROM or RAM.

Pins IP₇–IP₀ are bidirectional inputs and outputs. When the AD/ $\overline{\text{DATA}}$ clocking output turns on, the EPROM drivers are disabled and IP₇–IP₀ output addresses. The 8-bit latch (MM74C373) latches the address to drive the memory.

When AD/ $\overline{\text{DATA}}$ turns off, the EPROM is enabled and the IP₇–IP₀ pins will input the memory data. PB outputs the most significant address bit to the memory. (SKIP output may be used for program debug if needed.)

24 of the COP401L pins may be configured exactly the same as a COP410L.

Typical Applications (Continued)

Option Table

COP401L MASK OPTIONS

The following COP401L options have been implemented in this basic version of the COP401L.

Option Value	Comment	Option Value	Comment
Option 1 = 0	Ground—no option	Option 14 = 0	SI has load to V_{CC}
Option 2 = 1	CKO is RAM power supply input	Option 15 = 2	SO is push-pull output
Option 3 = N/A	CKI is external clock divide-by-32 (not available on COP401L)	Option 16 = 2	SK is push-pull output
Option 4 = 0	Reset has load to V_{CC}	Option 17 = 0	
Option 5 = 2		Option 18 = 0	G outputs are standard
Option 6 = 2		Option 19 = 0	
Option 7 = 2	L outputs are LED direct-drive	Option 20 = 0	
Option 8 = 2		Option 21 = 0	
Option 9 = 1	V_{CC} pin 4.5V to 9.5V operation	Option 22 = 0	D outputs are standard very high current
Option 10 = 2		Option 23 = 0	
Option 11 = 2		Option 24 = 0	
Option 12 = 2	L outputs are LED direct-drive	Option 25 = 0	L
Option 13 = 2		Option 26 = 0	G Have standard TTL input levels
		Option 27 = 0	SI
		Option 28 = N/A	40-pin package

COP401L-X13/COP401L-R13 ROMless N-Channel Microcontroller

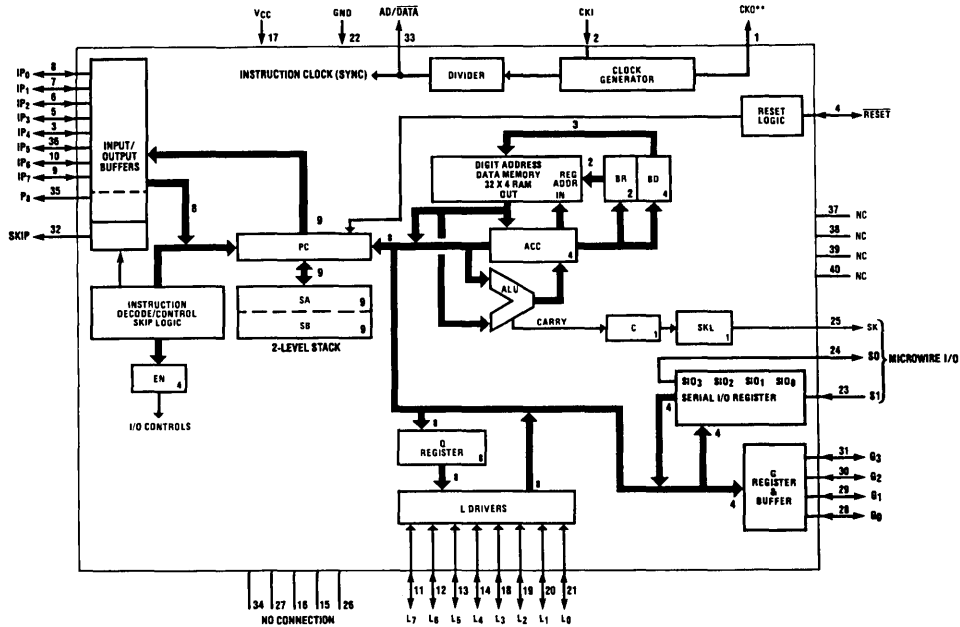

General Description

The COP401L-X13/COP401L-R13 ROMless Microcontrollers are members of the COPSTM family of microcontrollers, fabricated using N-channel, silicon gate MOS technology. The COP401L-X13/COP401L-R13 contain CPU, RAM, I/O and are identical to a COP413L device except the ROM has been removed and pins have been added to output the ROM address and to input the ROM data. In a system the COP401L-X13/COP401L-R13 will perform exactly as the COP413L. This important benefit facilitates development and debug of a COP program prior to masking the final part. There are two clock oscillator configurations available. The crystal oscillator configuration is called COP401L-X13 and the RC oscillator configuration is called COP401L-R13.

Features

- Circuit equivalent of COP413L
- Low cost
- Powerful instruction set
- 512 × 8 ROM, 32 × 4 RAM
- Two-level subroutine stack
- 16 μs instruction time
- Single supply operation (4.5–5.5V)
- Low current drain (8 mA max)
- Internal binary counter register with serial I/O
- MICROWIRE™ compatible serial I/O
- General purpose outputs
- Software/hardware compatible with other members of COP400 family
- Pin-for-pin compatible with COP402 and COP404L
- High noise immunity inputs ($V_{IL} = 1.2V$, $V_{IH} = 3.6V$)

TL/DD/8528-3

Functional Description

A block diagram of the COP401L-X13/COP401L-R13 is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2 volts). When a bit is reset, it is a logic "0" (less than 0.8 volts).

PROGRAM MEMORY

Program Memory consists of a 512-byte external memory. As can be seen by an examination of the COP401L-X13/COP401L-R13 instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 8 pages of 64 words each.

ROM addressing is accomplished by a 9-bit PC register. Its binary value selects one of the 512 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 9-bit binary count value. Two levels of subroutine nesting are implemented by the 9-bit subroutine save registers, SA and SB, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 128-bit RAM, organized as 4 data registers of 8 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper 2 bits (Br) select 1 of 4 data registers and lower 3 bits of the 4-bit Bd select 1 of 8 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the XAD 3,15 instruction.

The most significant bit of Bd is not used to select a RAM digit. Hence each physical digit of RAM may be selected by two different values of Bd as shown in *Figure 4* below. The skip condition for XIS and XDS instructions will be true if Bd changes between 0 and 15, but NOT between 7 and 8 (see Table 3).

FIGURE 4. RAM Digit Address to Physical RAM Digit Mapping

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Bd portion of the B register, to load 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions of the COP401L-X13/COP401L-R13, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below).

The G register contents are outputs to 4 general-purpose bidirectional I/O ports.

The Q register is an internal, latched, 8-bit register, used to hold data loaded from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M.

The SIO register functions as a 4-bit serial-in-/serial-out shift register or as a binary counter depending on the contents of the EN Register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in-/parallel-out shift registers.

The XAS instruction copies C into the SKL Latch. In the counter mode, SK is the output of SKL in the shift register mode, SK outputs SKL ANDed with internal instruction cycle clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN registers (EN₃-EN₀).

1. The least significant bit of the enable register, EN₀, selects the SIO Register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, decrementing its value by one upon each low-going pulse ("1" to "0") occurring on the SI Input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO Output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.
2. EN₁ is not used. It has no effect on COP401L-X13/COP401L-R13 operation.
3. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN₂ disables the L drivers, placing the L I/O ports in a high impedance input state.

TL/DD/8528-4

Functional Description (Continued)

TABLE I. Enable Register Modes - Bits EN₃ and EN₀

EN ₃	EN ₀	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = Clock If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = Clock If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

4. EN₃, in conjunction with EN₀, affects the SO output. With EN₀ set (binary counter option selected) SO will output the value loaded into EN₃. With EN₀ reset (serial shift register option selected), setting EN₃ enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN₃ with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0". Table 1 provides a summary of the modes associated with EN₃ and EN₀.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below (Figure 5). The RESET pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC}. Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

Figure 5. Power-Up Clear Circuit

TL/DD/8528-5

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

EXTERNAL MEMORY INTERFACE

The COP401L-X13/COP401L-R13 is designed for use with an external Program Memory. This memory may be implemented using any devices having the following characteristics:

1. random addressing
2. TTL-compatible TRI-STATE[®] outputs

3. TTL-compatible inputs

4. access time = 5 μ s max.

Typically these requirements are met using bipolar or MOS PROMs.

During operation, the address of the next instruction is sent out on P8 and IP7 through IP0 during the time that AD/DAT \bar{A} is high (logic "1" = address mode). Address data on the IP lines is stored into an external latch on the high-to-low transition of the AD/DAT \bar{A} line; P8 is a dedicated address output, and does not need to be latched. When AD/DAT \bar{A} is low (logic "0" = data mode), the output of the memory is gated onto IP7 through IP0, forming the input bus. Note that the AD/DAT \bar{A} output has a period of one instruction time, a duty cycle of approximately 50%, and specifies whether the IP lines are used for address output or instruction input.

OSCILLATOR

There are two basic clock oscillator configurations available as shown by Figure 6.

- a. The COP401L-X13 is a Resonator Controlled Oscillator. CKI and CKO are connected to an external ceramic resonator. The instruction cycle frequency equals the resonator frequency divided by 8.
- b. The COP401L-R13 is a RC Controlled Oscillator. CKI is configured as a single pin RC controlled Schmitt trigger oscillator. The instruction cycle equals the oscillation frequency divided by 4. CKO becomes no connection.

220 pF \geq C \geq 50 pF

I/O CONFIGURATIONS

COP401L-X13/COP401L-R13 inputs and outputs have the following configurations, illustrated in *Figure 7*.

- G0–G3—an enhancement mode device to ground in conjunction with depletion-mode device to V_{CC} .
- SO, SK, IP0–IP7, P8, SKIP, AD/DATA—an enhancement mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to V_{CC} . This configuration has been provided to allow for fast rise and fall times when driving capacitive loads.
- L0–L7—same as a, but may be disabled.
- SI has on-chip depletion load device to V_{CC} .
- $\overline{\text{RESET}}$ has a Hi-Z input which must be driven to a "1" or "0" by external components.

Curves are given in *Figure 8* to allow the designer to effectively use the I/O configurations in designing a system.

An important point to remember is that even when the L drivers are disabled, the depletion load device will source a small amount of current, however, when the L lines are used as inputs, the disabled depletion device can not be relied on to source sufficient current to pull an input to a logic "1".

Typical Performance Characteristics

COP401L-X13/COP401L-R13 Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions, and description associated with each instruction in the COP401L-X13/COP401L-R13 instruction set.

TABLE II. COP401L-X13/COP401L-R13 Instruction Set Table Symbols

Symbol	Definition
Internal Architecture Symbols	
A	4-bit Accumulator
B	6-bit RAM Address Register
Br	Upper 2 bits of B (register address)
Bd	Lower 4 bits of B (digit address)
C	1-bit Carry Register
EN	4-bit Enable Register
G	4-bit Register to latch data for G I/O Port
L	8-bit TRI-STATE I/O Port
M	4-bit contents of RAM Memory pointed to by B Register
PC	9-bit ROM Address Register (program counter)
Q	8-bit Register to latch data for L I/O Port
SA	9-bit Subroutine Save Register A
SB	9-bit Subroutine Save Register B
SIO	4-bit Shift Register and Counter
SK	Logic Controlled Clock Output
Instruction Operand Symbols	
d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
r	2-bit Operand Field, 0–3 binary (RAM Register Select)
a	9-bit Operand Field, 0–511 binary (ROM Address)
y	4-bit Operand Field, 0–15 binary (Immediate Data)
RAM(s)	Contents of RAM location addressed by s
ROM(t)	Contents of ROM location addressed by t
Operational Symbols	
+	Plus
–	Minus
→	Replaces
↔	Is exchanged with
=	Is equal to
\bar{A}	The one's complement of A
⊕	Exclusive-OR
:	Range of values

TABLE III. COP401L-X13/COP401L-R13 Instruction Set

Mnemonic	Operand	Hex Code	Machine Language Code (Binary)	Data Flow	Skip Conditions	Description
ARITHMETIC INSTRUCTIONS						
ASC		30	0011 0000	$A + C + \text{RAM}(B) \rightarrow A$ Carry $\rightarrow C$	Carry	Add with Carry, Skip on Carry
ADD		31	0011 0001	$A + \text{RAM}(B) \rightarrow A$	None	Add RAM to A
AISC	y	5-	0101 y	$A + y \rightarrow A$	Carry	Add Immediate, Skip on Carry ($y \neq 0$)
CLRA		00	0000 0000	$0 \rightarrow A$	None	Clear A
COMP		40	0100 0000	$\bar{A} \rightarrow A$	None	One's complement of A to A
NOP		44	0100 0100	None	None	No Operation
RC		32	0011 0010	"0" $\rightarrow C$	None	Reset C
SC		22	0010 0010	"1" $\rightarrow C$	None	Set C
XOR		02	0000 0010	$A \oplus \text{RAM}(B) \rightarrow A$	None	Exclusive-OR RAM with A
TRANSFER OF CONTROL INSTRUCTIONS						
JID		FF	1111 1111	$\text{ROM}(\text{PC}_8, \text{A}, \text{M}) \rightarrow \text{PC}_{7:0}$	None	Jump Indirect (Note 2)
JMP	a	6-	0110 000 a ₈	$a \rightarrow \text{PC}$	None	Jump
JP	a	-	1 a _{6:0}	$a \rightarrow \text{PC}_{6:0}$	None	Jump within-Page (Note 3)
			(pages 2, 3 only) or			
			11 a _{5:0}	$a \rightarrow \text{PC}_{5:0}$		
			(all other pages)			
JSRP	a	-	10 a _{5:0}	$\text{PC} + 1 \rightarrow \text{SA} \rightarrow \text{SB}$	None	Jump to Subroutine Page (Note 4)
				$010 \rightarrow \text{PC}_{8:6}$ $a \rightarrow \text{PC}_{5:0}$		
JSR	a	6-	0110 100 a ₈	$\text{PC} + 1 \rightarrow \text{SA} \rightarrow \text{SB}$	None	Jump to Subroutine
			a _{7:0}	$a \rightarrow \text{PC}$		
RET		48	0100 1000	$\text{SB} \rightarrow \text{SA} \rightarrow \text{PC}$	None	Return from Subroutine
RETSK		49	0100 1001	$\text{SB} \rightarrow \text{SA} \rightarrow \text{PC}$	Always Skip on Return	Return from Subroutine then Skip
MEMORY REFERENCE INSTRUCTIONS						
CAMQ		33	0011 0011	$A \rightarrow \text{Q}_{7:4}$	None	Copy A, RAM to Q
		3C	0011 1100	$\text{RAM}(B) \rightarrow \text{Q}_{3:0}$		
LD	r	-5	00 r 0101	$\text{RAM}(B) \rightarrow A$	None	Load RAM into A,
				$\text{Br} \oplus r \rightarrow \text{Br}$		Exclusive-OR Br with r
LQID		BF	1011 1111	$\text{ROM}(\text{PC}_8, \text{A}, \text{M}) \rightarrow \text{Q}$	None	Load Q Indirect (Note 2)
				$\text{SA} \rightarrow \text{SB}$		
RMB	0	4C	0100 1100	$0 \rightarrow \text{RAM}(B)_0$	None	Reset RAM Bit
	1	45	0100 0101	$0 \rightarrow \text{RAM}(B)_1$		
	2	42	0100 0010	$0 \rightarrow \text{RAM}(B)_2$		
	3	43	0100 0011	$0 \rightarrow \text{RAM}(B)_3$		
SMB	0	4D	0100 1101	$1 \rightarrow \text{RAM}(B)_0$	None	Set RAM Bit
	1	47	0100 0111	$1 \rightarrow \text{RAM}(B)_1$		
	2	46	0100 0110	$1 \rightarrow \text{RAM}(B)_2$		
	3	4B	0100 1011	$1 \rightarrow \text{RAM}(B)_3$		
STII	y	7-	0111 y	$y \rightarrow \text{RAM}(B)$	None	Store Memory Immediate and Increment Bd
				$\text{Bd} + 1 \rightarrow \text{Bd}$		Increment Bd
X	r	-6	00 r 0110	$\text{RAM}(B) \leftrightarrow A$	None	Exchange RAM with A,
				$\text{Br} \oplus r \rightarrow \text{Br}$		Exclusive-OR Br with r

		3A	<u>0011</u> <u>1010</u>			
XAS		4F	<u>0100</u> <u>1111</u>	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 2)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined) Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: For additional information on the operation of the XAS, JID, and LQID instructions, see below.

Note 3: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 4: A JSRP transfers program control to subroutine page 2 (010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 5: The machine code for the lower 4 bits of the LBI instruction equals the binary value of the "d" data *minus 1* e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 6: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP401L-X13/COP401L-R13 programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the *contents* of ROM addressed by the 9-bit word, PC₈, A, M. PC₈ is not affected by this instruction.

Note that JID requires 2 instruction cycles to execute.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 9-bit word PC₈, A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB) and replaces the least significant 8 bits of PC as follows: A → PC_{7:4}, RAM (B) → PC_{3:0}, leaving PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SA → SB, the previous contents of SB are lost. Also, when LQID pops the stack, the previously pushed contents of SA are left in SB. The net result is that the contents of SA are placed in SB (SA → SB). Note that LQID takes two instruction cycle times to execute.

INSTRUCTION SET NOTES

- The first word of a COP401L-X13/COP401L-R13 program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths except JID and LQID take the same number of cycle times whether instructions are skipped or executed. JID and LQID instructions take 2 cycles if executed and 1 cycle if skipped.

- The ROM is organized into 8 pages of 64 words each. The Program Counter is a 9-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3 or will access data in the next group of 4 pages.

COPS Programming Manual

For detailed information on writing COPS programs, the COPS Programming Manual 424410284-001 provides an in-depth discussion of the COPS architecture, instruction set and general techniques of COPS programming. This manual is written with the programmer in mind.

Typical Applications

PROM-Based System

The COP401L-X13/COP401L-R13 may be used to emulate the COP413L. *Figure 9* shows the interconnect to implement a COP401L-X13/COP401L-R13 hardware emulation. This connection uses one MM2716 EPROM as external memory. Other memory can be used such as bipolar PROM or RAM.

Pins IP₇-IP₀ are bidirectional inputs and outputs. When the AD/ \overline{DATA} clocking output turns on, the EPROM drivers are disabled and IP₇-IP₀ output addresses. The 8-bit latch (MM74C373) latches the addresses to drive the memory.

When AD/ \overline{DATA} turns off, the EPROM is enabled and the IP₇-IP₀ pins will input the memory data. P8 outputs the most significant address bit to the memory. (SKIP output may be used for program debug if needed.)

Twenty of the COP401L-X13/COP401L-R13 pins may be configured exactly the same as the COP413L. Selection of the COP401L-X13 or COP401L-R13 depends upon which oscillator is selected for the COP413L.

Oscillator Requirement

	Order ROMless
COP413L Option 1 = 0	Ceramic Resonator or external input frequency divided by 8. CKO is oscillator out.
Option 1 = 1	Single Pin RC controlled oscillator divided by 4. CKO is no connection.

COP402-5 ROMless N-Channel Microcontroller

General Description

The COP402-5 ROMless Microcontroller is a member of the COPSTM family, fabricated using N-channel silicon gate MOS technology. The part contains CPU, RAM, and I/O, and is identical to a COP420 device, except the ROM has been removed; pins have been added to output the ROM address and to input ROM data. In a system, the COP402 will perform exactly as the COP420; this important benefit facilitates development and debug of a COP420; this important benefit facilitates development and debug of a COP420 program prior to masking the final part. The device is also appropriate in low volume applications, or when the program may require changing.

Features

- Extended temperature (-40°C to +85°C) COP302, available as special order
- Low cost
- Exact circuit equivalent of COP420
- Standard 40-pin dual-in-line package
- Interfaces with standard PROM or ROM
- 64 x 4 RAM, addresses up to 1k x 8 ROM
- Powerful instruction set
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 4.0 μs instruction time
- Single supply operation (4.5V to 6.3V)
- Internal time-base counter for real-time processing
- Internal binary counter register with MICROWIRE™ serial I/O capability
- Software/hardware compatible with other members of COP400 family

COP402 and COP302

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at Any Pin	-0.3V to +7V
Operating Temperature Range	0°C to 70°C
COP402-5	0°C to 70°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (soldering, 10 sec.)	300°C

Package Power Dissipation	750 mW at 25°C
	400 mW at 70°C
	250 mW at 85°C

Total Sink Current	50 mA
Total Source Current	70 mA

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

COP402-5

Functional Description

A block diagram of the COP402 is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2V). When a bit is reset, it is a logic "0" (less than 0.8V).

PROGRAM MEMORY

Program Memory consists of a 1,024-byte external memory (typically PROM). Words of this memory may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 16 pages of 64 words each.

ROM addressing is accomplished by a 10-bit PC register. Its binary value selects one of the 1,024 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential **10-bit binary count** value. Three levels of subroutine nesting are implemented by the 10-bit subroutine save registers, SA, SB and SC, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 256-bit RAM, organized as 4 data registers of 16 4-bit digits. RAM addressing is implemented by a 6-bit B register whose upper 2 bits (Br) select 1 of 4 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instruction based upon the 6-bit contents of the operand field of these instructions. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

INTERNAL LOGIC

The 4-bit **A register** (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Br and Bd portions of the B register, to load and input 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A **4-bit adder** performs the arithmetic and logic functions of the COP402, storing its results in A. It also outputs a carry bit to the 1-bit **C register**, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description.)

Four **general-purpose inputs**, IN_3 – IN_0 , are provided; IN_1 , IN_2 , and IN_3 may be selected, by a mask-programmable option, as Read Strobe, Chip Select and Write Strobe inputs, respectively, for use in MICROBUS applications.

The **D register** provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of Bd.

The **G register** contents are outputs to 4 general-purpose bidirectional I/O ports. G_0 may be mask-programmed as a "ready" output for MICROBUS applications.

The **Q register** is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The **8 L drivers**, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M. L I/O ports can be directly connected to the segments of a multiplexed LED display (using the LED Direct Drive output configuration option) with Q data being outputted to the Sa–Sg and decimal point segments of the display.

The **SIO register** functions as a 4-bit serial-in/serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers.

The **XAS instruction** copies C into the SKL latch. In the counter mode, SK is the output of SKL. In the shift register mode, SK outputs SKL ANDed with internal instruction cycle clock.

The **EN register** is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN_3 – EN_0).

1. The least significant bit of the enable register, EN_0 , selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN_0 set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN_3 . With EN_0 reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4.) The SK output becomes a logic-controlled clock.
2. With EN_1 set the IN_1 input is enabled as an interrupt input. Immediately following an interrupt, EN_1 is reset to disable further interrupts.

Functional Description (Continued)

3. With EN_2 set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN_2 disables the L drivers, placing the L I/O ports in a high-impedance input state.
4. EN_3 , in conjunction with EN_0 , affects the SO output. With EN_0 set (binary counter option selected) SO will output the value loaded into EN_3 . With EN_0 reset (serial shift register option selected), setting EN_3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN_3 with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0." The table below provides a summary of the modes associated with EN_3 and EN_0 .

INTERRUPT

The following features are associated with the IN_1 interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- a. The interrupt, once acknowledged as explained below, pushes the next sequential program counter address ($PC + 1$) onto the stack, pushing in turn the contents of the other subroutine-save registers to the next lower level ($PC + 1 \rightarrow SA \rightarrow SB \rightarrow SC$). Any previous contents of SC are lost. The program counter is set to hex address 0FF (the last word of page 3) and EN_1 is reset.
- b. An interrupt will be acknowledged only after the following conditions are met:
 1. EN_1 has been set.
 2. A low-going pulse ("1" to "0") at least two instruction cycles wide occurs on the IN_1 input.
 3. A currently executing instruction has been completed.
 4. All successive transfer of control instructions and successive LBIs have been completed (e.g., if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed).
- c. Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon the popping of the stack. For example, if an interrupt occurs during the execution of ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at hex address 0FF. At the end of the interrupt-routine, a RET instruction is executed to "pop" the stack and return program control to the instruction following the

original ASC. At *this time*, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines and the LQID instruction should not be nested within the interrupt servicing routine since their popping of the stack enables any previously saved main program skips, interfering with the orderly execution of the interrupt routine.

- d. The first instruction of the interrupt routine at hex address 0FF must be a NOP.
- e. An LEI instruction can be put immediately before the RET to re-enable interrupts.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below. The RESET pin is configured as a Schmitt trigger input. If not used it should be connected to V_{CC} . Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least two instruction cycle times.

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, G, and SO are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

$$RC \geq 5 \times \text{Power Supply Rise Time} \quad \text{TL/DD/6915-8}$$

FIGURE 4. Power-Up Clear Circuit

OSCILLATOR

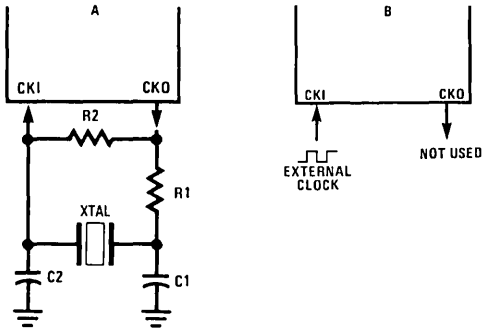

There are two basic clock oscillator configurations available as shown by Figure 5.

- a. **Crystal Controlled Oscillator.** CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 16.
- b. **External Oscillator.** CKI is driven by an external clock signal. The instruction cycle time is the clock frequency divided by 16.

TABLE I. Enable Register Modes—Bits EN_3 and EN_0

EN_3	EN_0	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = SYNC If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = SYNC If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

3.58 MHz	3.3k	1M	22	27
2.09 MHz	8.2k	1M	47	33

FIGURE 5. COP402 Oscillator

EXTERNAL MEMORY INTERFACE

The COP402 is designed for use with an external Program Memory. This memory may be implemented using any devices having the following characteristics:

1. random addressing
2. TTL-compatible TRI-STATE outputs
3. TTL = compatible inputs
4. access time = 1.0 μ s, max.

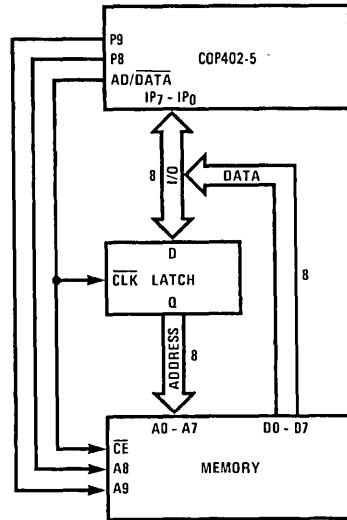

Typically these requirements are met using bipolar or MOS PROMs.

During operation, the address of the next instruction is sent out on P9, P8, and IP7 through IP0 during the time that AD/DAT \bar{A} is high (logic "1" = address mode). Address data on the IP lines is stored into an external latch on the high-to-low transition of the AD/DAT \bar{A} line; P9 and P8 are dedicated address outputs, and do not need to be latched. When AD/DAT \bar{A} is low (logic "0" = data mode), the output of the memory is gated onto IP7 through IP0, forming the input bus. Note that the AD/DAT \bar{A} output has a period of one instruction time, a duty cycle of approximately 50%, and specifies whether the IP lines are used for address output or instruction input. A simplified block diagram of the external memory interface is shown in Figure 6.

INPUT/OUTPUT

COP402 outputs have the following configurations, illustrated in Figure 7.

- a. Standard**—an enhancement-mode device to ground in conjunction with a depletion-mode device to V_{CC}, compatible with TTL and CMOS input requirements.

TL/DD/6915-10

FIGURE 6. External Memory Interface to COP402

- a. High Drive**—same as a. except greater current sourcing capability.
- b. Push-Pull**—an enhancement-mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to V_{CC}. This configuration has been provided to allow for fast rise and fall times when driving capacitive loads.
- c. LED Direct Drive**—an enhancement-mode device to ground and to V_{CC}, meeting the typical current sourcing requirements of the segments of an LED display. These devices may be turned off under program control (see Functional Description, EN Register), placing the outputs in a high-impedance state to provide required LED segment blanking for a multiplexed display.
- d. TRI-STATE Push-Pull**—an enhancement-mode device to ground and V_{CC}. These outputs are TRI-STATE outputs, allowing for connection of these outputs to a data bus shared by other bus drivers.
- f. Input with Load**—Inputs have an on-chip depletion load device to V_{CC}, as shown in Figure 7f.

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of six devices (numbered 1-6, respectively). Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in Figure 7 for each of these devices.

The SO, SK outputs are configured as shown in Figure 7c. The D and G outputs are configured as shown in Figure 7a.

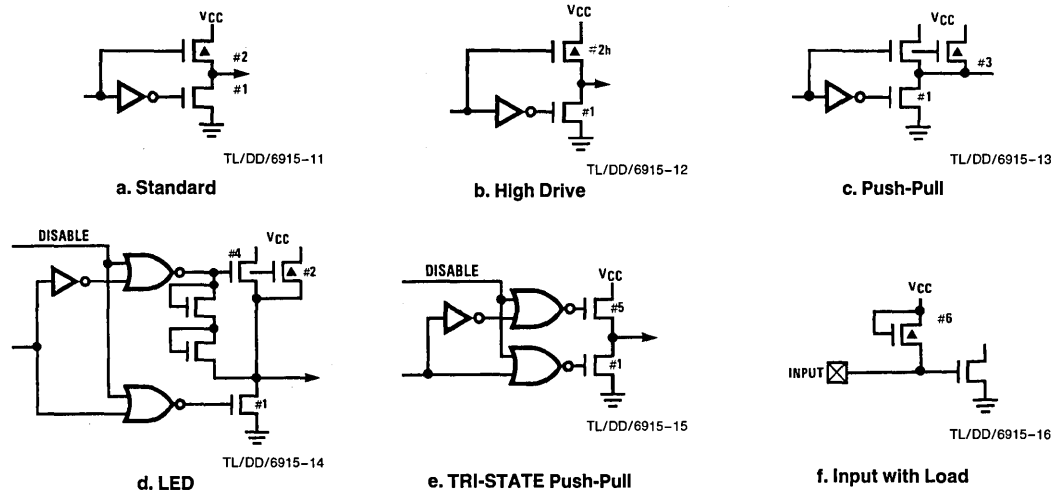

Functional Description (Continued)

Note that when inputting data to the G ports, the G outputs should be set to "1". The L outputs are configured as in Figure 7d on the COP402.

An important point to remember if using configuration d with the L drivers is that even when the L drivers are disabled,

the depletion load device will source a small amount of current. (See Figure 8.)

IP7 through IP0 outputs are configured as shown in Figure 7c; P9, P8, SKIP, and AD/DATA are configured as shown in Figure 8b.

Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code, data flow, skip conditions and description associated with each instruction in the COP402 instruction set.

TABLE II. COP402 Instruction Set Table Symbols

Symbol	Definition	Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS		INSTRUCTION OPERAND SYMBOLS	
A	4-bit Accumulator	d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
B	6-bit RAM Address Register	r	2-bit Operand Field, 0–3 binary (RAM Register Select)
Br	Upper 2 bits of B (register address)	a	9-bit Operand Field, 0–511 binary (ROM Address)
Bd	Lower 4 bits of B (digit address)	y	4-bit Operand Field, 0–15 binary (Immediate Data)
C	1-bit Carry Register	RAM(s)	Contents of RAM location addressed by s
D	4-bit Data Output Port	ROM(t)	Contents of ROM location addressed by t
EN	4-bit Enable Register	OPERATIONAL SYMBOLS	
G	4-bit Register to latch data for G I/O Port	+	Plus
IL	Two 1-bit Latches Associated with the IN ₃ or IN ₀ inputs	–	Minus
IN	4-bit Input port	→	Replaces
L	8-bit TRI-STATE I/O Port	↔	Is exchanged with
M	4-bit contents of RAM Memory pointed to by B Register	=	Is equal to
P	2-bit ROM Address Port	\bar{A}	The one's complement of A
PC	10-bit ROM Address Register (program counter)	⊕	Exclusive-OR
Q	8-bit Register to latch data for L I/O Port	:	Range of values
SA	10-bit Subroutine Save Register A		
SB	10-bit Subroutine Save Register B		
SC	10-bit Subroutine Save Register C		
SIO	4-bit Shift Register and Counter		
SK	Logic-Controlled Clock Output

0100	1111									

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit register.

Note 2: The ININ instruction is not available on the 24-pin COP421 since this device does not contain the IN inputs.

Note 3: For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.

Note 4: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 5: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 6: LBI is a single-byte instruction if d = 0, 9, 10, 11, 12, 13, 14, or 15. The machine code for the lower 4 bits equals the binary value of the "d" data *minus 1*, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 7: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selected Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing programs.

XAS INSTRUCTION

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register.

The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register, above.) If SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

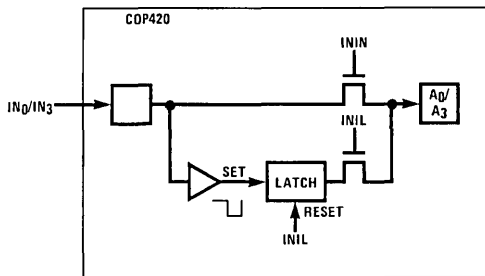

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the contents of ROM addressed by the 10-bit word, PC_{9:8}, A, M. PC₉ and PC₈ are not affected by this instruction.

Note that JID requires 2 instruction cycles.

INIL INSTRUCTION

INIL (Input IL Latches to A) inputs 2 latches, IL₃ and IL₀ (see Figure 9) and CKO into A. The IL₃ and IL₀ latches are set if a low-going pulse ("1" to "0") has occurred on the IN₃ and IN₀ inputs since the last INIL instruction, provided the input pulse stays low for at least two instruction times. Execution of an INIL inputs IL₃ and IN₀ into A₃ and A₀ respectively, and resets these latches to allow them to respond to subsequent low-going pulses on the IN₃ and IN₀ lines. If CKO is mask programmed as a general purpose input, an INIL will input the state of CKO into A₂. If CKO has not been so programmed, a "1" will be placed in A₂. A "0" is always placed in A₁ upon the execution of an INIL. The general purpose inputs IN₃–IN₀ are input to A upon the execution of an ININ instruction. (See Table III, ININ instruction.) INIL is useful in recognizing pulses of short duration or pulses which occur too often to be read conveniently by an ININ instruction.

TL/DD/6915-19

FIGURE 9. IN₀/IN₃ Latches

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 10-bit word PC₉, PC₈, A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB → SC) and replaces the least significant 8 bits of PC as follows: A → PC_{7:4}, RAM(B) → PC_{3:0}, leaving PC₉ and PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SC → SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SB → SC, the previous contents of SC are lost. Also, when LQID pops the stack, the previously pushed contents of SB are left in SC. The net result is that the contents of SB are placed in SC (SB → SC). Note that LQID takes two instruction cycle times to execute.

SKT INSTRUCTION

The SKT (Skip on Timer) instruction tests the state of an internal 10-bit time-base counter. This counter divides the instruction cycle clock frequency by 1024 and provides a latched indication of counter overflow. The SKT instruction tests this latch, executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction, therefore, allow the controller to generate its own time-base for real-time processing rather than relying on an external input signal.

For example, using a 2.097 MHz crystal as the time-base to the clock generator, the instruction cycle clock frequency will be 131 kHz (crystal frequency ÷ 16) and the binary counter output pulse frequency will be 128 Hz. For time-of-day or similar real-time processing, the SKT instruction can call a routine which increments a "seconds" counter every 128 ticks.

INSTRUCTION SET NOTES

- The first word of a program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths take the same number of cycle times whether instructions are skipped or executed, except JID and LQID. LQID and JID take two cycle times if executed and one if skipped.
- The ROM is organized into 16 pages of 64 words each. The Program Counter is a 10-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3, 7, 11, or 15 will access data in the next group of 4 pages.

Typical Application: PROM-Based System

The COP402 may be used to exactly emulate the COP420, *Figure 10* shows the interconnect to implement a COP420 hardware emulation. This connection uses two MM5204 EPROMs as external memory. Other memory can be used such as bipolar PROM or RAM.

Pins IP7-IP0 are bidirectional inputs and outputs. When the AD/DATA clocking output turns on, the EPROM drivers are disabled and IP7-IP0 output addresses. The 8-bit latch (MM74C373) latches the addresses to drive the memory.

When AD/DATA turns off, the EPROMs are enabled and the IP7-IP0 pins will input the memory data. P8 and P9 output the most significant address bits to the memory. (SKIP output may be used for program debug if needed.)

The other 28 pins of the COP402 may be configured exactly the same as a COP420.

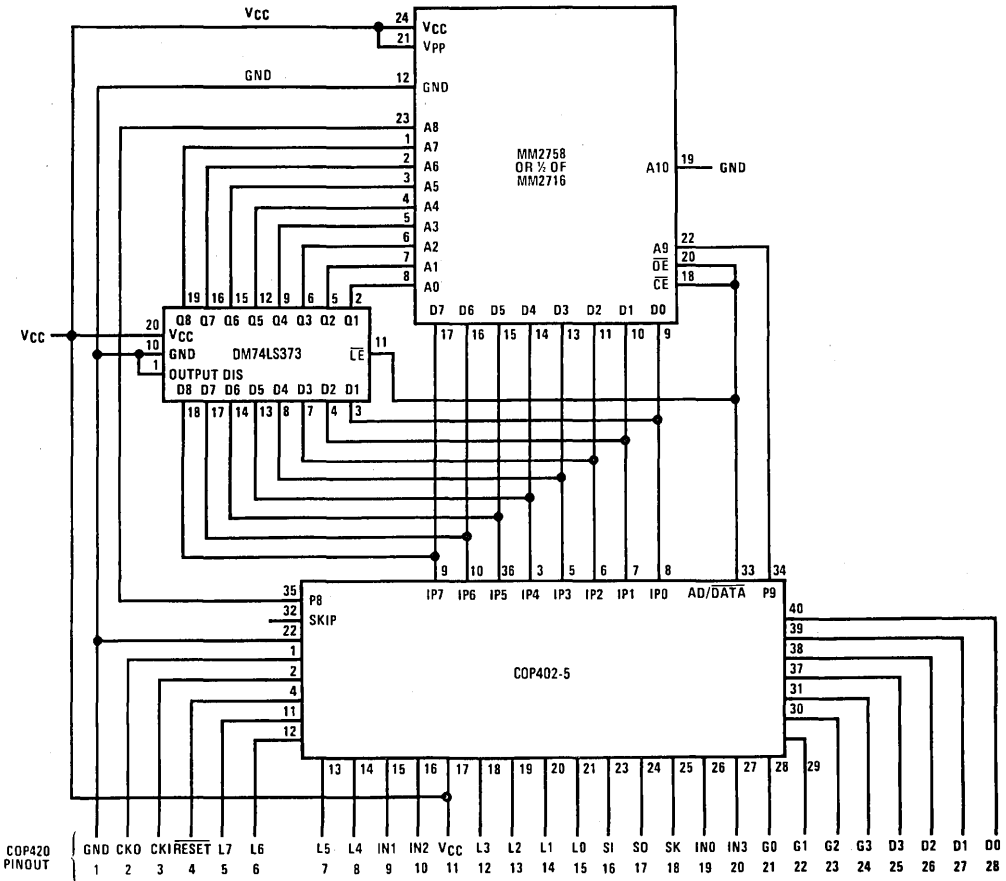

FIGURE 10. COP402 Used to Emulate a COP420

TL/DD/6915-20

Option List

COP402 MASK OPTIONS

The following COP420 options have been implemented in this basic version of the COP402. Subsequent versions of the COP402 will implement different combinations of available options; such versions will be identified as COP402-A, COP402-B, etc.

Option Value	Comment	Option Value	Comment
Option 1 = 0	Ground Pin—no option available	Option 15 = 2, 3	L0 same as L7
Option 2 = 0	CKO is clock generator output to crystal	Option 16 = 0	SI has load device to V_{CC}
Option 3 = 0	CKI is crystal input $\div 16$ (may be overridden externally)	Option 17 = 2	SO has push-pull output
Option 4 = 0	RESET pin has load device to V_{CC}	Option 18 = 2	SK has push-pull output
Option 5 = 2 (402)	L7 has LED direct-drive output	Option 19 = 0	IN0 has load device to V_{CC}
Option 6 = 2, 3	L6 same as L7	Option 20 = 0 (402)	IN3 has load device to V_{CC}
Option 7 = 2, 3	L5 same as L7	Option 21 = 0	G0 has standard output
Option 8 = 2, 3	L4 same as L7	Option 22 = 0	G1 same as G0
Option 9 = 0 (402)	IN1 has load device to V_{CC}	Option 23 = 0	G2 same as G0
Option 10 = 0 (402)	IN2 has load device to V_{CC}	Option 24 = 0	G3 same as G0
Option 11 = 0	V_{CC} pin—no option available	Option 25 = 0	D3 has standard output
Option 12 = 2, 3	L3 same as L7	Option 26 = 0	D2 same as D3
Option 13 = 2, 3	L2 same as L7	Option 27 = 0	D1 same as D3
Option 14 = 2, 3	L1 same as L7	Option 28 = 0	D0 same as D3
		Option 29 = 0 (402)	normal operation
		Option 30 = N/A	40-pin package

COP404C ROMless CMOS Microcontrollers

General Description

The COP404C ROMless Microcontroller is a member of the COPSTM family, fabricated using double-poly, silicon gate CMOS (microCMOS) technology. The COP404C contains CPU, RAM, I/O and is identical to a COP444C device except the ROM has been removed and pins have been added to output the ROM address and to input the ROM data. The COP404C can be configured, by means of external pins, to function as a COP444C, a COP424C, or a COP410C. Pins have been added to allow the user to select the various functional options that are available on the family of mask-programmed CMOS parts. The COP404C is primarily intended for use in the development and debug of a COP program for the COP444C/445C, COP424C/425C, and COP410C/411C devices prior to masking the final part. The COP404C is also appropriate in low volume applications or when the program might be changing.

Features

- Accurate emulation of the COP444C, COP424C and COP410C
- Lowest Power Dissipation (50 μ W typical)
- Fully static (can turn off the clock)
- Power saving IDLE state and HALT mode
- 4 μ s instruction time, plus software selectable clocks
- 128 \times 4 RAM, addresses 2k \times 8 ROM
- True vectored interrupt, plus restart
- Three-level subroutine stack
- Single supply operation (2.4V to 5.5V)
- Programmable read/write 8-bit timer/event counter
- Internal binary counter register with MICROWIRE™ serial I/O capability
- General purpose and TRI-STATE® outputs
- LSTTL/CMOS compatible
- MICROBUS™ compatible
- Software/hardware compatible with other members of the COP400 family

$\overline{SEL10}$	COP410C emulation select input
$\overline{SEL20}$	COP424C emulation select input
UNUSED	Ground

FIGURE 2

The internal architecture is shown in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1", when a bit is reset, it is a logic "0".

PROGRAM MEMORY

Program Memory consists of a 2048-byte external memory (typically PROM). Words of this memory may be program instructions, constants or ROM addressing data.

ROM addressing is accomplished by a 11-bit PC register which selects one of the 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 11-bit binary count value.

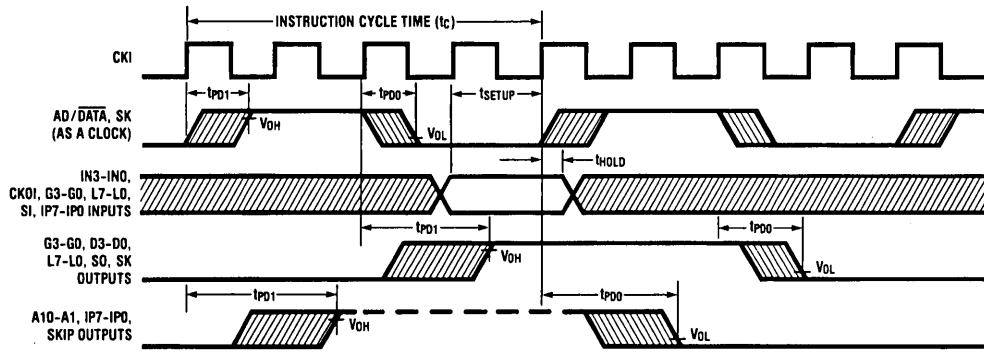

Three levels of subroutine nesting are implemented by a three level deep stack. Each subroutine call or interrupt

pushes the next PC address into the stack. Each return pops the stack back into the PC register.

DATA MEMORY

Data memory consists of a 512-bit RAM, organized as 8 data registers of 16×4 -bit digits. RAM addressing is implemented by a 7-bit B register whose upper 3 bits (B_7) select 1 of 8 data registers and lower 4 bits (B_4) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) are usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or T counter or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instructions based upon the immediate operand field of these instructions. The B_4 register also serves as a source register for 4-bit data sent directly to the D outputs.

Functional Description

INTERNAL LOGIC

The processor contains its own 4-bit A register (accumulator) which is the source and destination register for most I/O, arithmetic, logic, and data memory access operations. It can also be used to load the B_r and B_d portions of the B register, to load and input 4 bits of the 8-bit Q latch or T counter, L I/O ports data, to input 4-bit G, or IN ports, and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions, storing the results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register in conjunction with the XAS instruction and the EN register, also serves to control the SK output.

The 8-bit T counter is a binary up counter which can be loaded to and from M and A using CAMT and CTMA instructions. This counter is operated as a time-base counter. When the T counter overflows, an overflow flag will be set (see SKT and IT instructions below). The T counter is cleared on reset. A functional block diagram of the timer/counter is illustrated in *Figure 10a*.

Four general-purpose inputs, IN₃–IN₀, are provided. IN₁, IN₂ and IN₃ may be selected (by pulling \overline{MB} pin low) as Read Strobe, Chip Select, and Write Strobe inputs, respectively, for use in MICROBUS application.

The D register provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of B_d. In the dual clock mode, DO latch controls the clock selection (see dual oscillator below).

The G register contents are outputs to a 4-bit general-purpose bidirectional I/O port. G₀ may be selected as an output for MICROBUS applications.

The Q register is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are outputted to the L I/O ports when the L drivers are enabled under program control. With the MICROBUS option selected, Q can also be loaded with the 8-bit contents of the L I/O ports upon the occurrence of a write strobe from the host CPU.

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O port. Also, the contents of L may be read directly into A and M. As explained above, the MICROBUS option allows L I/O port data to be latched into the Q register.

The SIO register functions as a 4-bit serial-in/serial-out shift register for MICROWIRE™ I/O and COPS peripherals, or as a binary counter (depending on the contents of the EN register). Its contents can be exchanged with A.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output SKL; in the shift register mode, SK outputs SKL ANDed with the clock.

EN is an internal 4-bit register loaded by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register:

0. The least significant bit of the enable register, EN₀, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, decrementing its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output equals the value of EN₃. With EN₀ reset, SIO is a serial shift register left shifting 1 bit each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. The SK outputs SKL ANDed with the instruction cycle clock.
1. With EN₁ set, interrupt is enabled. Immediately following an interrupt, EN₁ is reset to disable further interrupts.
2. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O port. Resetting EN₂ disables the L drivers, placing the L I/O port in a high-impedance input state.
3. EN₃, in conjunction with EN₀, affects the SO output. With EN₀ set (binary counter option selected) SO will output the value loaded into EN₃. With EN₀ reset (serial shift register option selected), setting EN₃ enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN₃ with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains set to "0".

INTERRUPT

The following features are associated with interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- The interrupt, once recognized as explained below, pushes the next sequential program counter address (PC + 1) onto the stack. Any previous contents at the bottom of the stack are lost. The program counter is set to hex address 0FF (the last word of page 3) and EN₁ is reset.
- An interrupt will be recognized only on the following conditions:
 - EN₁ has been set.
 - A low-going pulse ("1" to "0") at least two instruction cycles wide has occurred on the IN₁ input.
 - A currently executing instruction has been completed.

TABLE I. ENABLE REGISTER MODES — BITS EN₀ AND EN₃

EN ₀	EN ₃	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = clock If SKL = 0, SK = 0
0	1	Shift Register	Input to Shift Register	Serial out	If SKL = 1, SK = clock If SKL = 0, SK = 0
1	0	Binary Counter	Input to Counter	0	SK = SKL
1	1	Binary Counter	Input to Counter	1	SK = SKL

Functional Description (Continued)

4. All successive transfer of control instructions and successive LBIs have been completed (e.g. if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed).
- c. Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon popping of the stack. For example, if an interrupt occurs during the execution of an ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at hex address 0FF. At the end of the interrupt routine, a RET instruction is executed to pop the stack and return program control to the instruction following the original ASC. At this time, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines should not be nested within the interrupt service routine, since their popping of the stack will enable any previously saved main program skips, interfering with the orderly execution of the interrupt routine.
- d. The instruction at hex address 0FF must be a NOP.
- e. An LEI instruction may be put immediately before the RET instruction to re-enable interrupts.

MICROBUS INTERFACE

With \overline{MB} pin tied to Ground, the COP404C can be used as a peripheral microprocessor device, inputting and outputting data from and to a host microprocessor (μ P). IN1, IN2 and IN3 general purpose inputs become MICROBUS compatible read-strobe, chip-select, and write-strobe lines, respectively. IN1 becomes \overline{RD} — a logic "0" on this input will cause Q latch data to be enabled to the L ports for input to the μ P. IN2 becomes \overline{CS} — a logic "0" on this line selects the COP404C and the μ P peripheral device by enabling the operation of the \overline{RD} and \overline{WR} lines and allows for the selection of one of several peripheral components. IN3 becomes \overline{WR} — a logic "0" on this line will write bus data from the L ports to the Q latches for input to the COP404C. G0 becomes INTR a "ready" output, reset by a write pulse from the μ P on the \overline{WR} line, providing the "handshaking" capability necessary for asynchronous data transfer between the host CPU and the COP404C.

This option has been designed for compatibility with National's MICROBUS - a standard interconnect system for 8-bit parallel data transfer between MOS/LSI CPUs and interfacing devices. (See MICROBUS National Publication). The

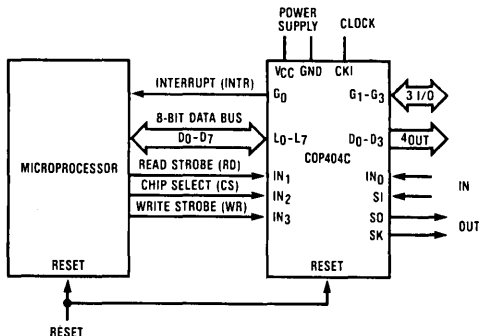

FIGURE 6. MICROBUS Option Interconnect

functioning and timing relationships between the signal lines affected by this option are as specified for the MICROBUS interface, and are given in the AC electrical characteristics and shown in the timing diagrams (Figures 4 and 5). Connection of the COP404C to the MICROBUS is shown in Figure 6.

INITIALIZATION

The external RC network shown in Figure 7 must be connected to the \overline{RESET} pin for the internal reset logic to initialize the device upon power-up. The \overline{RESET} pin is configured as a Schmitt trigger input. If not used, it should be connected to V_{CC} . Initialization will occur whenever a logic "0" is applied to the \overline{RESET} input, providing it stays low for at least three instruction cycle times.

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, IL, T and G registers are cleared. The SKL latch is set, thus enabling SK as a clock output. Data Memory (RAM) is not cleared upon initialization. The first instruction at address 0 must be a CLRA (clear A register).

$RC \geq 5X$ POWER SUPPLY RISE TIME
AND $RC \geq 100X$ CKI PERIOD.

TL/DD/5530-8

FIGURE 7. Power-Up Circuit

TIMER

The timer is operated as a time-base counter. The instruction cycle frequency generated from CKI passes through a 2-bit divide-by-4 prescaler. The output of this prescaler increments the 8-bit T counter thus providing a 10-bit timer. The prescaler is cleared during execution of a CAMT instruction and on reset. For example, using a 1MHz crystal, the instruction cycle frequency of 250 kHz (divide by 4) increments the 10-bit timer every 4 μ S. By presetting the counter and detecting overflow, accurate timeouts between 16 μ S (4 counts) and 4.096 mS (1024 counts) are possible. Longer timeouts can be achieved by accumulating, under software control, multiple overflows.

HALT MODE

The COP404C is a FULLY STATIC circuit; therefore, the user may stop the system oscillator at any time to halt the chip. The chip may also be halted by two other ways (see Figure 8):

- Software HALT: by using the HALT instruction.
- Hardware HALT: by using the HALT I/O port CKOH. It is an I/O flip-flop which is an indicator of the HALT status. An external signal can over-ride this pin to start and stop the chip. By forcing CKOH high the

Functional Description (Continued)

chip will stop as soon as CKI is high and CKOH output will stay high to keep the chip stopped if the external driver returns to high impedance state.

Once in the HALT mode, the internal circuitry does not receive any clock signal and is therefore frozen in the exact state it was in when halted. All information is retained until continuing.

The chip may be awakened by one of two different methods:

- Continue function: by forcing CKOH low, the system clock will be re-enabled and the circuit will continue to operate from the point where it was stopped. CKOH will stay low.
- Restart: by forcing the $\overline{\text{RESET}}$ pin low (see Initialization)

The HALT mode is the minimum power dissipation state.

Note: if the user has selected dual-clock (DUAL pin tied to Ground) AND is forcing an external clock on D0 pin AND the COP404C is running from the D0 clock, the HALT mode - either hardware or software - will NOT be entered. Thus, the user should switch to the CKI clock to HALT. Alternatively, the user may stop the D0 clock to minimize power.

Oscillator Options

There are two basic clock oscillator configurations available as shown by Figure 9.

- CKI oscillator: CKI is configured as a LSTTL compatible input external clock signal. The external frequency is divided by 4 to give the instruction cycle time.
- Dual oscillator. By tying DUAL pin to Ground, pin D0 is now a single pin RC controlled Schmitt trigger oscillator input. The user may software select between the

D0 oscillator (the instruction cycle time equals the D0 oscillation frequency divided by 4) by setting the D0 latch high or the CKI oscillator by resetting D0 latch low.

Note that even in dual clock mode, the counter, if used as a time-base counter, is always connected to the CKI oscillator.

For example, the user may connect up to a 1 MHz RC circuit to D0 for faster processing and a 32 kHz external clock to CKI for minimum current drain and time keeping.

Note: CTMA instruction is not allowed when the chip is running from D0 clock.

Figures 10a and 10b show the timer and clock diagrams with and without Dual-Clock.

TL/DD/5530-9

R	C	Cycle Time	Vcc
15k	82 pF	4-9 μs	≥ 4.5V
30k	82 pF	8-16 μs	≥ 4.5V
60k	100 pF	16-32 μs	2.4-4.5V

Note: $15k \leq R \leq 150k$

$50 \text{ pF} \leq C \leq 150 \text{ pF}$

TL/DD/5530-12

External Memory Interface

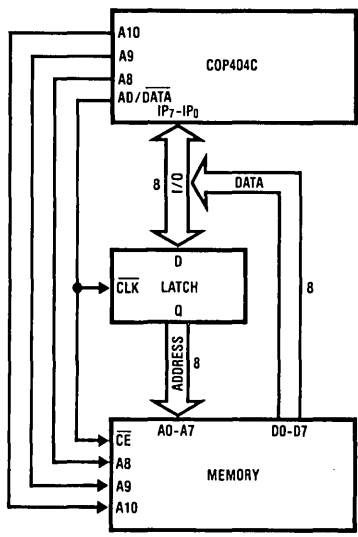

The COP404C is designed for use with an external Program Memory.

This memory may be implemented using any devices having the following characteristics:

1. random addressing
2. LSTTL or CMOS-compatible TRI-STATE outputs
3. LSTTL or CMOS-compatible inputs
4. access time = 1.0 μ s max.

Typically, these requirements are met using bipolar PROMs or MOS/CMOS PROMs, EPROMs or E²PROMs.

During operation, the address of the next instruction is sent out on A10, A9, A8 and IP7 through IP0 during the time that AD/DATA is high (logic "1" = address mode). Address data on the IP lines is stored into an external latch on the high-to-low transition of the AD/DATA line; A10, A9 and A8 are dedicated address outputs, and do not need to be latched. When AD/DATA is low (logic "0" = data mode), the output of the memory is gated onto IP7 through IP0, forming the input bus. Note that AD/DATA output has a period of one instruction time, a duty cycle of approximately 50%, and specifies whether the IP lines are used for address output or data input. A simplified block diagram of the external memory interface is shown in Figure 11.

FIGURE 11. External Memory Interface to COP404C

COP404C Instruction Set

Table II is a symbol table providing internal architecture, instruction operand and operation symbols used in the instruction set table.

Table III provides the mnemonic, operand, machine code data flow, skip conditions and description of each instruction.

Table II. Instruction Set Table Symbols

Symbol	Definition
Internal Architecture Symbols	
A	4-bit Accumulator
B	7-bit RAM address register
Br	Upper 3 bits of B (register address)
Bd	Lower 4 bits of B (digit address)
C	1-bit Carry register
D	4-bit Data output port
EN	4-bit Enable register
G	4-bit General purpose I/O port
IL	two 1-bit (IN0 and IN3) latches
IN	4-bit input port
L	8-bit TRI-STATE I/O port
M	4-bit contents of RAM addressed by B
PC	11-bit ROM address program counter
Q	8-bit latch for L port
SA	11-bit Subroutine Save Register A
SB	11-bit Subroutine Save Register B
SC	11-bit Subroutine Save Register C
SIO	4-bit Shift register and counter
SK	Logic-controlled clock output
SKL	1-bit latch for SK output
T	8-bit timer

Instruction operand symbols

- d 4-bit operand field, 0-15 binary (RAM digit select)
- r 3-bit operand field, 0-7 binary (RAM register select)
- a 11-bit operand field, 0-2047
- y 4-bit operand field, 0-15 (immediate data)

- RAM(x) RAM addressed by variable x
- ROM(x) ROM addressed by variable x

Operational Symbols

- + Plus
- Minus
- > Replaces
- <-> is exchanged with
- = Is equal to
- one's complement of A
- ⊕ exclusive-or
- :

INL		33	0011 0011	L _{7:4} → RAM(B) L _{3:0} → A	None	Input L Ports to RAM,A
		2E	0010 1110			
OBD		33	0011 0011	Bd → D	None	Output Bd to D Outputs
		3E	0011 1110			
OGI	y	33	0011 0011	y → G	None	Output to G Ports Immediate
		5-	0101 y			
OMG		33	0011 0011	RAM(B) → G	None	Output RAM to G Ports
		3A	0011 1010			
XAS		4F	0100 1111	A ↔ SIO, C → SKL	None	Exchange A with SIO (Note 2)

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.

Note 3: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 4: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 5: LBI is a single-byte instruction if d = 0, 9, 10, 11, 12, 13, 14, or 15. The machine code for the lower 4 bits equals the binary value of the "d" data minus 1, e.g., to load the lower four bits of B(Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 6: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds with the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Note 7: If $\overline{\text{SELZ0}} = 1$, A ↔ Br (0 → A3)

If $\overline{\text{SELZ0}} = 0$, A ↔ Br (0,0 → A3, A2).

Description of Selected Instructions

XAS INSTRUCTION

XAS (Exchange A with SIO) copies C to the SKL latch and exchanges the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. If SIO is selected as a shift register, an XAS instruction can be performed once every 4 instruction cycles to effect a continuous data stream.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 11-bit word PC10: PC8, A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB → SC) and replaces the least significant 8 bits of the PC as follows: A → PC (7:4), RAM(B) → PC(3:0), leaving PC(10), PC(9) and PC(8) unchanged. The ROM data pointed to by the

new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SC → SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SB → SC, the previous contents of SC are lost.

Note: LQID uses 2 instruction cycles if executed, one if skipped.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the contents of ROM addressed by the 11-bit word, PC10: B, A, M. PC10, PC9 and PC8 are not affected by JID.

Note: JID uses 2 instruction cycles if executed, one if skipped.

Description of Selected Instructions (Continued)

SKT INSTRUCTION

The SKT (Skip On Timer) instruction tests the state of the T counter overflow latch (see internal logic, above), executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction allow the processor to generate its own time-base for real-time processing, rather than relying on an external input signal.

Note: If the most significant bit of the T counter is a 1 when a CAMT instruction loads the counter, the overflow flag will be set. The following sample of codes should be used when loading the counter:

```
CAMT      ; load T counter
SKT       ; skip if overflow flag is set and reset it
NOP
```

IT INSTRUCTION

The IT (idle till timer) instruction halts the processor and puts it in an idle state until the time-base counter overflows. This idle state reduces current drain since all logic (except the oscillator and time base counter) is stopped.

INIL INSTRUCTION

INIL (Input IL Latches to A) inputs 2 latches, IL3 and IL0, CKOI and 0 into A. The IL3 and IL0 latches are set if a low-going pulse ("1" to "0") has occurred on the IN3 and IN0 inputs since the last INIL instruction, provided the input pulse stays low for at least two instruction cycles. Execution of an INIL inputs IL3 and IL0 into A3 and A0 respectively, and resets these latches to allow them to respond to subsequent low-going pulses on the IN3 and IN0 lines. The state of CKOI is input into A2. A 0 is input into A1. IL latches are cleared on reset.

Instruction Set Notes

- The first word of a program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, they are still fetched from the program memory. Thus program paths take the same number of cycles whether instructions are skipped or executed except for JID, and LQID.
- The ROM is organized into pages of 64 words each. The Program Counter is a 11-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID, or LQID is the last word of a page, it operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a JID or LQID located in the last word of every fourth page (i.e. hex address 0FF, 1FF, 2FF, 3FF, 4FF, etc.) will access data in the next group of four pages.

Power Dissipation

The lowest power drain is when the clock is stopped. As the frequency increases so does current. Current is also lower at lower operating voltages. Therefore, for minimum power dissipation, the user should run at the lowest speed and voltage that his application will allow. The user should take care that all pins swing to full supply levels to insure that outputs are not loaded down and that inputs are not at some intermediate level which may draw current. Any input with a slow rise or fall time will draw additional current. For example, an RC oscillator on D0 will draw more current than a square wave clock input since it is a slow rising signal.

If using an external square wave oscillator, the following equation can be used to calculate the COP404C operating current drain:

$$I_{co} = I_q + V \times 40 \times F_i + V \times 1400 \times F_i / 4$$

where:

I_{co} = chip operating current drain in microamps

I_q = quiescent leakage current (from curve)

F_i = CKI frequency in MegaHertz

V = chip V_{CC} in volts

For example at 5 volts V_{CC} and 400 kHz:

$$I_{co} = 20 + 5 \times 40 \times .4 + 5 \times 1400 \times .4 / 4$$

$$I_{co} = 20 + 80 + 700 = 800 \mu A$$

at 2.4 volts V_{CC} and 30 kHz:

$$I_{co} = 6 + 2.4 \times 40 \times .03 + 2.4 \times 1400 \times .03 / 4$$

$$I_{co} = 6 + 2.88 + 25.2 = 34.08 \mu A$$

If an IT instruction is executed, the chip goes into the IDLE mode until the timer overflows. In IDLE mode, the current drain can be calculated from the following equation:

$$I_{ci} = I_q + V \times 40 \times F_i$$

For example, at 5 volts V_{CC} and 400 kHz

$$I_{ci} = 20 + 5 \times 40 \times .4 = 100 \mu A$$

The total average current will then be the weighted average of the operating current and the idle current:

$$I_{ta} = I_{co} \times \frac{T_o}{T_o + T_i} + I_{ci} \times \frac{T_i}{T_o + T_i}$$

where:

I_{ta} = total average current

I_{co} = operating current

I_{ci} = idle current

T_o = operating time

T_i = idle time

I/O OPTIONS

COP404C outputs have the following configurations, illustrated in *Figure 12*.

- Standard — A CMOS push-pull buffer with an N-channel device to ground in conjunction with a P-channel device to V_{CC} , compatible with CMOS and LSTTL. (Used on SO, SK, AD/DATA, SKIP, A10:8 and D outputs.)
- Low Current — This is the same configuration as a. above except that the sourcing current is much less. (Used on G outputs.)
- Standard TRI-STATE L Output — A CMOS output buffer similar to a. which may be disabled by program control. (Used on L outputs.)

All inputs have the following configuration:

- Input with on chip load device to V_{CC} . (Used on CKOI.)
- Hi-Z input which must be driven by the users logic. (Used on CKI, RESET, IN, SI, DUAL, MB, SELT0 and SEL20 inputs.)

All output drivers use one or more of three common devices numbered 1 to 3. Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 13* for each of these devices to allow the designer to effectively use these I/O configurations.

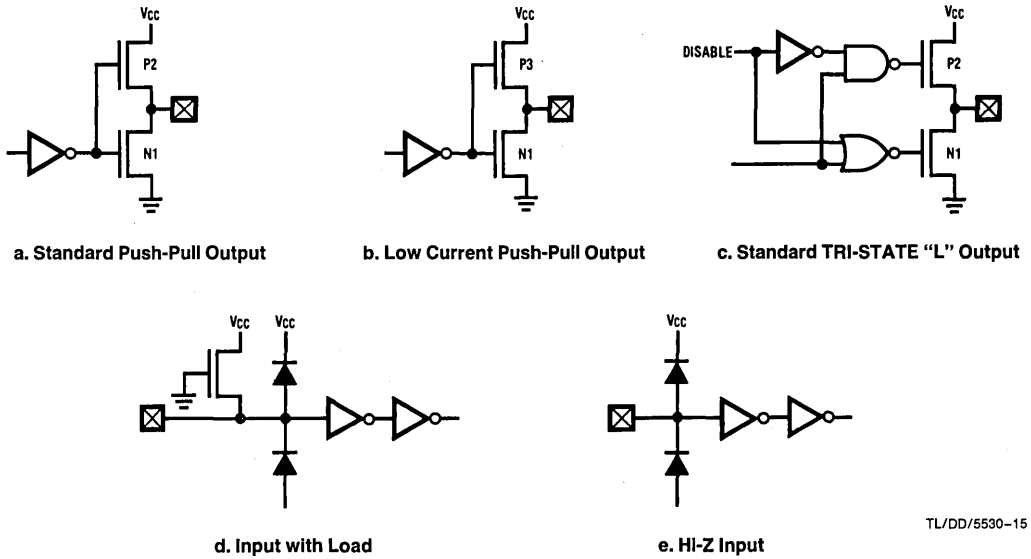

FIGURE 12. Input/Output Configurations

TL/DD/5530-15

Typical Performance Characteristics

FIGURE 13. Input/Output Characteristics

TL/DD/5530-16

Emulation

The COP404C may be used to exactly emulate the COP444C/445C, COP424C/425C, and COP410C/411C. However, the Program Counter always addresses 2k of external ROM whatever chip is being emulated. *Figure 14* shows the interconnect to implement a hardware emulation. This connection uses a NMC27C16 EPROM as external

memory. Other memory can be used such as bipolar PROM or RAM.

Pins IP7-IP0 are bidirectional inputs and outputs. When the AD/DAT \bar{A} clocking output turns on, the EPROM drivers are disabled and IP7-IP0 output addresses. The 8-bit latch (MM74C373) latches the addresses to drive the memory.

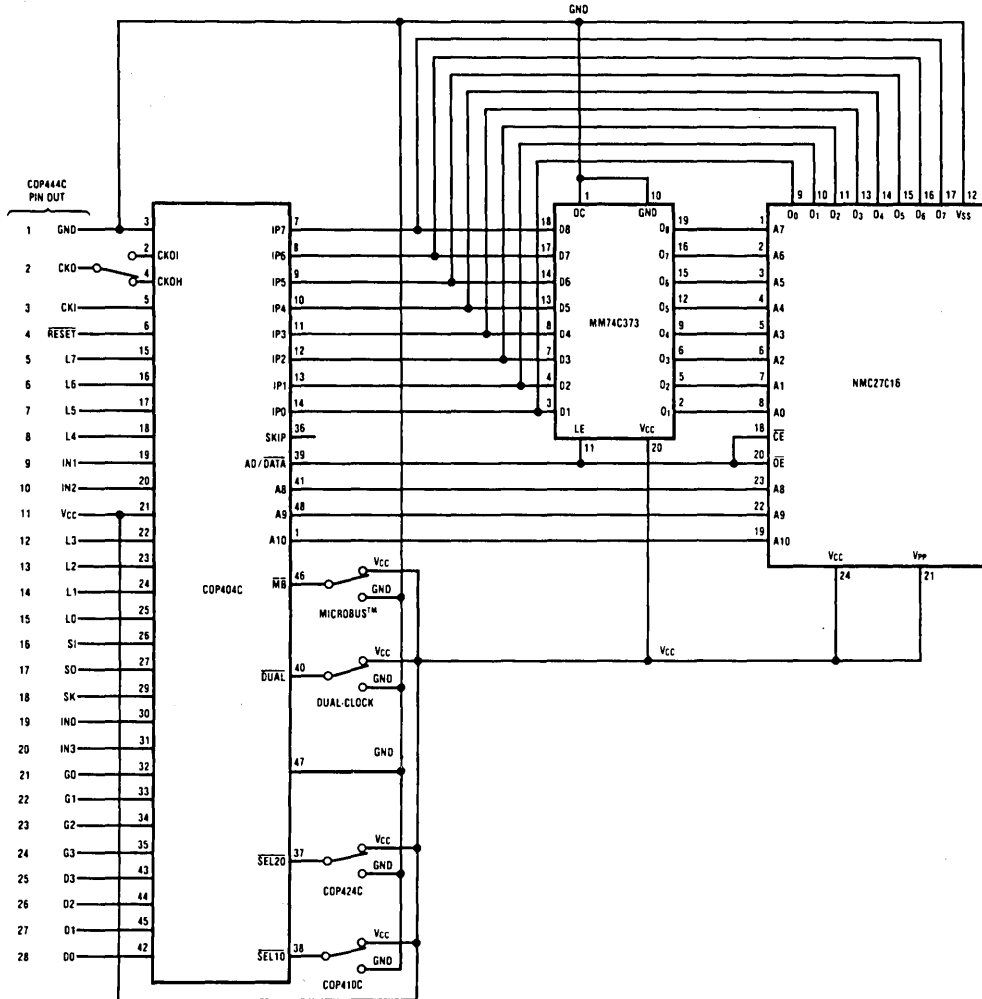

FIGURE 14. COP404C Used To Emulate A COP444C

TL/DD/5530-14

Emulation (Continued)

When AD/DATA turns off, the EPROM is enabled and the IP7-IP0 pins will input the memory data. A10, A9 and A8 output the most significant address bits to the memory. (SKIP output may be used for program debug if needed.)

- CKI is divided by 4. Other divide-by are emulated by external divider.
- CKO can be emulated as a general purpose input by using CKOI or as a Halt I/O port by using CKOH.
- MB pin can be pulled low if the MICROBUS feature of the COP444C and COP424C is needed. Otherwise it should be high.
- DUAL pin can be pulled low if the Dual-Clock feature of the COP444C and COP424C is needed. Otherwise it should be high.
- The SEL10 and SEL20 inputs are used to emulate the COP444C/445C, COP424C/425C, or COP410C/411C.
 - When emulating the COP444C/445C, the user must configure SEL20=1 and SEL10=1.
 - When emulating the COP424C/425C, the user must configure SEL20=0 and SEL10=1. In this mode, the user RAM is physically halved. As in the COP424C/425C, the user has 64 digits (256 bits) of RAM available. Pin A10 should not be connected to the program memory (most significant address bit of the program memory should be grounded if using a 2k×8 memory).
 - When emulating the COP410C/411C, the user must configure SEL20=0 and SEL10=0. In this mode, the user has 32 digits (128 bits) of RAM available organized in the same way as the COP410C/411C - 4 registers of 8 digits each. Pins A10 and A9 should not be connected to the program memory (the 2 most signifi-

cant address bits of the program memory should be grounded).

Furthermore, the subroutine stack is decreased from 3 levels to 2 levels.

The pins SEL10 and SEL20 change the internal logic of the device to accurately emulate the devices as indicated above. However, the user must remember that the COP424C/425C is a subset of the COP444C/COP445C with respect to memory size. The COP410C/411C is a subset both in memory size and in function. The user must take care not to use features and instructions which are not available on the COP410C/411C (see table IV. below) when using the COP404C to emulate the COP410C/411C.

TABLE IV. FEATURES AND INSTRUCTIONS NOT AVAILABLE ON COP410C/411C.

Option Table

COP404C MASK OPTIONS

The following COP444C options have been implemented in the COP404C:

Option value	Comment
Option 1 = 0	Ground Pin — no option available
Option 2 = 1, 2	CKO is replaced by CKOI and CKOH
Option 3 = 5	CKI is external clock input divided by 4
Option 4 = 1	RESET is Hi-Z input
Option 5-8 = 0	L outputs are standard TRI-STATE
Option 9 = 1	IN1 is a Hi-Z input
Option 10 = 1	IN2 is a Hi-Z input
Option 11 = 0	VCC pin — no option available
Option 12-15 = 0	L outputs are standard TRI-STATE
Option 16 = 1	SI is a Hi-Z input
Option 17 = 0	SO is a standard output
Option 18 = 0	SK is a standard output
Option 19 = 1	IN0 is a Hi-Z input
Option 20 = 1	IN3 is a Hi-Z input
Option 21-24 = 1	G outputs are low-current
Option 25-28 = 0	D outputs are standard
Option 29 = 1	No internal initialization logic
Option 30 = 0, 1	DUAL-CLOCK is pin selectable
Option 31 = 0	TIMER time-base counter
Option 32 = 0, 1	MICROBUS is pin selectable
Option 33 = N/A	48-pin package

COP404LSN-5 ROMless N-Channel Microcontrollers

General Description

The COP404LSN-5 ROMless Microcontroller is a member of the COPSM family, fabricated using N-channel, silicon gate MOS technology. The COP404LSN-5 contains CPU, RAM, I/O and is identical to a COP444L device except the ROM has been removed and pins have been added to output the ROM address and to input the ROM data. In a system the COP404LSN-5 will perform exactly as the COP444L. This important benefit facilitates development and debug of a COP program prior to masking the final part. The COP404LSN-5 is also appropriate in low volume applications, or when the program might be changing. The COP404LSN-5 may be used to emulate the COP444L, COP445L, COP420L, and the COP421L.

Use COP404LSN-5 in volume applications. For extended temperature range (-40°C to +85°C), COP304L is available on a special order basis.

Features

- Exact circuit equivalent of COP444L
- Low cost
- Powerful instruction set
- 128 x 4 RAM, addresses 2048 x 8 ROM
- True vectored interrupt, plus restart
- Three-level subroutine stack
- 16 μ s instruction time
- Single supply operation (4.5V-5.5V)
- Low current drain (16 mA max)
- Internal time-base counter for real-time processing
- Internal binary counter register with MICROWIRETM compatible serial I/O
- General purpose outputs
- LSTTL/CMOS compatible in and out
- Direct drive of LED digit and segment lines
- Software/hardware compatible with other members of COP400 family

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Voltage at Any Pin Relative to GND	-0.5V to +10V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	-65°C to +150°C
Lead Temperature (Soldering, 10 sec.)	300°C
Power Dissipation	0.75W at 25°C 0.4W at 70°C

Total Source Current 120 mA

Total Sink Current 140 mA

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics

4.5V ≤ V_{CC} ≤ 5.5V; 0°C ≤ T_A ≤ 70°C

Parameter	Conditions	Min	Max	Units
Operating Voltage (V _{CC})		4.5	5.5	V

Pin Descriptions

Pin	Description
L7-L0	8 bidirectional I/O ports with TRI-STATE®
G3-G0	4 bidirectional I/O ports
D3-D0	4 general purpose outputs
IN3-IN0	4 general purpose outputs
SI	Serial input (or counter input)
SO	Serial output (or general purpose output)
SK	Logic-controlled clock (or general purpose output)
AD/DATA	Address out/data in flag
CKI	System oscillator input
CKO	System oscillator output (COP404LSN-5)
RESET	System reset input
VCC	Power supply
GND	Ground
IP7-IP0	8 bidirectional ROM address and data ports
P8, P9	2 ROM address outputs
SKIP/P10	Instruction skip output and most significant ROM address bit output

Functional Description

A block diagram of the COP404LSN-5 is given in *Figure 1*. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device. Positive logic is used. When a bit is set, it is a logic "1" (greater than 2V). When a bit is reset, it is a logic "0" (less than 0.8V).

PROGRAM MEMORY

Program Memory consists of a 2048 byte external memory. As can be seen by an examination of the COP404LSN-5 instruction set, these words may be program instructions, program data or ROM addressing data. Because of the special characteristics associated with the JP, JSRP, JID and LQID instructions, ROM must often be thought of as being organized into 32 pages of 64 words each.

ROM addressing is accomplished by an 11-bit PC register. Its binary value selects one of the 2048 8-bit words contained in ROM. A new address is loaded into the PC register during each instruction cycle. Unless the instruction is a transfer of control instruction, the PC register is loaded with the next sequential 11-bit binary count value. Three levels of subroutine nesting are implemented by the 11-bit subroutine saves registers, SA, SB, and SC, providing a last-in, first-out (LIFO) hardware subroutine stack.

ROM instruction words are fetched, decoded and executed by the Instruction Decode, Control and Skip Logic circuitry.

DATA MEMORY

Data memory consists of a 512-bit RAM, organized as 8 data registers of 16 4-bit digits. RAM addressing is implemented by a 7-bit B register whose upper 3 bits (Br) select 1 of 8 data registers and lower 4 bits (Bd) select 1 of 16 4-bit digits in the selected data register. While the 4-bit contents of the selected RAM digit (M) is usually loaded into or from, or exchanged with, the A register (accumulator), it may also be loaded into or from the Q latches or loaded from the L ports. RAM addressing may also be performed directly by the LDD and XAD instructions based upon the 7-bit contents of the operand field of these instructions. The Bd register also serves as a source register for 4-bit data sent directly to the D outputs.

INTERNAL LOGIC

The 4-bit A register (accumulator) is the source and destination register for most I/O, arithmetic, logic and data memory access operations. It can also be used to load the Br and Bd portions of the B register, to load and input 4 bits of the 8-bit Q latch data, to input 4 bits of the 8-bit L I/O port data and to perform data exchanges with the SIO register.

A 4-bit adder performs the arithmetic and logic functions, storing its results in A. It also outputs a carry bit to the 1-bit C register, most often employed to indicate arithmetic overflow. The C register, in conjunction with the XAS instruction and the EN register, also serves to control the SK output. C can be outputted directly to SK or can enable SK to be a sync clock each instruction cycle time. (See XAS instruction and EN register description, below).

Four general-purpose inputs, IN₃–IN₀, are provided.

The D register provides 4 general-purpose outputs and is used as the destination register for the 4-bit contents of Bd. The D outputs can be directly connected to the digits of a multiplexed LED display.

The G register contents are outputs to 4 general-purpose bidirectional I/O ports. G I/O ports can be directly connected to the digits of a multiplexed LED display.

The Q register is an internal, latched, 8-bit register, used to hold data loaded to or from M and A, as well as 8-bit data from ROM. Its contents are output to the L I/O ports when the L drivers are enabled under program control. (See LEI instruction.)

The 8 L drivers, when enabled, output the contents of latched Q data to the L I/O ports. Also, the contents of L may be read directly into A and M. L I/O ports can be directly connected to the segments of a multiplexed LED display (using the LED Direct Drive output configuration option) with Q data being outputted to the Sa–Sg and decimal point segments of the display.

The SIO register functions as a 4-bit serial-in/serial-out shift register or as a binary counter depending on the contents of the EN register. (See EN register description, below.) Its contents can be exchanged with A, allowing it to input or output a continuous serial data stream. SIO may also be used to provide additional parallel I/O by connecting SO to external serial-in/parallel-out shift registers.

The XAS instruction copies C into the SKL latch. In the counter mode, SK is the output of SKL; in the shift register mode, SK outputs SKL ANDed with the clock.

The EN register is an internal 4-bit register loaded under program control by the LEI instruction. The state of each bit of this register selects or deselects the particular feature associated with each bit of the EN register (EN₃–EN₀).

1. The least significant bit of the enable register, EN₀, selects the SIO register as either a 4-bit shift register or a 4-bit binary counter. With EN₀ set, SIO is an asynchronous binary counter, *decrementing* its value by one upon each low-going pulse ("1" to "0") occurring on the SI input. Each pulse must be at least two instruction cycles wide. SK outputs the value of SKL. The SO output is equal to the value of EN₃. With EN₀ reset, SIO is a serial shift register shifting left each instruction cycle time. The data present at SI goes into the least significant bit of SIO. SO can be enabled to output the most significant bit of SIO each cycle time. (See 4 below.) The SK output becomes a logic-controlled clock.
2. With EN₁ set the IN₁ input is enabled as an interrupt input. Immediately following an interrupt, EN₁ is reset to disable further interrupts.
3. With EN₂ set, the L drivers are enabled to output the data in Q to the L I/O ports. Resetting EN₂ disables the L drivers, placing the L I/O ports in a high-impedance input state.

Functional Description (Continued)

4. EN_3 , in conjunction with EN_0 , affects the SO output. With EN_0 set (binary counter option selected) SO will output the value loaded into EN_3 . With EN_0 reset (serial shift register option selected), setting EN_3 enables SO as the output of the SIO shift register, outputting serial shifted data each instruction time. Resetting EN_3 with the serial shift register option selected disables SO as the shift register output; data continues to be shifted through SIO and can be exchanged with A via an XAS instruction but SO remains reset to "0." The table below provides a summary of the modes associated with EN_3 and EN_0 .

INTERRUPT

The following features are associated with the IN_1 interrupt procedure and protocol and must be considered by the programmer when utilizing interrupts.

- The interrupt, once acknowledged as explained below, pushes the next sequential program counter address ($PC+1$) onto the stack, pushing in turn the contents of the other subroutine-save registers to the next lower level ($PC+1 \rightarrow SA \rightarrow SB \rightarrow SC$). Any previous contents of SC are lost. The program counter is set to hex address OFF (the last word of page 3) and EN_1 is reset.
- An interrupt will be acknowledged only after the following conditions are met:
 - EN_1 has been set.
 - A low-going pulse ("1" to "0") at least two instruction cycles wide occurs on the IN_1 input.
 - A currently executing instruction has been completed.
 - All successive transfer of control instructions and successive LBIs have been completed (e.g., if the main program is executing a JP instruction which transfers program control to another JP instruction, the interrupt will not be acknowledged until the second JP instruction has been executed).
- Upon acknowledgement of an interrupt, the skip logic status is saved and later restored upon popping of the stack. For example, if an interrupt occurs during the execution of ASC (Add with Carry, Skip on Carry) instruction which results in carry, the skip logic status is saved and program control is transferred to the interrupt servicing routine at hex address OFF. At the end of the interrupt routine, a RET instruction is executed to "pop" the stack and return program control to the instruction following the original ASC. At this time, the skip logic is enabled and skips this instruction because of the previous ASC carry. Subroutines and LQID instructions should not be nested within the interrupt service routine, since their popping the stack will enable any previously saved main program skips, interfering with the orderly execution of the interrupt routine.

- The first instruction of the interrupt routine at hex address OFF must be a NOP.
- A LEI instruction can be put immediately before the RET to re-enable interrupts.

INITIALIZATION

The Reset Logic will initialize (clear) the device upon power-up if the power supply rise time is less than 1 ms and greater than 1 μ s. If the power supply rise time is greater than 1 ms, the user must provide an external RC network and diode to the RESET pin as shown below. The RESET pin is configured as a Schmitt trigger input. If the RC network is not used, the RESET pin should be left open. Initialization will occur whenever a logic "0" is applied to the RESET input, provided it stays low for at least three instruction cycle times.

TL/DD/8817-4

$$RC \geq 5 \times \text{Power Supply Rise Time (R} > 40k)$$

Upon initialization, the PC register is cleared to 0 (ROM address 0) and the A, B, C, D, EN, and G registers are cleared. The SK output is enabled as a SYNC output, providing a pulse each instruction cycle time. *Data Memory (RAM) is not cleared upon initialization.* The first instruction at address 0 must be a CLRA.

EXTERNAL MEMORY INTERFACE

The COP404LSN-5 is designed for use with an external Program Memory. This memory may be implemented using any devices having the following characteristics:

- random addressing
- TTL-compatible TRI-STATE outputs
- TTL-compatible inputs
- access time = 5 μ s max.

Typically these requirements are met using bipolar or MOS PROMs.

During operation, the address of the next instruction is sent out on P10, P9, P8, and IP7 through IP0 during the time that $\overline{AD/DATA}$ is high (logic "1" = address mode). Address data on the IP lines is stored into an external latch on the high-to-low transition of the $\overline{AD/DATA}$ line; P9 and P8 are

Enable Register Modes — Bits EN_3 and EN_0

EN_3	EN_0	SIO	SI	SO	SK
0	0	Shift Register	Input to Shift Register	0	If SKL = 1, SK = CLOCK If SKL = 0, SK = 0
1	0	Shift Register	Input to Shift Register	Serial Out	If SKL = 1, SK = CLOCK If SKL = 0, SK = 0
0	1	Binary Counter	Input to Binary Counter	0	If SKL = 1, SK = 1 If SKL = 0, SK = 0
1	1	Binary Counter	Input to Binary Counter	1	If SKL = 1, SK = 1 If SKL = 0, SK = 0

Functional Description (Continued)

dedicated address outputs, and do not need to be latched. SKIP/P10 outputs address data when AD/DATA is low. When AD/DATA is low (logic "0" = data mode), the output of the memory is gated onto IP7 through IP0, forming the input bus. Note that the AD/DATA output has a period of one instruction time, a duty cycle of approximately 50%, and specifies whether the IP lines are used for address output or instruction input.

OSCILLATOR

The basic clock oscillator configurations is shown in *Figure 4*.

Crystal Controlled Oscillator—CKI and CKO are connected to an external crystal. The instruction cycle time equals the crystal frequency divided by 32.

TL/DD/8817-5

FIGURE 4. Oscillator

INPUT/OUTPUT CONFIGURATIONS

COP404LSN-5 outputs have the following configurations, illustrated in *Figure 5*:

a. Standard—an enhancement mode device to ground in conjunction with a depletion-mode device to VCC, compatible with LSTTL and CMOS input requirements. (Used on D and G outputs.)

TL/DD/8817-6

a. Standard Output

TL/DD/8817-7

b. Open-Drain Output

TL/DD/8817-8

c. Push-Pull Output

TL/DD/8817-9

d. L Output (LED)

TL/DD/8817-10

e. Input with Load

(Δ is Depletion Device)

FIGURE 5. Output Configurations

b. Open-Drain—an enhancement-mode device to ground only, allowing external pull-up as required by the user's application.

c. Push-Pull—an enhancement-mode device to ground in conjunction with a depletion-mode device paralleled by an enhancement-mode device to VCC. This configuration has been provided to allow for fast rise and fall times when driving capacitive loads.

d. LED Direct Drive—an enhancement-mode device to ground and to VCC, meeting the typical current sourcing requirements of the segments of an LED display. The sourcing device is clamped to limit current flow. These devices may be turned off under program control (see Functional Description, EN Register), placing the outputs in a high-impedance state to provide required LED segment blanking for a multiplexed display. (Used on L outputs.)

COP404LSN-5 inputs have an on-chip depletion load device to VCC.

The above input and output configurations share common enhancement-mode and depletion-mode devices. Specifically, all configurations use one or more of six devices (numbered 1–6, respectively). Minimum and maximum current (I_{OUT} and V_{OUT}) curves are given in *Figure 6* for each of these devices to allow the designer to effectively use these I/O configurations in designing a system.

An important point to remember is that even when the L drivers are disabled, the depletion load device will source a small amount of current (see *Figure 6*, device 2); however, when the L-lines are used as inputs, the disabled depletion device can *not* be relied on to source sufficient current to pull an input to a logic "1".

Typical Performance Characteristics

FIGURE 6. COP404LSN-5 I/O Characteristics

COP404LSN-5 Instruction Set

Table I is a symbol table providing internal architecture, instruction operand and operational symbols used in the instruction set table.

Table II provides the mnemonic, operand, machine code, data flow, skip conditions, and description associated with each instruction in the COP404LSN-5 instruction set.

TABLE I. COP404LSN-5 Instruction Set Table Symbols

Symbol	Definition	Symbol	Definition
INTERNAL ARCHITECTURE SYMBOLS		INSTRUCTION OPERAND SYMBOLS	
A	4-bit Accumulator	d	4-bit Operand Field, 0–15 binary (RAM Digit Select)
B	10-bit RAM Address Register	r	3-bit Operand Field, 0–7 binary (RAM Register Select)
Br	Upper 3 bits of B (register address)	a	11-bit Operand Field, 0–2047 binary (ROM Address)
Bd	Lower 4 bits of B (digit address)	y	4-bit Operand Field, 0–15 binary (Immediate Data)
C	1-bit Carry Register	RAM(s)	Contents of RAM location addressed by s
D	4-bit Data Output Port	ROM(t)	Contents of ROM location addressed by t
EN	4-bit Enable Register		
G	4-bit Register to latch data for G I/O Port	OPERATIONAL SYMBOLS	
IL	Two 1-bit latches associated with the IN ₃ or IN ₀ inputs	+	Plus
IN	4-bit Input Port	–	Minus
IP	8-bit bidirectional ROM address and Data Port	→	Replaces
L	8-bit TRI-STATE I/O Port	↔	Is exchanged with
M	4-bit contents of RAM Memory pointed to by B Register	=	Is equal to
P	3-bit ROM Address Register Port	\bar{A}	The one's complement of A
PC	11-bit ROM Address Register (program counter)	⊕	Exclusive-OR
Q	8-bit Register to latch data for L I/O Port	:	Range of values
SA	11-bit Subroutine Save Register A		
SB	11-bit Subroutine Save Register B		
SC	11-bit Subroutine Save Register C		
SIO	4-bit Shift Register and Counter		
SK	Logic-Controlled Clock Output

OMG		33 3A	<table border="1"><tr><td>0011</td><td>0011</td></tr><tr><td>0011</td><td>1010</td></tr></table>	0011	0011	0011	1010	$RAM(B) \rightarrow G$	None	Output RAM to G Ports
0011	0011									
0011	1010									
XAS		4F	<table border="1"><tr><td>0100</td><td>1111</td></tr></table>	0100	1111	$A \leftrightarrow SIO, C \rightarrow SKL$	None	Exchange A with SIO (Note 2)		
0100	1111									

Note 1: All subscripts for alphabetical symbols indicate bit numbers unless explicitly defined (e.g., Br and Bd are explicitly defined). Bits are numbered 0 to N where 0 signifies the least significant bit (low-order, right-most bit). For example, A₃ indicates the most significant (left-most) bit of the 4-bit A register.

Note 2: For additional information on the operation of the XAS, JID, LQID, INIL, and SKT instructions, see below.

Note 3: The JP instruction allows a jump, while in subroutine pages 2 or 3, to any ROM location within the two-page boundary of pages 2 or 3. The JP instruction, otherwise, permits a jump to a ROM location within the current 64-word page. JP may not jump to the last word of a page.

Note 4: A JSRP transfers program control to subroutine page 2 (0010 is loaded into the upper 4 bits of P). A JSRP may not be used when in pages 2 or 3. JSRP may not jump to the last word in page 2.

Note 5: LBI is a single-byte instruction if $d = 0, 9, 10, 11, 12, 13, 14,$ or 15 . The machine code for the lower 4 bits equals the binary value of the "d" data *minus 1*, e.g., to load the lower four bits of B (Bd) with the value 9 (1001₂), the lower 4 bits of the LBI instruction equal 8 (1000₂). To load 0, the lower 4 bits of the LBI instruction should equal 15 (1111₂).

Note 6: Machine code for operand field y for LEI instruction should equal the binary value to be latched into EN, where a "1" or "0" in each bit of EN corresponds to the selection or deselection of a particular function associated with each bit. (See Functional Description, EN Register.)

Description of Selection Instructions

The following information is provided to assist the user in understanding the operation of several unique instructions and to provide notes useful to programmers in writing COP404LSN-5 programs.

XAS INSTRUCTIONS

XAS (Exchange A with SIO) exchanges the 4-bit contents of the accumulator with the 4-bit contents of the SIO register. The contents of SIO will contain serial-in/serial-out shift register or binary counter data, depending on the value of the EN register. An XAS instruction will also affect the SK output. (See Functional Description, EN Register.) If SIO is selected as a shift register, an XAS instruction must be performed once every 4 instruction cycles to effect a continuous data stream.

JID INSTRUCTION

JID (Jump Indirect) is an indirect addressing instruction, transferring program control to a new ROM location pointed to indirectly by A and M. It loads the lower 8 bits of the ROM address register PC with the *contents* of ROM addressed by the 11-bit word, PC_{10:8}, A, M. PC₁₀, PC₉ and PC₈ are not affected by this instruction.

Note: JID requires 2 instruction cycles to execute.

INIL INSTRUCTION

INIL (Input IL Latches to A) inputs 2 latches, IL₃ and IL₀ (see Figure 7) and CKO into A. The IL₃ and IL₀ latches are set if a low-going pulse ("1" to "0") has occurred on the IN₃ and IN₀ inputs since the last INIL instruction, provided the input pulse stays low for at least two instruction times. Execution of an INIL inputs IL₃ and IL₀ into A₃ and A₀ respectively, and resets these latches to allow them to respond to subsequent low-going pulses on the IN₃ and IN₀ lines. INIL will input "1" into A₂ on the COP404LSN-5. A "0" is always placed in A₁ upon the execution of an INIL. The general purpose inputs IN₃-IN₀ are input to A upon execution of an ININ instruction. (See Table II, ININ instruction.) INIL is use-

ful in recognizing pulses of short duration or pulses which occur too often to be read conveniently by an ININ instruction.

Note: IL latches are not cleared on reset.

LQID INSTRUCTION

LQID (Load Q Indirect) loads the 8-bit Q register with the contents of ROM pointed to by the 11-bit word PC₁₀, PC₉, PC₈, A, M. LQID can be used for table lookup or code conversion such as BCD to seven-segment. The LQID instruction "pushes" the stack (PC + 1 → SA → SB → SC) and replaces the least significant 8 bits of PC as follows: A → PC_{7:4}, RAM(B) → PC_{3:0}, leaving PC₁₀, PC₉ and PC₈ unchanged. The ROM data pointed to by the new address is fetched and loaded into the Q latches. Next, the stack is "popped" (SC → SB → SA → PC), restoring the saved value of PC to continue sequential program execution. Since LQID pushes SB → SC, the previous contents of SC are lost. Also, when LQID pops the stack, the previously pushed contents of SB are left in SC. The net result is that the contents of SB are placed in SC (SB → SC).

Note: LQID takes two instruction cycle times to execute.

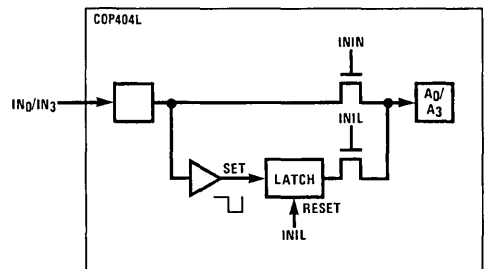

FIGURE 7. INIL Hardware Implementation

TL/DD/8617-12

Description of Selected Instructions (Continued)

SKT INSTRUCTION

The SKT (Skip On Timer) instruction tests the state of an internal 10-bit time-base counter. This counter divides the instruction cycle clock frequency by 1024 and provides a latched indication of counter overflow. The SKT instruction tests this latch, executing the next program instruction if the latch is not set. If the latch has been set since the previous test, the next program instruction is skipped and the latch is reset. The features associated with this instruction, therefore, allow the COP404LSN-5 to generate its own time-base for real-time processing rather than relying on an external input signal.

For example, using a 2.097 MHz oscillator as the time-base to the clock generator, the instruction cycle clock frequency will be 65 kHz (crystal frequency \div 32) and the binary counter output pulse frequency will be 64 Hz. For time-of-day or similar real-time processing, the SKT instruction can call a routine which increments a "seconds" counter every 64 ticks.

INSTRUCTION SET NOTES

- The first word of a COP404LSN-5 program (ROM address 0) must be a CLRA (Clear A) instruction.
- Although skipped instructions are not executed, one instruction cycle time is devoted to skipping each byte of the skipped instruction. Thus all program paths except JID and LQID take the same number of cycle times whether instructions are skipped or executed. JID and LQID instructions take 2 cycles if executed and 1 cycle if skipped.

- The ROM is organized into 32 pages of 64 words each. The Program Counter is an 11-bit binary counter, and will count through page boundaries. If a JP, JSRP, JID or LQID instruction is located in the last word of a page, the instruction operates as if it were in the next page. For example: a JP located in the last word of a page will jump to a location in the next page. Also, a LQID or JID located in the last word of page 3, 7, 11, 15, 19, 23 or 27 will access data in the next group of four pages.

Typical Applications

PROM-BASED SYSTEM

The COP404LSN-5 may be used to exactly emulate the COP444L. *Figure 8* shows the interconnect to implement a COP444L hardware emulation. This connection uses a MM2716 EPROM as external memory. Other memory can be used such as bipolar PROM or RAM.

Pins IP7–IP0 are bidirectional inputs and outputs. When the AD/DAT \bar{A} clocking output turns on, the EPROM drivers are disabled and IP7–IP0 output addresses. The 8-bit latch (MM74LS373) latches the addresses to drive the memory.

When AD/DAT \bar{A} turns off, the EPROM is enabled and the IP7–IP0 pins will input the memory data. P8, P9 and SKIP/P10 output the most significant address bits to the memory. (SKIP output may be used for program debug if needed.)

The other 28 pins of the COP404LSN-5 may be configured exactly the same as a COP444L. The COP404LSN-5 V_{CC} can vary from 4.5V to 5.5V. However, 5V is used for the memory.

For In-Circuit emulation, see also COP444LP.

COP404LSN-5 Mask Options

The following COP444L options have been implemented on the COP404LSN-5.

Option Value	Comment	Option Value	Comment
Option 1 = 0	Ground, no option available	Option 18 = 2	SK has push-pull output
Option 2 = 0	CKO is clock generator output to crystal/resonator	Option 19 = 0	IN0 has load device to V_{CC}
Option 3 = 0	CKI is oscillator input (divide by 32)	Option 20 = 0	IN3 has load device to V_{CC}
Option 4 = 0	\overline{RESET} pin has load device to V_{CC}	Option 21 = 0	G ₀ } have high current
Option 5 = 2	L ₇ } have LED direct-drive	Option 22 = 0	G ₁ } standard output
Option 6 = 2	L ₆ } output	Option 23 = 0	G ₂ }
Option 7 = 2	L ₅ }	Option 24 = 0	G ₃ }
Option 8 = 2	L ₄ }	Option 25 = 0	D ₃ } have high current
Option 9 = 0	IN1 has load device to V_{CC}	Option 26 = 0	D ₂ }
Option 10 = 0	IN2 has load device to V_{CC}	Option 27 = 0	D ₁ } standard output
Option 11 = 1	V_{CC} 4.5V to 5.5V operation	Option 28 = 0	D ₀ }
Option 12 = 2	L ₃ } have LED direct-drive	Option 29 = 1	L } have higher voltage
Option 13 = 2	L ₂ } output	Option 30 = 1	IN } input levels
Option 14 = 2	L ₁ }	Option 31 = 1	G } SI has standard input level
Option 15 = 2	L ₀ }	Option 32 = 0	\overline{RESET} has Schmitt trigger input
Option 16 = 0	SI has load to V_{CC}	Option 33 = 0	CKO has standard input levels
Option 17 = 2	SO has push-pull output	Option 34 = 0	40-pin package
		Option 35 = N/A	

Typical Applications (Continued)

COP420P/COP444CP/COP444LP Piggyback EPROM Microcontrollers

General Description

The COP420P, COP444CP, and COP444LP are piggyback versions of the COPSM microcontroller families. These devices are identical to their respective device except the program ROM has been removed. The device package incorporates the circuitry and socket on top of package to accommodate the piggyback EPROM—MM2716, NMC27C16 or other appropriate EPROMs. With the addition of an EPROM, the device performs exactly as its masked equivalent.

The device is a complete microcontroller system with CPU, RAM, I/O and EPROM socket in a 28-lead package. The completed package allows field test of the system in the final electrical and mechanical configuration. This important benefit facilitates development and debug of the COP400 program prior to masking of a production part.

These devices are also economical in low and medium volume applications or when the program may require changing.

Device Selection	Device Emulated	Piggyback Device
Low Power NMOS	COP420L, COP444L	COP444LP
High Speed NMOS	COP420	COP420P
Low Power CMOS	COP424C, COP444C	COP444CP

Features

COP444LP

- 16 μ s instruction time
- Same Specification as COP404LSN-5

COP420P

- 4 μ s instruction time
- Same Specification as COP402N

COP444CP

- 4 μ s instruction time
- Fully static (can turn off clock)
- Power-saving IDLE state and Halt mode
- Same Specification as COP404C

TL/DD/8705-10

COP420P Absolute Maximum Ratings

Voltage at Any Pin	-0.3V to +7V
Operating Temperature Range COP420P	0°C to 70°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (Soldering, 10 sec.)	300°C
Total Sink Current	50 mA
Total Source Current	70 mA

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

COP420P DC Electrical Characteristics

Sink (Note 6)	$V_{CC} = 4.5V, V_{OUT} = V_{CC}$	1.2		mA
Source (Standard Option)	$V_{CC} = 4.5V, V_{OUT} = 0V$	0.5		mA
Source (Low Current Option)	$V_{CC} = 4.5V, V_{OUT} = 0V$	30	330	μA
Allowable Sink/Source Current Per Pin (Note 4)			5	mA
Allowable Loading on CKOH			100	pF
Current Needed to Over-Ride HALT (Note 3)				
To Continue	$V_{CC} = 4.5V, V_{IN} = 2 V_{CC}$		0.7	mA
To Halt	$V_{CC} = 4.5V, V_{IN} = 7 V_{CC}$		1.6	mA
TRI-STATE Leakage Current		-2.5	+2.5	μA

COP444CP AC Electrical Characteristics0°C < T_A < 70°C, 4.5V ≤ V_{CC} ≤ 5.5V unless otherwise specified

Parameter	Conditions	Min	Max	Units
Instruction Cycle Time (t _C)	V _{CC} ≥ 4.5V	4	DC	μs
Operating CKI Frequency	V _{CC} ≥ 4.5V	DC	1.0	MHz
Inputs				
t _{SETUP}	G Inputs }	t _C /4 + 0.7		μs
	SI Input } V _{CC} ≥ 4.5V	0.3		μs
	IP Input }	1.0		μs
	All Others }	1.7		μs
t _{CLOCK}	V _{CC} ≥ 4.5V	0.25		μs
Output Propagation Delay	V _{OUT} = 1.5V, C _L = 100 pF, R _L = 5k			
IP7–IP0, A10–A8, SKIP				
t _(pd1) , T _(pd0)	V _{CC} ≥ 4.5V		1.94	μs
AD/DATA				
t _(pd1) , t _(pd0)	V _{CC} ≥ 4.5V		375	μs
All Other Outputs				
t _(pd1) , t _(pd0)	V _{CC} > 4.5V		1.0	μs

Note 1: Supply current is measured after running for 2000 cycle times with a square-wave clock on CKI and all other pins pulled up to V_{CC} with 20k resistors.

Note 2: When forcing HALT, current is only needed for a short time (approx. 200 ns) to flip the HALT flip-flop.

Note 3: Voltage change must be less than 0.5V in a 1 ms period.

Note 4: SO output sink current must be limited to keep V_{OL} less than 0.2 V_{CC} (i.e., 0.1 mA at 2.4V V_{CC} and 0.5 mA at 4.5V V_{CC}).

COP444LP Absolute Maximum Ratings

Voltage at Any Pin Relative to GND	-0.5V to +10V
Ambient Operating Temperature	0°C to +70°C
Ambient Storage Temperature	-65°C to +150°C
Lead Temperature (Soldering, 10 sec.)	300°C
Power Dissipation	0.75W at 25°C 0.4W at 70°C

Total Source Current	120 mA
Total Sink Current	140 mA

Note: *Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.*

COP420 (COP444LP) Mask Options

The following COP420 (COP444L) options have been implemented in the COP420P (COP444LP):

Option Value	Comment
Option 1 = 0	GND pin—no option available
Option 2 = 0	CKO is clock generator output to crystal
Option 3 = 0	CKI is crystal input ÷ 16 (÷ 32 COP444LP)
Option 4 = 0	RESET pin has load device to V _{CC}
Option 5–8 = 2	L outputs have LED direct-drive
Option 9 = 0	IN1 has load device to V _{CC}
Option 10 = 0	IN2 has load device to V _{CC}
Option 11 = 0 (COP420P)	V _{CC} pin—no option available
(Option 11 = 1 COP444LP)	V _{CC} pin—4.5V–5.5V operation
Option 12–15 = 2	L outputs have LED direct-drive
Option 16 = 0	SI has load device to V _{CC}
Option 17 = 2	SO has push-pull output
Option 18 = 2	SK has push-pull output
Option 19 = 0	IN0 has load device to V _{CC}
Option 20 = 0	IN3 has load device to V _{CC}
Option 21–24 = 0	G outputs are standard (COP420P). G outputs have very high current standard output (COP444LP)
Option 25–28 = 0	D outputs are standard (COP420P). D outputs have very high current standard output (COP444LP)
Option 29 = 0 (COP420P)	Normal operation
(Option 29 = 1 COP444LP)	L has higher voltage input levels
Option 30 = 0 (COP420P)	28-pin package
(Option 30 = 1 COP444LP)	IN has higher voltage input levels
Option 31 = 0 (COP420P)	IN has standard input levels
(Option 31 = 1 COP444LP)	G has higher voltage input levels
Option 32 = 0	G has standard input levels (COP420P). SI has standard input levels (COP444LP)
Option 33 = 0	L has standard input levels (COP420P). RESET has Schmitt trigger input (COP444LP)
Option 34 = 0	No option
Option 35 = 0	SI has standard input levels (COP420P). 28-pin package (COP444LP)

COP444CP Mask Options

The following COP444C options have been implemented in the COP444CP:

Option Value	Comment
Option 1 = 0	GND pin—no option available
Option 2 = 1	CKO is HALT I/O
Option 3 = 5	CKI is external clock input ÷ 4
Option 4 = 1	RESET is Hi-Z input
Option 5–8 = 0	L outputs are standard TRI-STATE
Option 9 = 1	IN1 is a Hi-Z input
Option 10 = 1	IN2 is a Hi-Z input
Option 11 = 0	V _{CC} pin (4.5V–5.5V)
Option 12–15 = 0	L outputs are standard TRI-STATE
Option 16 = 1	SI is a Hi-Z input
Option 17 = 0	SO is a standard output
Option 18 = 0	SK is a standard output
Option 19 = 1	IN0 is a Hi-Z input
Option 20 = 1	IN3 is a Hi-Z input
Option 21–24 = 1	G outputs are low current
Option 25–28 = 0	D outputs are standard
Option 29 = 1	No internal initialization logic
Option 30 = 0	Normal operation
Option 31 = 0	Time-base counter
Option 32 = 0	Normal
Option 33 = 0	28-pin package

Note: The COP404C die used for the COP444CP is configured to support 2K ROM, 128 x 4 RAM, D0 as a normal output, and CKO as the HALT restart.

The 8-Bit COP800 Family: Optimized for Value

National's COP800 family provides cost-effective solutions for feature-rich, 8-bit microcontroller applications.

Key Features

- High-performance 8-bit microcontroller
- Full 8-bit architecture and implementation
- 1 μ s instruction-cycle time
- High code efficiency with single-byte, multiple-function instructions
- UART
- A/D converter
- WATCHDOG™/clock monitor
- Brown Out Detect
- On-chip ROM from 1 kbyte
- On-chip RAM to 192 bytes
- EEPROM
- M²C^{MOS}™ fabrication
- MICROWIRE/PLUS™ serial interface
- ROMless versions available
- Wide operating voltage range: +2.5V to +6V
- Military temp range available: -55°C to +125°C
- MIL-STD-883C versions available
- 20- to 44-pin packages

The COP800 combines a powerful single-byte, multiple-function instruction set with a memory-mapped core architecture similar to the HPC™.

And like the HPC, the COP800 family supports a wide variety of ROM, RAM, I/O and peripheral functions.

The COP800 has an instruction-cycle time of only 1 μ s, and because over 70% of its instruction set is composed of single-cycle, single-byte instructions, the COP800 can deliver exceptional performance for an 8-bit engine.

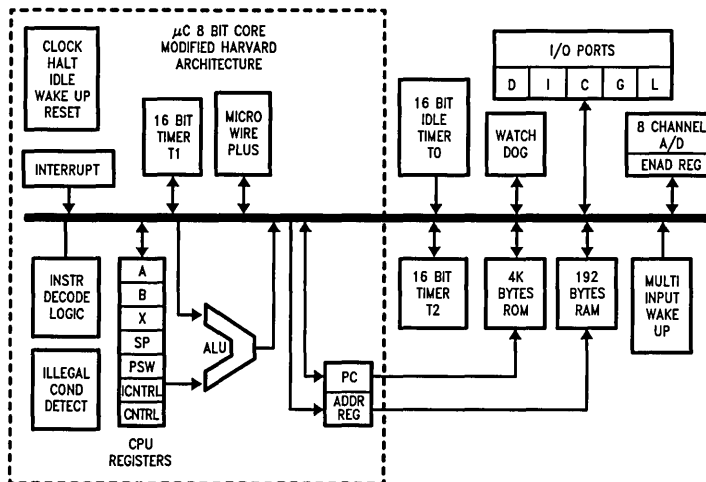

And since it's fabricated in National's advanced M²C^{MOS} process, the COP800 has low current drain, low heat dissipation, and a wide operating voltage range.

Key Applications

- Automotive systems
- Process control
- Robotics
- Telecommunications
- AC-motor control
- DC-motor control
- Keyboard controllers
- Modems
- RS232C controllers

The COP800 family offers high performance in a low-cost, easy-to-design-in package.

General Description

The COP820C and COP840C are members of the COPSTM microcontroller family. They are fully static parts, fabricated using double-metal silicon gate microCMOS technology. This low cost microcontroller is a complete microcomputer containing all system timing, interrupt logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS™ serial I/O, a 16-bit timer/counter with capture register and a multi-sourced interrupt. Each I/O pin has software selectable options to adapt the COP820C and COP840C to the specific application. The part operates over a voltage range of 2.5 to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a 1 microsecond per instruction rate.

Features

- Low Cost 8-bit microcontroller
- Fully static CMOS
- 1 μ s instruction time (10 MHz clock)
- Low current drain (2.2 mA at 3 μ s instruction rate)
Low current static HALT mode (Typically < 1 μ A)
- Single supply operation: 2.5 to 6.0V
- 1024 bytes ROM/64 Bytes RAM—COP820C
- 2048 bytes ROM/128 Bytes RAM—COP840C
- 16-bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - Reset master clear
 - External interrupt with selectable edge
 - Timer interrupt or capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set, most instructions single byte
- BCD arithmetic instructions
- MICROWIRE/PLUS serial I/O
- 28 pin package (optionally 20 pin package)
- 24 input/output pins (28-pin package)
- Software selectable I/O options (TRI-STATE®, push-pull, weak pull-up)
- Schmitt trigger inputs on Port G
- Temperature ranges: 0°C to +70°C, -40°C to +85°C, -55°C to +125°C
- Form Factor emulation devices
- Fully supported by National's development system

COP920C/COP922C/COP940C/COP942C**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC}) 7V
 Voltage at any Pin $-0.3V$ to $V_{CC} + 0.3V$
 Total Current into V_{CC} Pin (Source) 50 mA

Total Current out of GND Pin (Sink) 60 mA
 Storage Temperature Range $-65^{\circ}C$ to $+140^{\circ}C$

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics COP92XC, COP94XC; $0^{\circ}C \leq T_A \leq +70^{\circ}C$ unless otherwise specified

Parameter	Condition	Min	Typ	Max	Units
Operating Voltage COP9XXC		2.3		4.0	V
COP9XXCH		4.0		6.0	V
Power Supply Ripple (Note 1)	Peak to Peak			$0.1 V_{CC}$	V
Supply Current (Note 2)					
CKI = 10 MHz	$V_{CC} = 6V, t_c = 1 \mu s$			7.5	mA

Input Capacitance				7	pF
Load Capacitance on D2				1000	pF

COP920C/COP922C/COP940C/COP942C**DC Electrical Characteristics** (Continued)

Note 1: Rate of voltage change must be less than 0.5V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L and G ports TRI-STATE and tied to ground, all outputs low and tied to ground.

Note 4: Except pin G7: +100 mA, -25 mA (COP920C only). Sampled and not 100% tested. Pins G6 and $\overline{\text{RESET}}$ are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

AC Electrical Characteristics 0°C < T_A < +70°C unless otherwise specified

Parameter	Condition	Min	Typ	Max	Units
Instruction Cycle Time (t_c) Ext., Crystal/Resonator (Div-by 10)	$V_{CC} \geq 4.0V$ $2.3V \leq V_{CC} \leq 4.0V$	1 2.5		DC DC	μs μs

FIGURE 3

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

RESET is the master reset input. See Reset description.

PORT I is a four bit Hi-Z input port.

PORT L is an 8-bit I/O port.

There are two registers associated with each L I/O port: a data register and a configuration register. Therefore, each L I/O bit can be individually configured under software control as shown below:

Port L Config.	Port L Data	Port L Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input With Weak Pull-Up
1	0	Push-Pull "0" Output
1	1	Push-Pull "1" Output

Three data memory address locations are allocated for these ports, one for data register, one for configuration register and one for the input pins.

PORT G is an 8-bit port with 6 I/O pins (G0–G5) and 2 input pins (G6, G7). All eight G-pins have Schmitt Triggers on the inputs. The G7 pin functions as an input pin under normal operation and as the continue pin to exit the HALT mode. There are two registers with each I/O port: a data register and a configuration register. Therefore, each I/O bit can be individually configured under software control as shown below.

Port G Config.	Port G Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input With Weak Pull-Up
1	0	Push-Pull "0" Output
1	1	Push-Pull "1" Output

Three data memory address locations are allocated for these ports, one for data register, one for configuration register and one for the input pins. Since G6 and G7 are input only pins, any attempt by the user to set them up as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. Note that the chip will be placed in the HALT mode by setting the G7 data bit.

Six bits of Port G have alternate features:

- G0 INTR (an external interrupt)
- G3 TIO (timer/counter input/output)
- G4 SO (MICROWIRE serial data output)
- G5 SK (MICROWIRE clock I/O)
- G6 SI (MICROWIRE serial data input)
- G7 CKO crystal oscillator output (selected by mask option) or HALT restart input (general purpose input)

Pins G1 and G2 currently do not have any alternate functions.

PORT D is a four bit output port that is set high when **RESET** goes low.

Functional Description

Figure 1 shows the block diagram of the internal architecture. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device.

ALU AND CPU REGISTERS

The ALU can do an 8-bit addition, subtraction, logical or shift operation in one cycle time.

There are five CPU registers:

A is the 8-bit Accumulator register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is the 8-bit address register, can be auto incremented or decremented.

X is the 8-bit alternate address register, can be incremented or decremented.

SP is the 8-bit stack pointer, points to subroutine stack (in RAM).

B, X and SP registers are mapped into the on chip RAM. The B and X registers are used to address the on chip RAM. The SP register is used to address the stack in RAM during subroutine calls and returns.

PROGRAM MEMORY

Program memory for the COP820C consists of 1024 bytes of ROM (2048 bytes of ROM for the COP840C). These bytes may hold program instructions or constant data. The program memory is addressed by the 15-bit program counter (PC). ROM can be indirectly read by the LAID instruction for table lookup.

DATA MEMORY

The data memory address space includes on chip RAM, I/O and registers. Data memory is addressed directly by the instruction or indirectly by the B, X and SP registers.

The COP820C has 64 bytes of RAM and the COP840C has 128 bytes of RAM. Sixteen bytes of RAM are mapped as "registers" that can be loaded immediately, decremented or tested. Three specific registers: B, X and SP are mapped into this space, the other bytes are available for general usage.

The instruction set permits any bit in memory to be set, reset or tested. All I/O and registers (except the A & PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested.

RESET

The **RESET** input when pulled low initializes the microcontroller. Initialization will occur whenever the **RESET** input is pulled low. Upon initialization, the ports L and G are placed in the TRI-STATE mode and the Port D is set high. The PC, PSW and CNTRL registers are cleared. The data and configuration registers for Ports L & G are cleared.

The external RC network shown in Figure 4 should be used to ensure that the **RESET** pin is held low until the power supply to the chip stabilizes.

FIGURE 4. Recommended Reset Circuit

OSCILLATOR CIRCUITS

Figure 5 shows the three clock oscillator configurations available for the COP820C and COP840C.

A. CRYSTAL OSCILLATOR

The COP820C/COP840C can be driven by a crystal clock. The crystal network is connected between the pins CKI and CKO.

Table I shows the component values required for various standard crystal values.

B. EXTERNAL OSCILLATOR

CKI can be driven by an external clock signal. CKO is available as a general purpose input and/or HALT restart control.

C. R/C OSCILLATOR

CKI is configured as a single pin RC controlled Schmitt trigger oscillator. CKO is available as a general purpose input and/or HALT restart control.

Table II shows the variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/9103-10

FIGURE 5. Crystal and R-C Connection Diagrams

OSCILLATOR MASK OPTIONS

The COP820C and COP840C can be driven by clock inputs between DC and 10 MHz.

TABLE I. Crystal Oscillator Configuration, $T_A = 25^\circ\text{C}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)	Conditions
0	1	30	30-36	10	$V_{CC} = 5V$
0	1	30	30-36	4	$V_{CC} = 5V$
0	1	200	100-150	0.455	$V_{CC} = 5V$

TABLE II. RC Oscillator Configuration, $T_A = 25^\circ\text{C}$

R (k Ω)	C (pF)	CKI Freq. (MHz)	Instr. Cycle (μs)	Conditions
3.3	82	2.2 to 2.7	3.7 to 4.6	$V_{CC} = 5V$
5.6	100	1.1 to 1.3	7.4 to 9.0	$V_{CC} = 5V$
6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5V$

Note: $3k \leq R \leq 200k$, $50 \text{ pF} \leq C \leq 200 \text{ pF}$

Functional Description (Continued)

The COP820C and COP840C microcontrollers have three mask options for configuring the clock input. The CKI and CKO pins are automatically configured upon selecting a particular option.

- Crystal (CKI/10) CKO for crystal configuration
- External (CKI/10) CKO available as G7 input
- R/C (CKI/10) CKO available as G7 input

G7 can be used either as a general purpose input or as a control input to continue from the HALT mode.

CURRENT DRAIN

The total current drain of the chip depends on:

- 1) Oscillator operating mode—I1
- 2) Internal switching current—I2
- 3) Internal leakage current—I3
- 4) Output source current—I4
- 5) DC current caused by external input not at V_{CC} or GND—I5

Thus the total current drain, It is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5$$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw the least current when in the normal mode. The high speed mode will draw additional current. The R/C mode will draw the most. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

Where

C = equivalent capacitance of the chip.

V = operating voltage

f = CKI frequency

HALT MODE

The COP820C and COP840C support a power saving mode of operation: HALT. The controller is placed in the HALT mode by setting the G7 data bit, alternatively the user can stop the clock input. In the HALT mode all internal processor activities including the clock oscillator are stopped. The fully static architecture freezes the state of the controller and retains all information until continuing. In the HALT mode, power requirements are minimal as it draws only leakage currents and output current. The applied voltage (V_{CC}) may be decreased down to V_r (minimum RAM retention voltage) without altering the state of the machine.

There are two ways to exit the HALT mode: via the \overline{RESET} or by the CKO pin. A low on the \overline{RESET} line reinitializes the microcontroller and starts executing from the address

0000H. A low to high transition on the CKO pin causes the microcontroller to continue with no reinitialization from the address following the HALT instruction. This also resets the G7 data bit.

INTERRUPTS

The COP820C and COP840C have a sophisticated interrupt structure to allow easy interface to the real world. There are three possible interrupt sources, as shown below.

A maskable interrupt on external G0 input (positive or negative edge sensitive under software control)

A maskable interrupt on timer underflow or timer capture

A non-maskable software/error interrupt on opcode zero

INTERRUPT CONTROL

The GIE (global interrupt enable) bit enables the interrupt function. This is used in conjunction with ENI and ENTI to select one or both of the interrupt sources. This bit is reset when interrupt is acknowledged.

ENI and ENTI bits select external and timer interrupt respectively. Thus the user can select either or both sources to interrupt the microcontroller when GIE is enabled.

IEDG selects the external interrupt edge (0 = rising edge, 1 = falling edge). The user can get an interrupt on both rising and falling edges by toggling the state of IEDG bit after each interrupt.

IPND and TPND bits signal which interrupt is pending. After interrupt is acknowledged, the user can check these two bits to determine which interrupt is pending. This permits the interrupts to be prioritized under software. The pending flags have to be cleared by the user. Setting the GIE bit high inside the interrupt subroutine allows nested interrupts.

The software interrupt does not reset the GIE bit. This means that the controller can be interrupted by other interrupt sources while servicing the software interrupt.

INTERRUPT PROCESSING

The interrupt, once acknowledged, pushes the program counter (PC) onto the stack and the stack pointer (SP) is decremented twice. The Global Interrupt Enable (GIE) bit is reset to disable further interrupts. The microcontroller then vectors to the address 00FFH and resumes execution from that address. This process takes 7 cycles to complete. At the end of the interrupt subroutine, any of the following three instructions return the processor back to the main program: RET, RETSK or RETI. Either one of the three instructions will pop the stack into the program counter (PC). The stack pointer is then incremented twice. The RETI instruction additionally sets the GIE bit to re-enable further interrupts.

Any of the three instructions can be used to return from a hardware interrupt subroutine. The RETSK instruction should be used when returning from a software interrupt subroutine to avoid entering an infinite loop.

Functional Description (Continued)

FIGURE 6. Interrupt Block Diagram

TL/DD/9103-11

DETECTION OF ILLEGAL CONDITIONS

The COP820C and COP840C incorporate a hardware mechanism that allows it to detect illegal conditions which may occur from coding errors, noise and 'brown out' voltage drop situations. Specifically it detects cases of executing out of undefined ROM area and unbalanced stack situations.

Reading an undefined ROM location returns 00 (hexadecimal) as its contents. The opcode for a software interrupt is also '00'. Thus a program accessing undefined ROM will cause a software interrupt.

Reading an undefined RAM location returns an FF (hexadecimal). The subroutine stack on the COP820C and COP840C grows down for each subroutine call. By initializing the stack pointer to the top of RAM, the first unbalanced return instruction will cause the stack pointer to address undefined RAM. As a result the program will attempt to execute from FFFF (hexadecimal), which is an undefined ROM location and will trigger a software interrupt.

MICROWIRE/PLUS™

MICROWIRE/PLUS is a serial synchronous bidirectional communications interface. The MICROWIRE/PLUS capability enables the COP820C and COP840C to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, EEPROMS, etc.) and with other microcontrollers which support the MICROWIRE/PLUS interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 7 shows the block diagram of the MICROWIRE/PLUS interface.

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS interface with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE/PLUS interface with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. The SK clock rate is selected by the two bits, S0 and S1, in the CNTRL register. Table III details the different clock rates that may be selected.

TABLE III

S1	S0	SK Cycle Time
0	0	2t _C
0	1	4t _C
1	x	8t _C

where,

t_C is the instruction cycle clock.

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS arrangement to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. The COP820C and COP840C may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. Figure 8 shows how two COP820C microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangement.

Master MICROWIRE/PLUS Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the COP820C. The MICROWIRE/PLUS Master always initiates all data exchanges. (See Figure 8). The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The S0 and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table IV summarizes the bit settings required for Master mode of operation.

SLAVE MICROWIRE/PLUS OPERATION

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by appropriately setting up the Port G configuration register. Table IV summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated. (See Figure 8.)

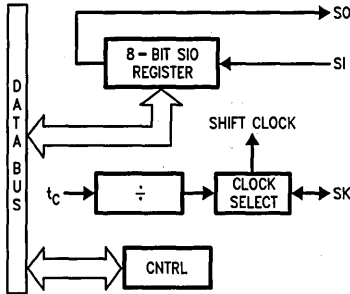

Functional Description (Continued)

TIMER/COUNTER

The COP820C and COP840C have a powerful 16-bit timer with an associated 16-bit register enabling them to perform extensive timer functions. The timer T1 and its register R1 are each organized as two 8-bit read/write registers. Control bits in the register CNTRL allow the timer to be started and stopped under software control. The timer-register pair can be operated in one of three possible modes. Table V details various timer operating modes and their requisite control settings.

TL/DD/9103-12

FIGURE 7. MICROWIRE/PLUS Block Diagram

MODE 1. TIMER WITH AUTO-LOAD REGISTER

In this mode of operation, the timer T1 counts down at the instruction cycle rate. Upon underflow the value in the register R1 gets automatically reloaded into the timer which continues to count down. The timer underflow can be programmed to interrupt the microcontroller. A bit in the control register CNTRL enables the TIO (G3) pin to toggle upon timer underflows. This allows the generation of square-wave outputs or pulse width modulated outputs under software control. (See Figure 9)

MODE 2. EXTERNAL COUNTER

In this mode, the timer T1 becomes a 16-bit external event counter. The counter counts down upon an edge on the TIO pin. Control bits in the register CNTRL program the counter to decrement either on a positive edge or on a negative edge. Upon underflow the contents of the register R1 are automatically copied into the counter. The underflow can also be programmed to generate an interrupt. (See Figure 9)

MODE 3. TIMER WITH CAPTURE REGISTER

Timer T1 can be used to precisely measure external frequencies or events in this mode of operation. The timer T1 counts down at the instruction cycle rate. Upon the occurrence of a specified edge on the TIO pin the contents of the timer T1 are copied into the register R1. Bits in the control register CNTRL allow the trigger edge to be specified either as a positive edge or as a negative edge. In this mode the user can elect to be interrupted on the specified trigger edge. (See Figure 10.)

FIGURE 8. MICROWIRE/PLUS Application

Functional Description (Continued)

TABLE V. Timer Operating Modes

CNTRL Bits 7 6 5	Operation Mode	T Interrupt	Timer Counts On
0 0 0	External Counter W/Auto-Load Reg.	Timer Carry	TIO Pos. Edge
0 0 1	External Counter W/Auto-Load Reg.	Timer Carry	TIO Neg. Edge
0 1 0	Not Allowed	Not Allowed	Not Allowed
0 1 1	Not Allowed	Not Allowed	Not Allowed
1 0 0	Timer W/Auto-Load Reg.	Timer Carry	t_c
1 0 1	Timer W/Auto-Load Reg./Toggle TIO Out	Timer Carry	t_c
1 1 0	Timer W/Capture Register	TIO Pos. Edge	t_c
1 1 1	Timer W/Capture Register	TIO Neg. Edge	t_c

FIGURE 9. Timer/Counter Auto Reload Mode Block Diagram

TL/DD/9103-15

TIMER PWM APPLICATION

Figure 11 shows how a minimal component D/A converter can be built out of the Timer-Register pair in the Auto-Reload mode. The timer is placed in the "Timer with auto reload" mode and the TIO pin is selected as the timer output. At the outset the TIO pin is set high, the timer T1 holds the on time and the register R1 holds the signal off time. Setting TRUN bit starts the timer which counts down at the instruction cycle rate. The underflow toggles the TIO output and copies the off time into the timer, which continues to run. By alternately loading in the on time and the off time at each successive interrupt a PWM frequency can be easily generated.

Control Registers

CNTRL REGISTER (ADDRESS X'00EE)

The Timer and MICROWIRE/PLUS control register contains the following bits:

- S1 & S0 Select the MICROWIRE/PLUS clock divide-by
 IEDG External interrupt edge polarity select
 (0 = rising edge, 1 = falling edge)
 MSEL Enable MICROWIRE/PLUS functions SO and SK
 TRUN Start/Stop the Timer/Counter (1 = run, 0 = stop)
 TC3 Timer input edge polarity select (0 = rising edge, 1 = falling edge)
 TC2 Selects the capture mode
 TC1 Selects the timer mode

TC1	TC2	TC3	TRUN	MSEL	IEDG	S1	S0
						BIT 7	BIT 0

PSW REGISTER (ADDRESS X'00EF)

The PSW register contains the following select bits:

- GIE Global interrupt enable
 ENI External interrupt enable
 BUSY MICROWIRE/PLUS busy shifting
 IPND External interrupt pending
 ENTI Timer interrupt enable
 TPND Timer interrupt pending
 C Carry Flag
 HC Half carry Flag

HC	C	TPND	ENTI	IPND	BUSY	ENI	GIE
						Bit 7	Bit 0

Addressing Modes

REGISTER INDIRECT

This is the "normal" mode of addressing for COP820C and COP840C. The operand is the memory addressed by the B register or X register.

DIRECT

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

IMMEDIATE

The instruction contains an 8-bit immediate field as the operand.

REGISTER INDIRECT (AUTO INCREMENT AND DECREMENT)

This is a register indirect mode that automatically increments or decrements the B or X register after executing the instruction.

RELATIVE

This mode is used for the JP instruction, the instruction field is added to the program counter to get the new program location. JP has a range of from -31 to +32 to allow a one byte relative jump (JP + 1 is implemented by a NOP instruction). There are no 'pages' when using JP, all 15 bits of PC are used.

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space.

Address	Contents
COP820C	
00 to 2F	On Chip RAM Bytes
30 to 7F	Unused RAM Address Space (Reads as all Ones)
COP840C	
00 to 6F	On Chip RAM Bytes
70 to 7F	Unused RAM Address Space (Reads as all Ones)
COP820C and COP840C	
80 to BF	Expansion Space for on Chip EERAM
C0 to CF	Expansion Space for I/O and Registers
D0 to DF	On Chip I/O and Registers
D0	Port L Data Register
D1	Port L Configuration Register
D2	Port L Input Pins (Read Only)
D3	Reserved for Port L
D4	Port G Data Register
D5	Port G Configuration Register
D6	Port G Input Pins (Read Only)
D7	Port I Input Pins (Read Only)
D8-DB	Reserved for Port C
DC	Port D Data Register
DD-DF	Reserved for Port D
E0 to EF	On Chip Functions and Registers
E0-E7	Reserved for Future Parts
E8	Reserved
E9	MICROWIRE/PLUS Shift Register
EA	Timer Lower Byte
EB	Timer Upper Byte
EC	Timer Autoload Register Lower Byte
ED	Timer Autoload Register Upper Byte
EE	CNTRL Control Register
EF	PSW Register
F0 to FF	On Chip RAM Mapped as Registers
FC	X Register
FD	SP Register
FE	B Register

Reading unused memory locations below 7FH will return all ones. Reading other unused memory locations will return undefined data.

Instruction Set

REGISTER AND SYMBOL DEFINITIONS

Registers

- A 8-bit Accumulator register
- B 8-bit Address register
- X 8-bit Address register
- SP 8-bit Stack pointer register
- PC 15-bit Program counter register
- PU upper 7 bits of PC
- PL lower 8 bits of PC
- C 1-bit of PSW register for carry
- HC Half Carry
- GIE 1-bit of PSW register for global interrupt enable

Symbols

- [B] Memory indirectly addressed by B register
- [X] Memory indirectly addressed by X register
- Mem Direct address memory or [B]
- Meml Direct address memory or [B] or Immediate data
- Imm 8-bit Immediate data
- Reg Register memory: addresses F0 to FF (Includes B, X and SP)
- Bit Bit number (0 to 7)
- ← Loaded with

where, i is the immediate data Md is a directly addressed memory location * is an unused opcode (see following table)

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instruction taking two bytes).

Most single instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

BYTES and CYCLES per INSTRUCTION

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

	[B]	Direct	Immed.

Option List

The COP820C/COP840C mask programmable options are listed out below. The options are programmed at the same time as the ROM pattern to provide the user with hardware flexibility to use a variety of oscillator configuration.

OPTION 1: CKI INPUT

- = 1 Crystal (CKI/10) CKO for crystal configuration
- = 2 External (CKI/10) CKO available as G7 input
- = 3 R/C (CKI/10) CKO available as G7 input

OPTION 2: COP820C/COP840C BONDING

- = 1 28 pin package
- = 2 N.A.
- = 3 20 pin package
- = 4 20 SO package
- = 5 28 SO package

The following option information is to be sent to National along with the EPROM.

Option Data

Option 1 Value__is: CKI Input

Option 2 Value__is: COP Bonding

How to Order

To order a complete development package, select the section for the microcontroller to be developed and order the parts listed.

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications Group. The Dial-A-Helper is an Electronic Bulletin Board information system.

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™—COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code

address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bargraph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefineable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information:

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink Base Unit In-circuit Emulator for all COP8 Devices, Symbolic Debugger Software and RS-232 Serial Interface Cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MHW-880C20D5PC	20 DIP	4.5V-5.5V	COP822C, 842C, 8782C
MHW-880C20DWPC	20 DIP	2.5V-6.0V	COP822C, 842C, 8782C
MHW-880C28D5PC	28 DIP	4.5V-5.5V	COP820C, 840C, 881C, 8781C
MHW-880C28DWPC	28 DIP	2.5V-6.0V	COP820C, 840C, 881C, 8781C

Development Support (Continued)

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 Macro Cross Assembler for IBM PC-XT®, PC-AT® or Compatible	424410527-001

SIMULATOR

The COP8 Designer's is Tool Kit is available for evaluating National Semiconductor's COP8 microcontroller family. The kit contains programmer's manuals, device datasheets, pocket reference guide, assembler and simulator, which allows the user to write, test, debug and run code on an industry standard compatible PC. The simulator has a windowed user interface and can handle script files that simulate hard-

ware inputs, interrupts and automatic command processing. The capture file feature enables the user to record to a file current cycle count and output port changes which are caused by the program under test.

Simulator Ordering Information

Part Number	Description	Manual
COP8-TOOL-KIT	COP8 Designer's Tool Kit Assembler and Simulator	420420270-001 424420269-001

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit, and function emulators. Two types of single chip emulators are available: Multi-Chip Module (MCM) emulators, which combine the microcontroller-die and an EPROM-die in one package, and emulators where the microcontroller's standard ROM is replaced with an on-chip EPROM. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

Single Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP881CMHD-X	X = 1: Crystal X = 2: External X = 3: R/C	28 DIP	Multi-Chip Module (MCM), UV Erasable	COP840C, COP820C
COP881CMHEA-X	X = 1: Crystal X = 2: External X = 3: R/C	28 LCC	MCM, (Same Footprint as 28 SO), UV Erasable	COP840C, COP820C

COP8782CWM	Programmable	20 SO	OTP	COP842C, COP822C
COP8782CMC	Programmable	20 SO	UV Erasable	COP842C, COP822C

Development Support (Continued)

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa.

Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 FAX: (206) 882-1043

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator Board for 28 DIP and for Use with Scrambler Boards	COP881CMHD
COP8-SCRM-DIP	Multi-Chip Module (MCM) Scrambler Board for 20 DIP Socket	COP842CMHD, COP822CMHD
COP8-SCRM-SBX	MCM Scrambler Board for 28 LCC Sockets	COP881CMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler Board	COP881CMHD, 842CMHD, 822CMHD
COP8-PRGM-87A	Duplicator Board with COP87XX Scrambler for 28 DIP and 28 SO	COP8781CN, 8781CJ, 8781CWM, 8781CMC

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down-loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:

Dial-A-Helper Users Manual

Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 baud

Setup: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs. 7 Days

COP820CJ/COP822CJ/COP823CJ

Single-Chip microCMOS Microcontroller

General Description

The COP820CJ is a member of the COPSM 8-bit Microcontroller family. It is a fully static Microcontroller, fabricated using double-metal silicon gate microCMOS technology. This low cost Microcontroller is a complete microcomputer containing all system timing, interrupt logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include an 8-bit memory mapped architecture, MICROWIRETM serial I/O, a 16-bit timer/counter with capture register, a multi-sourced interrupt, Comparator, WATCHDOGTM Timer, Modulator/Timer, Brown out protection and Multi-Input Wakeup. Each I/O pin has software selectable options to adapt the device to the specific application. The device operates over a voltage range of 2.5V to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a 1 μ s per instruction rate.

Features

- Low cost 8-bit Microcontroller
- Fully static CMOS
- 1 μ s instruction time
- Low current drain
 - Low current static HALT mode
- Single supply operation: 2.5V to 6.0V
- 1024 x 8 on-chip ROM
- 64 bytes on-chip RAM
- WATCHDOG Timer
- Comparator
- Modulator/Timer (High speed PWM Timer for IR Transmission)
- Multi-Input Wakeup (on the 8-bit Port L)
- Brown Out Protection
- 4 high current I/O pins with 15 mA sink capability
- MICROWIRE/PLUSTSM serial I/O
- 16-bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - External interrupt with selectable edge
 - Timer interrupt or capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set, most instructions single byte
- BCD arithmetic instructions
- 28- and 20-pin DIP/SO package or 16-pin SO package
- Software selectable I/O options (TRI-STATE[®], push-pull, weak pull-up)
- Schmitt trigger inputs on Port G and Port L
- Fully supported by National's development system
- Form Factor Emulator

Block Diagram

FIGURE 1. COP820CJ Block Diagram

TL/DD/11208-1

COP820CJ/COP822CJ/COP823CJ**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7.0V
Voltage at any Pin	-0.3V to $V_{CC} + 0.3V$
Total Current into V_{CC} pin (Source)	80 mA

Total Current out of GND pin (sink) 80 mA
Storage Temperature Range -65°C to +150°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur.

DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics -40°C ≤ T_A ≤ +85°C unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units
Operating Voltage	Brown Out Disabled	2.5		6.0	V
Power Supply Ripple 1 (Note 1)	Peak to Peak			0.1 V_{CC}	V
Supply Current (Note 2)					
CKI = 10 MHz	$V_{CC} = 6V, t_c = 1 \mu s$			8.0	mA
CKI = 4 MHz	$V_{CC} = 6V, t_c = 2.5 \mu s$			6.0	mA
CKI = 4 MHz	$V_{CC} = 4.0V, t_c = 2.5 \mu s$			2.5	mA
CKI = 1 MHz	$V_{CC} = 4.0V, t_c = 10 \mu s$			1.5	mA
HALT Current with Brown Out Disabled (Note 3)	$V_{CC} = 6V, CKI = 0 MHz$		<1	10	μA
HALT Current with Brown Out Enabled	$V_{CC} = 6V, CKI = 0 MHz$		<50	100	μA
Brown Out Trip Level (Brown Out Enabled)		1.8	3.1	4.2	V
INPUT LEVELS (V_{IH}, V_{IL})					
Reset, CKI:					
Logic High		0.8 V_{CC}			V
Logic Low				0.2 V_{CC}	V
All Other Inputs					
Logic High		0.7 V_{CC}			V
Logic Low				0.2 V_{CC}	V
Hi-Z Input Leakage	$V_{CC} = 6.0V$	-2		+2	μA
Input Pullup Current	$V_{CC} = 6.0V$	40		250	μA
L- and G-Port Hysteresis (Note 5)			0.05 V_{CC}	0.35 V_{CC}	V
Output Current Levels					
D Outputs:					
Source	$V_{CC} = 4.5V, V_{OH} = 3.8V$	0.4			mA
	$V_{CC} = 2.5V, V_{OH} = 1.8V$	0.2			mA
Sink	$V_{CC} = 4.5V, V_{OL} = 1.0V$	10			mA
	$V_{CC} = 2.5V, V_{OH} = 0.4V$	2			mA
L4-L7 Output Sink	$V_{CC} = 4.5V, V_{OL} = 2.5V$	15			mA
All Others					
Source (Weak Pull-up Mode)	$V_{CC} = 4.5V, V_{OH} = 3.2V$	10		110	μA
	$V_{CC} = 2.5V, V_{OH} = 1.8V$	2.5		33	μA
Source (Push-pull Mode)	$V_{CC} = 4.5V, V_{OH} = 3.8V$	0.4			mA
	$V_{CC} = 2.5V, V_{OH} = 1.8V$	0.2			mA
Sink (Push-pull Mode)	$V_{CC} = 4.5V, V_{OL} = 0.4V$	1.6			mA
	$V_{CC} = 2.5V, V_{OL} = 0.4V$	0.7			mA
TRI-STATE Leakage		-2.0		+2.0	μA
Allowable Sink/Source Current Per Pin					
D Outputs				15	mA
L4-L7 (Sink)				20	mA
All Others				3	mA

DC Electrical Characteristics $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ unless otherwise specified (Continued)

Parameter	Conditions	Min	Typ	Max	Units
Maximum Input Current without Latchup (Note 4)	Room Temperature			± 100	mA
RAM Retention Voltage, V_r	500 ns Rise and Fall Time (Min)	2.0			V
Input Capacitance				7	pF
Load Capacitance on D2				1000	pF

Note 1: Rate of voltage change must be less than 10 V/mS.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and crystal configurations. HALT test conditions: L, and G0..G5 ports configured as outputs and set high. The D port set to zero. All inputs tied to V_{CC} . The comparator and the Brown Out circuits are disabled.

Note 4: Pins G6 and RESET are designed with a high voltage input network. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

AC Electrical Characteristics $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units

Pin Description

V_{CC} and **GND** are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

RESET is the master reset input. See Reset description.

PORT I is a 4-bit Hi-Z input port.

PORT L is an 8-bit I/O port.

There are two registers associated with the L port: a data register and a configuration register. Therefore, each L

I/O bit can be individually configured under software control as shown below:

Port L Config.	Port L Data	Port L Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input with Weak Pull-up
1	0	Push-pull Zero Output
1	1	Push-pull One Output

Three data memory address locations are allocated for this port, one each for data register [00D0], configuration register [00D1] and the input pins [00D2].

Port L has the following alternate features:

L0 MIWU or CMPOUT

L1 MIWU or CMPIN-

L2 MIWU or CMPIN+

L3 MIWU

L4 MIWU (high sink current capability)

L5 MIWU (high sink current capability)

L6 MIWU (high sink current capability)

L7 MIWU or MODOUT (high sink current capability)

The selection of alternate Port L functions is done through registers WKEN [00C9] to enable MIWU and CNTRL2 [00CC] to enable comparator and modulator.

All eight L-pins have Schmitt Triggers on their inputs.

PORT G is an 8-bit port with 6 I/O pins (G0-G5) and 2 input pins (G6, G7).

All eight G-pins have Schmitt Triggers on the inputs.

There are two registers associated with the G port: a data register and a configuration register. Therefore each G port bit can be individually configured under software control as shown below:

Port G Config.	Port G Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input with Weak Pull-up
1	0	Push-pull Zero Output
1	1	Push-pull One Output

Three data memory address locations are allocated for this port, one for data register [00D3], one for configuration register [00D5] and one for the input pins [00D6]. Since G6 and G7 are Hi-Z input only pins, any attempt by the user to configure them as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. Note that the device will be placed in the Halt mode by writing a "1" to the G7 data bit.

Six pins of Port G have alternate features:

G0 INTR (an external interrupt)

G3 TIO (timer/counter input/output)

G4 SO (MICROWIRE serial data output)

G5 SK (MICROWIRE clock I/O)

G6 SI (MICROWIRE serial data input)

G7 CKO crystal oscillator output (selected by mask option) or HALT restart input/general purpose input (if clock option is R/C or external clock)

Pin Description (Continued)

Pins G1 and G2 currently do not have any alternate functions.

The selection of alternate Port G functions are done through registers PSW [00EF] to enable external interrupt and CNTRL1 [00EE] to select TIO and MICROWIRE operations.

PORT D is a four bit output port that is preset when RESET goes low. One data memory address location is allocated for the data register [00DC].

Note: Care must be exercised with the D2 pin operation. At RESET, the external loads on this pin must ensure that the output voltages stay above $0.8 V_{CC}$ to prevent the chip from entering special modes. Also keep the external loading on D2 to less than 1000 pF.

Functional Description

The internal architecture is shown in the block diagram. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device.

ALU and CPU Registers

The ALU can do an 8-bit addition, subtraction, logical or shift operations in one cycle time. There are five CPU registers:

- A is the 8-bit Accumulator register
- PC is the 15-bit Program Counter register
 - PU is the upper 7 bits of the program counter (PC)
 - PL is the lower 8 bits of the program counter (PC)
- B is the 8-bit address register and can be auto incremented or decremented.
- X is the 8-bit alternate address register and can be auto incremented or decremented.
- SP is the 8-bit stack pointer which points to the subroutine stack (in RAM).

B, X and SP registers are mapped into the on chip RAM. The B and X registers are used to address the on chip RAM. The SP register is used to address the stack in RAM during subroutine calls and returns. The SP must be preset by software upon initialization.

Memory

The COP820CJ memory is separated into two memory spaces: program and data.

PROGRAM MEMORY

Program memory consists of 1024 x 8 ROM. These bytes of ROM may be instructions or constant data. The memory is addressed by the 15-bit program counter (PC). ROM can be indirectly read by the LAID instruction for table lookup.

DATA MEMORY

The data memory address space includes on chip RAM, I/O and registers. Data memory is addressed directly by the instruction or indirectly through B, X and SP registers. The device has 64 bytes of RAM. Sixteen bytes of RAM are mapped as "registers", these can be loaded immediately, decremented and tested. Three specific registers: X, B, and SP are mapped into this space, the other registers are available for general usage.

Any bit of data memory can be directly set, reset or tested. All I/O and registers (except A and PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested, except the write once only bit (WDREN, WATCHDOG Reset Enable), and the unused and read only bits in CNTRL2 and WDREG registers.

Reset

EXTERNAL RESET

The RESET input pin when pulled low initializes the microcontroller. The user must insure that the RESET pin is held low until V_{CC} is within the specified voltage range and the clock is stabilized. An R/C circuit with a delay 5x greater than the power supply rise time is recommended (Figure 4). The device immediately goes into reset state when the RESET input goes low. When the RESET pin goes high the device comes out of reset state synchronously. The device will be running within two instruction cycles of the RESET pin going high. The following actions occur upon reset:

Port L	TRI-STATE
Port G	TRI-STATE
Port D	HIGH
PC	CLEARED
RAM Contents	RANDOM with Power-On-Reset UNAFFECTED with external Reset (power already applied)
B, X, SP	Same as RAM
PSW, CNTRL1, CNTRL2 and WDREG Reg.	CLEARED
Multi-Input Wakeup Reg. WKEDG, WKEN WKPND	CLEARED UNKNOWN
Data and Configuration Registers for L & G	CLEARED
WATCHDOG Timer	Prescaler/Counter each loaded with FF

The device comes out of the HALT mode when the RESET pin is pulled low. In this case, the user has to ensure that the RESET signal is low long enough to allow the oscillator to restart. An internal 256 t_c delay is normally used in conjunction with the two pin crystal oscillator. When the device comes out of the HALT mode through Multi-Input Wakeup, this delay allows the oscillator to stabilize.

The following additional actions occur after the device comes out of the HALT mode through the RESET pin.

If a two pin crystal/resonator oscillator is being used:

RAM Contents	UNCHANGED
Timer T1 and A Contents	UNKNOWN
WATCHDOG Timer Prescaler/Counter	ALTERED

If the external or RC Clock option is being used:

RAM Contents	UNCHANGED
Timer T1 and A Contents	UNCHANGED
WATCHDOG Timer Prescaler/Counter	ALTERED

The external RESET takes priority over the Brown Out Reset.

Functional Description (Continued)

Note: If the RESET pin is pulled low while Brown Out occurs (Brown Out circuit has detected Brown Out condition), the external reset will not occur until the Brown Out condition is removed. External reset has priority only if V_{CC} is greater than the Brown Out voltage.

$RC > 5 \times \text{Power Supply Rise Time}$

TL/DD/11208-6

FIGURE 4. Recommended Reset Circuit

WATCHDOG RESET

With WATCHDOG enabled, the WATCHDOG logic resets the device if the user program does not service the WATCHDOG timer within the selected service window. The WATCHDOG reset does not disable the WATCHDOG. Upon WATCHDOG reset, the WATCHDOG Prescaler/Counter are each initialized with FF Hex.

The following actions occur upon WATCHDOG reset that are different from external reset.

WDREN WATCHDOG Reset Enable bit UNCHANGED
WDUDF WATCHDOG Underflow bit UNCHANGED

Additional initialization actions that occur as a result of WATCHDOG reset are as follows:

Port L	TRI-STATE
Port G	TRI-STATE
Port D	HIGH
PC	CLEARED
Ram Contents	UNCHANGED
B, X, SP	UNCHANGED
PSW, CNTRL1 and CNTRL2 (except WDUDF Bit) Registers	CLEARED
Multi-Input Wakeup Registers WKEDG, WKEN WKPND	CLEARED UNKNOWN
Data and Configuration Registers for L & G	CLEARED
WATCHDOG Timer	Prescaler/Counter each loaded with FF

BROWN OUT RESET

The on-board Brown Out protection circuit resets the device when the operating voltage (V_{CC}) is lower than the Brown Out voltage. The device is held in reset when V_{CC} stays below the Brown Out Voltage. The device will remain in RESET as long as V_{CC} is below the Brown Out Voltage. The Device will resume execution if V_{CC} rises above the Brown Out Voltage. If a two pin crystal/resonator clock option is selected, the Brown Out reset will trigger a 256tc delay. This delay allows the oscillator to stabilize before the device exits the reset state. The delay is not used if the clock option is either R/C or external clock. The contents of data registers and RAM are unknown following a Brown Out reset. The external reset takes priority over Brown Out Reset and will deactivate the 256 tc cycles delay if in progress. The Brown Out reset takes priority over the WATCHDOG reset.

The following actions occur as a result of Brown Out reset:

Port L	TRI-STATE
Port G	TRI-STATE
Port D	HIGH
PC	CLEARED
RAM Contents	RANDOM
B, X, SP	UNKNOWN
PSW, CNTRL1, CNTRL2 and WDREG Registers	CLEARED
Multi-Input Wakeup Registers WKEDG, WKEN WKPND	CLEARED UNKNOWN
Data and Configuration Registers for L & G	CLEARED
WATCHDOG Timer	Prescaler/Counter each loaded with FF
Timer T1 and Accumulator	Unknown data after coming out of the HALT (through Brown Out Reset) with any Clock option

Note: The development system will detect the BROWN OUT RESET externally and will force the RESET pin low. The Development System does not emulate the 256tc delay.

Brown Out Protection

An on-board protection circuit monitors the operating voltage (V_{CC}) and compares it with the minimum operating voltage specified. The Brown Out circuit is designed to reset the device if the operating voltage is below the Brown Out voltage (between 1.8V to 4.2V at -40°C to $+85^{\circ}\text{C}$). The Minimum operating voltage for the device is 2.5V with Brown Out disabled, but with BROWN OUT enabled the device is guaranteed to operate properly down to minimum Brown Out voltage (Max frequency 4 MHz). For temperature range of 0°C to 70°C the Brown Out voltage is expected to be between 1.9V to 3.9V. The circuit can be enabled or disabled by Brown Out mask option. If the device is intended to operate at lower V_{CC} (lower than Brown Out voltage VBO max), the Brown Out circuit should be disabled by the mask option.

The Brown Out circuit may be used as a power-up reset provided the power supply rise time is slower than 50 μs (0V to 6.0V).

Note: Brown Out Circuit is active in HALT mode (with the Brown Out mask option selected).

Mask Options

The COP820CJ has the following mask options associated with it:

G7 can be used either as a general purpose input or a control input to continue from the HALT mode.

The CKI and the CKO pins are automatically configured by selecting one of the three options.

The device can be driven by a clock input which can be between DC and 10 MHz.

Functional Description (Continued)

#	Option	Value	Description	Comments
1	CKI Input	1	Crystal Oscillator	(Divide by 10)
		2	External Oscillator	(Divide by 10) CKO available as G7 input
		3	R/C Oscillator	(Divide by 10) CKO available as G7 Input

Oscillator Circuits

EXTERNAL OSCILLATOR

CKI can be driven by an external clock signal provided it meets the specified duty cycle, rise and fall times, and input levels. CKO is available as a general purpose input G7 and/or Halt control.

CRYSTAL OSCILLATOR

By selecting CKO as a clock output, CKI and CKO can be connected to create a crystal controlled oscillator. Table I shows the component values required for various standard crystal values.

R/C OSCILLATOR

By selecting CKI as a single pin oscillator, CKI can make a R/C oscillator. CKO is available as a general purpose input and/or HALT control. Table II shows variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/11208-7

FIGURE 5. Clock Oscillator Configurations

TABLE I. Crystal Oscillator Configuration

R1 (kΩ)	R2 (MΩ)	C1 (pF)	C2 (pF)	CKI Freq. (MHz)	Conditions
0	1	30	30-36	10	V _{CC} = 5V
0	1	30	30-36	4	V _{CC} = 5V
5.6	1	100	100-156	0.455	V _{CC} = 5V

5.6	100	1.1 to 1.3	7.4 to 9.0	V _{CC} = 5V
6.8	100	0.9 to 1.1	8.8 to 10.8	V _{CC} = 5V

2

Functional Description (Continued)

Current Drain

The total current drain of the chip depends on:

1. Oscillator operating mode - I1
2. Internal switching current - I2
3. Internal leakage current - I3
4. Output source current - I4
5. DC current caused by external input not at V_{CC} or GND - I5
6. DC current caused by the comparator (if comparator is enabled) - I6
7. DC current caused by the Brown Out - I7

Thus the total current drain is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5 + I_6 + I_7$$

To reduce the total current drain, each of the above components must be minimum. Operating with a crystal network will draw more current than an external square-wave. The R/C-mode will draw the most. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

The following formula may be used to compute total current drain when operating the controller in different modes.

$$I_2 = C \times V \times f$$

where: C = equivalent capacitance of the chip

V = operating voltage

f = CKI frequency

Halt Mode

The COP820CJ is a fully static device. The device enters the HALT mode by writing a one to the G7 bit of the G data register. Once in the HALT mode, the internal circuitry does not receive any clock signal and is therefore frozen in the exact state it was in when halted. In this mode the chip will only draw leakage current (output current and DC current due to the Brown Out circuit if Brown Out is enabled).

The device supports four different methods of exiting the HALT mode. The first method is with a low to high transition on the CKO (G7) pin. This method precludes the use of the crystal clock configuration (since CKO is a dedicated output). It may be used either with an RC clock configuration or an external clock configuration. The second method of exiting the HALT mode is with the multi-Input Wakeup feature on the L port. The third method of exiting the HALT mode is by pulling the RESET input low. The fourth method is with the operating voltage going below Brown Out voltage (if Brown Out is enabled by mask option).

If the two pin crystal/resonator oscillator is being used and Multi-Input Wakeup or Brown Out causes the device to exit the HALT mode, the WAKEUP signal does not allow the chip to start running immediately since crystal oscillators have a delayed start up time to reach full amplitude and frequency stability. The WATCHDOG timer (consisting of an 8-bit prescaler followed by an 8-bit counter) is used to generate a fixed delay of 256tc to ensure that the oscillator has indeed stabilized before allowing instruction execution. In this case, upon detecting a valid WAKEUP signal only the oscillator circuitry is enabled. The WATCHDOG Counter and Prescaler are each loaded with a value of FF Hex. The WATCHDOG prescaler is clocked with the tc instruction cycle. (The tc clock is derived by dividing the oscillator clock down by a factor of 10). The Schmitt trigger following the CKI inverter on the chip ensures that the WATCHDOG timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specs. This Schmitt trigger is not part of the oscillator closed loop. The start-up timeout from the WATCHDOG timer enables the clock signals to be routed to the rest of the chip. The delay is not activated when the device comes out of HALT mode through RESET pin. Also, if the clock option is either RC or External clock, the delay is not used, but the WATCHDOG Prescaler/-Counter contents are changed. The Development System will not emulate the 256tc delay.

The RESET pin or Brown Out will cause the device to reset and start executing from address X'0000. A low to high transition on the G7 pin (if single pin oscillator is used) or Multi-Input Wakeup will cause the device to start executing from the address following the HALT instruction.

When RESET pin is used to exit the device from the HALT mode and the two pin crystal/resonator (CKI/CKO) clock option is selected, the contents of the Accumulator and the Timer T1 are undetermined following the reset. All other information except the WATCHDOG Prescaler/Counter contents is retained until continuing. If the device comes out of the HALT mode through Brown Out reset, the contents of data registers and RAM are unknown following the reset. All information except the WATCHDOG Prescaler/Counter contents is retained if the device exits the HALT mode through G7 pin or Multi-Input Wakeup.

G7 is the HALT-restart pin, but it can still be used as an input. If the device is not halted, G7 can be used as a general purpose input.

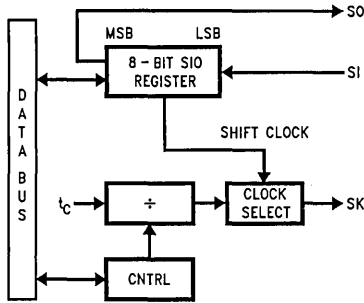

If the Brown Out Enable mask option is selected, the Brown Out circuit remains active during the HALT mode causing additional current to be drawn.

Note: To allow clock resynchronization, it is necessary to program two NOP's immediately after the device comes out of the HALT mode. The user must program two NOP's following the "enter HALT mode" (set G7 data bit) instruction.

Functional Description (Continued)

MICROWIRE/PLUS

MICROWIRE/PLUS is a serial synchronous bidirectional communications interface. The MICROWIRE/PLUS capability enables the device to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, EEPROMs, etc.) and with other microcontrollers which support the MICROWIRE/PLUS interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). *Figure 6* shows the block diagram of the MICROWIRE/PLUS interface.

TL/DD/11208-8

FIGURE 6. MICROWIRE/PLUS Block Diagram

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS interface with the internal clock source is called the Master mode of operation. Operating the MICROWIRE/PLUS interface with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. The SK clock rate is selected by the two bits, S0 and S1, in the CNTRL register. Table III details the different clock rates that may be selected.

TABLE III

S1	S0	SK Cycle Time
0	0	2t _c
0	1	4t _c
1	x	8t _c

where,
t_c is the instruction cycle time.

MICROWIRE/PLUS OPERATION

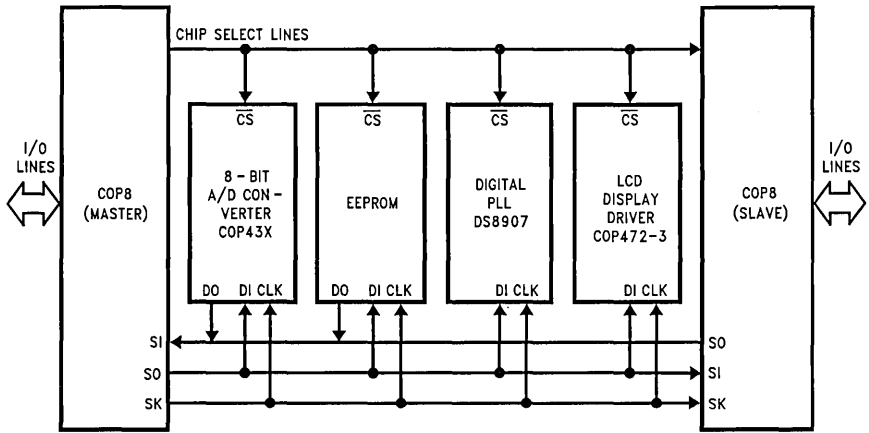

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS arrangement to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. The device may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. *Figure 7* shows how two device microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangement.

Master MICROWIRE/PLUS Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the device. The MICROWIRE/PLUS Master always initiates all data exchanges (*Figure 7*). The MSEL bit in the CNTRL register must be set to enable the SO and SK functions on the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table IV summarizes the bit settings required for Master mode of operation.

SLAVE MICROWIRE/PLUS OPERATION

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions on the G Port. The SK pin must be selected as an input and the SO pin selected as an output pin by appropriately setting up the Port G configuration register. Table IV summarizes the settings required to enter the Slave mode of operation.

TL/DD/11208-23

FIGURE 7. MICROWIRE/PLUS Application

Functional Description (Continued)

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated.

TABLE IV

G4 Config. Bit	G5 Config. Bit	G4 Fun.	G5 Fun.	G6 Fun.	Operation
1	1	SO	Int. SK	SI	MICROWIRE Master
0	1	TRI-STATE	Int. SK	SI	MICROWIRE Master
1	0	SO	Ext. SK	SI	MICROWIRE Slave
0	0	TRI-STATE	Ext. SK	SI	MICROWIRE Slave

TIMER/COUNTER

The device has a powerful 16-bit timer with an associated 16-bit register enabling it to perform extensive timer functions. The timer T1 and its register R1 are each organized as two 8-bit read/write registers. Control bits in the register CNTRL allow the timer to be started and stopped under software control. The timer-register pair can be operated in one of three possible modes. Table V details various timer operating modes and their requisite control settings.

MODE 1. TIMER WITH AUTO-LOAD REGISTER

In this mode of operation, the timer T1 counts down at the instruction cycle rate. Upon underflow the value in the regis-

ter R1 gets automatically reloaded into the timer which continues to count down. The timer underflow can be programmed to interrupt the microcontroller. A bit in the control register CNTRL enables the TIO (G3) pin to toggle upon timer underflows. This allows the generation of square-wave outputs or pulse width modulated outputs under software control (Figure 8).

MODE 2. EXTERNAL COUNTER

In this mode, the timer T1 becomes a 16-bit external event counter. The counter counts down upon an edge on the TIO pin. Control bits in the register CNTRL program the counter to decrement either on a positive edge or on a negative edge. Upon underflow the contents of the register R1 are automatically copied into the counter. The underflow can also be programmed to generate an interrupt (Figure 9).

FIGURE 8. Timer/Counter Auto Reload Mode Block Diagram

TL/DD/11208-24

TABLE V. Timer Operating Modes

CNTRL Bits 7 6 5	Operation Mode	T Interrupt	Timer Counts On
0 0 0	External Counter w/Auto-Load Reg.	Timer Underflow	TIO Pos. Edge
0 0 1	External Counter w/Auto-Load Reg.	Timer Underflow	TIO Neg. Edge
0 1 0	Not Allowed	Not Allowed	Not Allowed
0 1 1	Not Allowed	Not Allowed	Not Allowed
1 0 0	Timer w/Auto-Load Reg.	Timer Underflow	t_c
1 0 1	Timer w/Auto-Load Reg./Toggle TIO Out	Timer Underflow	t_c
1 1 0	Timer w/Capture Register	TIO Pos. Edge	t_c
1 1 1	Timer w/Capture Register	TIO Neg. Edge	t_c

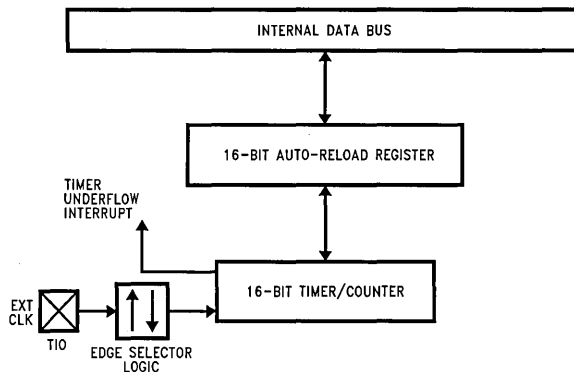

FIGURE 9. Timer in External Event Counter Mode

TL/DD/11208-29

Functional Description (Continued)

MODE 3: TIMER WITH CAPTURE REGISTER

Timer T1 can be used to precisely measure external frequencies or events in this mode of operation. The timer T1 counts down at the instruction cycle rate. Upon the occurrence of a specified edge on the TIO pin the contents of the timer T1 are copied into the register R1. Bits in the control register CNTRL allow the trigger edge to be specified either as a positive edge or as a negative edge. In this mode the user can elect to be interrupted on the specified trigger edge (Figure 10).

FIGURE 10. Timer Capture Mode Block Diagram

TIMER PWM APPLICATION

Figure 11 shows how a minimal component D/A converter can be built out of the Timer-Register pair in the Auto-Reload mode. The timer is placed in the "Timer with auto reload" mode and the TIO pin is selected as the timer output. At the outset the TIO pin is set high, the timer T1 holds the on time and the register R1 holds the signal off time. Setting TRUN bit starts the timer which counts down at the instruction cycle rate. The underflow toggles the TIO output and copies the off time into the timer, which continues to run. By alternately loading in the on time and the off time at each successive interrupt a PWM frequency can be easily generated.

FIGURE 11. Timer Application

WATCHDOG

The COP820CJ has an on-board 8-bit WATCHDOG timer. The timer contains an 8-bit READ/WRITE down counter clocked by an 8-bit prescaler. Under software control the timer can be dedicated for the WATCHDOG or used as a general purpose counter. Figure 12 shows the WATCHDOG timer block diagram.

MODE 1: WATCHDOG TIMER

The WATCHDOG is designed to detect user programs getting stuck in infinite loops resulting in loss of program control or "runaway" programs. The WATCHDOG can be enabled or disabled (only once) after the device is reset as a result of brown out reset or external reset. On power-up the WATCHDOG is disabled. The WATCHDOG is enabled by writing a "1" to WDREN bit (resides in WDREG register). Once enabled, the user program should write periodically into the 8-bit counter before the counter underflows. The 8-bit counter (WDCNT) is memory mapped at address 0CE Hex. The counter is loaded with n-1 to get n counts. The counter underflow resets the device, but does not disable the WATCHDOG. Loading the 8-bit counter initializes the prescaler with FF Hex and starts the prescaler/counter. Prescaler and counter are stopped upon counter underflow. Prescaler and counter are each loaded with FF Hex when the device goes into the HALT mode. The prescaler is used for crystal/resonator start-up when the device exits the HALT mode through Multi-Input Wakeup. In this case, the prescaler/counter contents are changed.

MODE 2: TIMER

In this mode, the prescaler/counter is used as a timer by keeping the WDREN (WATCHDOG reset enable) bit at 0. The counter underflow sets the WUDF (underflow) bit and the underflow does not reset the device. Loading the 8-bit counter (load n-1 for n counts) sets the WDTE bit (WATCHDOG Timer Enable) to "1", loads the prescaler with FF, and starts the timer. The counter underflow stops the timer. The WDTE bit serves as a start bit for the WATCHDOG timer. This bit is set when the 8-bit counter is loaded by the user program. The load could be as a result of WATCHDOG service (WATCHDOG timer dedicated for WATCHDOG function) or write to the counter (WATCHDOG timer used as a general purpose counter). The bit is cleared upon Brown Out reset, WATCHDOG reset or external reset. The bit is not memory mapped and is transparent to the user program.

TABLE VI. WATCHDOG Control/Status

Parameter	HALT Mode	WD Reset	EXT/BOR Reset (Note 1)	Counter Load
8-Bit Prescaler	FF	FF	FF	FF
8-Bit WD Counter	FF	FF	FF	User Value
WDREN Bit	Unchanged	Unchanged	0	No Effect
WUDF Bit	0	Unchanged	0	0
WDTE Signal	Unchanged	0	0	1

Note 1: BOR is Brown Out Reset.

Functional Description (Continued)

CONTROL/STATUS BITS

WDUDF: WATCHDOG Timer Underflow Bit

This bit resides in the CNTRL2 Register. The bit is set when the WATCHDOG timer underflows. The underflow resets the device if the WATCHDOG reset enable bit is set (WDREN = 1). Otherwise, WDUDF can be used as the timer underflow flag. The bit is cleared upon Brown-Out reset, external reset, load to the 8-bit counter, or going into the HALT mode. It is a read only bit.

WDREN: WD Reset Enable

WDREN bit resides in a separate register (bit 0 of WDREG). This bit enables the WATCHDOG timer to generate a reset. The bit is cleared upon Brown Out reset, or external reset. The bit under software control can be written to only once (once written to, the hardware does not allow the bit to be changed during program execution).

WDREN = 1 WATCHDOG reset is enabled.

WDREN = 0 WATCHDOG reset is disabled.

Table VI shows the impact of Brown Out Reset, WATCHDOG Reset, and External Reset on the Control/Status bits.

FIGURE 12. WATCHDOG Timer Block Diagram

TL/DD/11208-15

Modulator/Timer

The Modulator/Timer contains an 8-bit counter and an 8-bit autoreload register (MODRL address 0CF Hex). The Modulator/Timer has two modes of operation, selected by the control bit MC3. The Modulator/Timer Control bits MC1, MC2 and MC3 reside in CNTRL2 Register.

MODE 1: MODULATOR

The Modulator is used to generate high frequency pulses on the modulator output pin (L7). The L7 pin should be configured as an output. The number of pulses is determined by the 8-bit down counter. Under software control the modulator input clock can be either CKI or tC. The tC clock is derived by dividing down the oscillator clock by a factor of 10. Three control bits (MC1, MC2, and MC3) are used for the Modulator/Timer output control. When MC2 = 1 and MC3 = 1, CKI is used as the modulator input clock. When MC2 = 0, and MC3 = 1, tC is used as the modulator input clock. The user loads the counter with the desired number of counts (256 max) and sets MC1 to start the counter. The modulator autoreload register is loaded with n-1 to get n pulses. CKI or tC pulses are routed to the modulator output (L7) until the counter underflows (Figure 13). Upon underflow the hardware resets MC1 and stops the counter. The L7 pin goes low and stays low until the counter is restarted by the user program. The user program has the responsibility to timeout the low time. Unless the number of counts is changed, the user program does not have to load the counter each time the counter is started. The counter can simply be started by setting the MC1 bit. Setting MC1 by software will load the counter with the value of the autoreload register. The software can reset MC1 to stop the counter.

MODE 2: PWM TIMER

The counter can also be used as a PWM Timer. In this mode, an 8-bit register is used to serve as an autoreload register (MODRL).

a. 50% Duty Cycle:

When MC1 is 1 and MC2, MC3 are 0, a 50% duty cycle free running signal is generated on the L7 output pin (Figure 14). The L7 pin must be configured as an output pin. In this mode the 8-bit counter is clocked by tC. Setting the MC1

control bit by software loads the counter with the value of the autoreload register and starts the counter. The counter underflow toggles the (L7) output pin. The 50% duty cycle signal will be continuously generated until MC1 is reset by the user program.

b. Variable Duty Cycle:

When MC3 = 0 and MC2 = 1, a variable duty cycle PWM signal is generated on the L7 output pin. The counter is clocked by tC. In this mode the 16-bit timer T1 along with the 8-bit down counter are used to generate a variable duty cycle PWM signal. The timer T1 underflow sets MC1 which starts the down counter and it also sets L7 high (L7 should be configured as an output). When the counter underflows the MC1 control bit is reset and the L7 output will go low until the next timer T1 underflow. Therefore, the width of the output pulse is controlled by the 8-bit counter and the pulse duration is controlled by the 16-bit timer T1 (Figure 15). Timer T1 must be configured in "PWM Mode/Toggle TIO Out" (CNTRL1 Bits 7,6,5 = 101).

Table VII shows the different operation modes for the Modulator/Timer.

TABLE VII. Modulator/Timer Modes

Control Bits in CNTRL2(00CC)			Operation Mode L7 Function
MC3	MC2	MC1	
0	0	0	Normal I/O
0	0	1	50% Duty Cycle Mode (Clocked by tc)
0	1	X	Variable Duty Cycle Mode (Clocked by tc) Using Timer 1 Underflow
1	0	X	Modulator Mode (Clocked by tc)
1	1	X	Modulator Mode (Clocked by CKI)

Note: MC1, MC2 and MC3 control bits are cleared upon reset.

Comparator

The COP820CJ has one differential comparator. Ports L0–L2 are used for the comparator. The output of the comparator is brought out to a pin. Port L has the following assignments:

- L0 Comparator output
- L1 Comparator negative input
- L2 Comparator positive input

THE COMPARATOR STATUS/CONTROL BITS

These bits reside in the CNTRL2 Register (Address 0CC)

- CMPEN Enables comparator ("1" = enable)
- CMPRD Reads comparator output internally (CMPEN = 1, CMPOE = X)
- CMPOE Enables comparator output to pin L0 ("1" = enable), CMPEN bit must be set to enable this function. If CMPEN = 0, L0 will be 0.

The Comparator Select/Control bits are cleared on RESET (the comparator is disabled). To save power the program should also disable the comparator before the device enters the HALT mode.

The user program must set up L0, L1 and L2 ports correctly for comparator Inputs/Output: L1 and L2 need to be configured as inputs and L0 as output. Table VIII shows the DC and AC characteristics for the comparator.

Multi-Input Wake Up

The Multi-Input Wakeup feature is used to return (wakeup) the device from the HALT mode. *Figure 16* shows the Multi-Input Wakeup logic.

This feature utilizes the L Port. The user selects which particular L port bit or combination of L Port bits will cause the device to exit the HALT mode. Three 8-bit memory mapped registers, Reg:WKEN, Reg:WKEDG, and Reg:WKPND are used in conjunction with the L port to implement the Multi-Input Wakeup feature.

All three registers Reg:WKEN, Reg:WKPND, and Reg:WKEDG are read/write registers, and are cleared at reset, except WKPND. WKPND is unknown on reset.

The user can select whether the trigger condition on the selected L Port pin is going to be either a positive edge (low to high transition) or a negative edge (high to low transition). This selection is made via the Reg:WKEDG, which is an 8-bit control register with a bit assigned to each L Port pin. Setting the control bit will select the trigger condition to be a negative edge on that particular L Port pin. Resetting the bit selects the trigger condition to be a positive edge. Changing an edge select entails several steps in order to avoid a pseudo Wakeup condition as a result of the edge change. First, the associated WKEN bit should be reset, followed by

the edge select change in WKEDG. Next, the associated WKPND bit should be cleared, followed by the associated WKEN bit being re-enabled.

An example may serve to clarify this procedure. Suppose we wish to change the edge select from positive (low going high) to negative (high going low) for L port bit 5, where bit 5 has previously been enabled for an input. The program would be as follows:

```

RBIT 5,WKEN
SBIT 5,WKEDG
RBIT 5,WKPND
SBIT 5,WKEN
  
```

If the L port bits have been used as outputs and then changed to inputs with Multi-Input Wakeup, a safety procedure should also be followed to avoid inherited pseudo wakeup conditions. After the selected L port bits have been changed from output to input but before the associated WKEN bits are enabled, the associated edge select bits in WKEDG should be set or reset for the desired edge selects, followed by the associated WKPND bits being cleared. This same procedure should be used following RESET, since the L port inputs are left floating as a result of RESET.

The occurrence of the selected trigger condition for Multi-Input Wakeup is latched into a pending register called Reg:WKPND. The respective bits of the WKPND register will be set on the occurrence of the selected trigger edge on the corresponding Port L pin. The user has the responsibility of clearing these pending flags. Since the Reg:WKPND is a pending register for the occurrence of selected wakeup conditions, the device will not enter the HALT mode if any Wakeup bit is both enabled and pending. Setting the G7 data bit under this condition will not allow the device to enter the HALT mode. Consequently, the user has the responsibility of clearing the pending flags before attempting to enter the HALT mode.

If a crystal oscillator is being used, the Wakeup signal will not start the chip running immediately since crystal oscillators have a finite start up time. The WATCHDOG timer prescaler generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the device to execute instructions. In this case, upon detecting a valid Wakeup signal only the oscillator circuitry and the WATCHDOG timer are enabled. The WATCHDOG timer prescaler is loaded with a value of FF Hex (256 counts) and is clocked from the tc instruction cycle clock. The tc clock is derived by dividing down the oscillator clock by a factor of 10. A Schmitt trigger following the CKI on chip inverter ensures that the WATCHDOG timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specs. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the WATCHDOG timer enables the clock signals to be routed to the rest of the chip.

TABLE VIII. DC and AC Characteristics $4V \leq V_{CC} \leq 6V$, $-40^{\circ}C \leq T_A \leq +85^{\circ}C$ (Note 1)

Parameters	Conditions	Min	Type	Max	Units
Input Offset Voltage	$0.4V < V_{IN} < V_{CC} - 1.5V$		± 10	± 25	mV

DC Supply Current (when enabled)	$V_{CC} = 6.0V$			250	μA
Response Time	TBD mV Step, TBD mV Overdrive, 100 pF Load			1	μs

Note 1: For comparator output current characteristics see L-Port specs.

Multi-Input Wakeup (Continued)

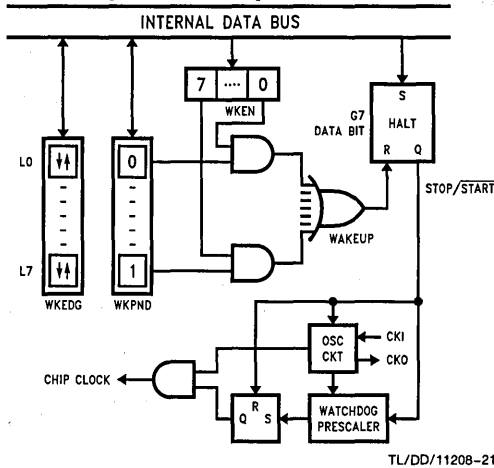

FIGURE 16. Multi-Input Wakeup Logic

INTERRUPTS

The device has a sophisticated interrupt structure to allow easy interface to the real world. There are three possible interrupt sources, as shown below.

A maskable interrupt on external G0 input (positive or negative edge sensitive under software control)

A maskable interrupt on timer carry or timer capture

A non-maskable software/error interrupt on opcode zero

INTERRUPT CONTROL

The GIE (global interrupt enable) bit enables the interrupt function. This is used in conjunction with ENI and ENTI to select one or both of the interrupt sources. This bit is reset when interrupt is acknowledged.

ENI and ENTI bits select external and timer interrupts respectively. Thus the user can select either or both sources to interrupt the microcontroller when GIE is enabled.

IEDG selects the external interrupt edge (0 = rising edge, 1 = falling edge). The user can get an interrupt on both rising and falling edges by toggling the state of IEDG bit after each interrupt.

IPND and TPND bits signal which interrupt is pending. After an interrupt is acknowledged, the user can check these two bits to determine which interrupt is pending. This permits the interrupts to be prioritized under software. The pending flags have to be cleared by the user. Setting the GIE bit high inside the interrupt subroutine allows nested interrupts.

The software interrupt does not reset the GIE bit. This means that the controller can be interrupted by other interrupt sources while servicing the software interrupt.

INTERRUPT PROCESSING

The interrupt, once acknowledged, pushes the program counter (PC) onto the stack and the stack pointer (SP) is decremented twice. The Global Interrupt Enable (GIE) bit is reset to disable further interrupts. The microcontroller then vectors to the address 00FFH and resumes execution from that address. This process takes 7 cycles to complete. At the end of the interrupt subroutine, any of the following three instructions return the processor back to the main program: RET, RETSK or RETI. Either one of the three instructions will pop the stack into the program counter (PC). The stack pointer is then incremented twice. The RETI instruction additionally sets the GIE bit to re-enable further interrupts.

Any of the three instructions can be used to return from a hardware interrupt subroutine. The RETSK instruction should be used when returning from a software interrupt subroutine to avoid entering an infinite loop.

DETECTION OF ILLEGAL CONDITIONS

The device incorporates a hardware mechanism that allows it to detect illegal conditions which may occur from coding errors, noise, and "brown out" voltage drop situations. Specifically, it detects cases of executing out of undefined ROM area and unbalanced tack situations.

Reading an undefined ROM location returns 00 (hexadecimal) as its contents. The opcode for a software interrupt is also "00". Thus a program accessing undefined ROM will cause a software interrupt.

Reading an undefined RAM location returns an FF (hexadecimal). The subroutine stack on the device grows down for each subroutine call. By initializing the stack pointer to the top of RAM, the first unbalanced return instruction will cause the stack pointer to address undefined RAM. As a result the program will attempt to execute from FFFF (hexadecimal), which is an undefined ROM location and will trigger a software interrupt.

FIGURE 17. Interrupt Block Diagram

Control Registers

CNTRL1 REGISTER (ADDRESS 00EE)

The Timer and MICROWIRE control register contains the following bits:

- SL1 and SL0 Select the MICROWIRE clock divide-by (00 = 2, 01 = 4, 1x = 8)
- IEDG External interrupt edge polarity select
- MSEL Selects G5 and G4 as MICROWIRE signals SK and SO respectively
- TRUN Used to start and stop the timer/counter (1 = run, 0 = stop)
- TC1 Timer T1 Mode Control Bit
- TC2 Timer T1 Mode Control Bit
- TC3 Timer T1 Mode Control Bit

Bit 7							Bit 0	
TC1	TC2	TC3	TRUN	MSEL	IEDG	SL1	SL0	

PSW REGISTER (ADDRESS 00EF)

The PSW register contains the following select bits:

- GIE Global interrupt enable (enables interrupts)
- ENI External interrupt enable
- BUSY MICROWIRE busy shifting flag
- PND External interrupt pending
- ENTI Timer T1 interrupt enable
- TPND Timer T1 interrupt pending (timer Underflow or capture edge)
- C Carry Flip/Flop
- HC Half-Carry Flip/Flop

Bit 7							Bit 0	
HC	C	TPND	ENTI	IPND	BUSY	ENI	GIE	

The Half-Carry bit is also effected by all the instructions that effect the Carry flag. The flag values depend upon the instruction. For example, after executing the ADC instruction the values of the Carry and the Half-Carry flag depend upon the operands involved. However, instructions like SET C and RESET C will set and clear both the carry flags. Table IX lists the instructions that effect the HC and the C flags.

TABLE IX. Instructions Effecting HC and C Flags

Instr.	HC Flag	C Flag
ADC	Depends on Operands	Depends on Operands
SUBC	Depends on Operands	Depends on Operands
SET C	Set	Set
RESET C	Set	Set
RRC	Depends on Operands	Depends on Operands

CNTRL2 REGISTER (ADDRESS 00CC)

Bit 7							Bit 0	
MC3	MC2	MC1	CMPEN	CMPRD	CMPOE	WDUDF	unused	
R/W	R/W	R/W	R/W	R/O	R/W	R/O		

- MC3 Modulator/Timer Control Bit
- MC2 Modulator/Timer Control Bit
- MC1 Modulator/Timer Control Bit
- CMPEN Comparator Enable Bit
- CMPRD Comparator Read Bit
- CMPOE Comparator Output Enable Bit
- WDUDF WATCHDOG Timer Underflow Bit (Read Only)

WDREG REGISTER (ADDRESS 00CD)

WDREN WATCHDOG Reset Enable Bit (Write Once Only)

Bit 7		Bit 0	
UNUSED		WDREN	

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space.

TABLE X. Memory Map

Address	Contents
00 to 2F	On-chip RAM bytes (48 bytes)
30 to 7F	Unused RAM Address Space (Reads as All Ones)
80 to BF	Expansion Space for On-Chip EERAM (Reads Undefined Data)
C0 to C7	Reserved
C8	MIWU Edge Select Register (Reg:WKEDG)
C9	MIWU Enable Register (Reg:WKEN)
CA	MIWU Pending Register (Reg:WKPND)
CB	Reserved
CC	Control2 Register (CNTRL2)
CD	WATCHDOG Register (WDREG)
CE	WATCHDOG Counter (WDCNT)
CF	Modulator Reload (MODRL)
D0	Port L Data Register
D1	Port L Configuration Register
D2	Port L Input Pins (Read Only)
D3	Reserved for Port L
D4	Port G Data Register
D5	Port G Configuration Register
D6	Port G Input Pins (Read Only)
D7	Port I Input Pins (Read Only)
D8 to DB	Reserved for Port C
DC	Port D Data Register
DD to DF	Reserved for Port D
E0 to EF	On-Chip Functions and Registers
E0 to E7	Reserved for Future Parts
E8	Reserved
E9	MICROWIRE Shift Register
EA	Timer Lower Byte
EB	Timer Upper Byte
EC	Timer1 Autoreload Register Lower Byte
ED	Timer1 Autoreload Register Upper Byte
EE	CNTRL1 Control Register
EF	PSW Register
F0 to FF	On-Chip RAM Mapped as Registers
FC	X Register
FD	SP Register
FE	B Register

Reading other unused memory locations will return undefined data.

Addressing Modes

The COP820CJ has ten addressing modes, six for operand addressing and four for transfer of control.

OPERAND ADDRESSING MODES

REGISTER INDIRECT

This is the "normal" addressing mode for the chip. The operand is the data memory addressed by the **B** or **X** pointer. REGISTER INDIRECT WITH AUTO POST INCREMENT OR DECREMENT

This addressing mode is used with the LD and X instructions. The operand is the data memory addressed by the **B** or **X** pointer. This is a register indirect mode that automatically post increments or post decrements the **B** or **X** pointer after executing the instruction.

DIRECT

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

IMMEDIATE

The instruction contains an 8-bit immediate field as the operand.

SHORT IMMEDIATE

This addressing mode issued with the LD B,# instruction, where the immediate # is less than 16. The instruction contains a 4-bit immediate field as the operand.

INDIRECT

This addressing mode is used with the LAID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a data operand from the program memory.

TRANSFER OF CONTROL ADDRESSING MODES

RELATIVE

This mode is used for the JP instruction with the instruction field being added to the program counter to produce the next instruction address. JP has a range from -31 to +32 to allow a one byte relative jump (JP + 1 is implemented by a NOP instruction). There are no "blocks" or "pages" when using JP since all 15 bits of the PC are used.

ABSOLUTE

This mode is used with the JMP and JSR instructions with the instruction field of 12 bits replacing the lower 12 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory segment.

ABSOLUTE LONG

This mode is used with the JMPL and JSRL instructions with the instruction field of 15 bits replacing the entire 15 bits of the program counter (PC). This allows jumping to any location in the entire 32k program memory space.

INDIRECT

This mode is used with the JID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a location in the program memory. The contents of this program memory location serves as a partial address (lower 8 bits of PC) for the jump to the next instruction.

Instruction Set

REGISTER AND SYMBOL DEFINITIONS

Registers

A	8-bit Accumulator register
B	8-bit Address register
X	8-bit Address register
SP	8-bit Stack pointer register
PC	15-bit Program counter register
PU	upper 7 bits of PC
PL	lower 8 bits of PC
C	1-bit of PSW register for carry
HC	Half Carry
GIE	1-bit of PSW register for global interrupt enable

Symbols

[B]	Memory indirectly addressed by B register
[X]	Memory indirectly addressed by X register
Mem	Direct address memory or [B]
Meml	Direct address memory or [B] or Immediate data
Imm	8-bit Immediate data
Reg	Register memory: addresses F0 to FF (Includes B, X and SP)
Bit	Bit number (0 to 7)
←	Loaded with
↔	Exchanged with

Instruction Set

ADD ADC	add add with carry	A ← A + Meml A ← A + Meml + C, C ← Carry HC ← Half Carry

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instruction taking two bytes).

Most single instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

BYTES and CYCLES per INSTRUCTION

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

Arithmetic Instructions (Bytes/Cycles)

	[B]	Direct	Immed.

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bargraph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS 232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MH-820CJ20D5PC	20 DIP	4.5V-5.5V	COP822CJ
MHW-820CJ20DWPC	20 DIP	2.3V-6.0V	COP822CJ
MHW-820CJ28D5PC	28 DIP	4.5V-5.5V	COP820CJ
MHW-820CJ28DWPC	28 DIP	2.3V-6.0V	COP820CJ

Development Support (Continued)

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM® PC-XT®, PC-AT® or compatible	424410527-001

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

SINGLE CHIP EMULATOR

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

Single Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP820CJMHD-X	X = 1: crystal X = 2: external X = 3: R/C	28 DIP	Multi-Chip Module (MCM), UV erasable	COP820CJ
COP820CJMHEA-X	X = 1: crystal X = 2: external X = 3: R/C	28 LCC	MCM (same footprint as 28 SO), UV erasable	COP820CJ
COP822CJMHD-X	X = 1: crystal X = 2: external X = 3: R/C	20 DIP	MCM, UV erasable	COP822CJ

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator board for 28 DIP and for use with Scrambler Boards	COP820CJMHD
COP8-SCRM-DIP	Scrambler board for 20 DIP socket	COP822CJMHD
COP8-SCRM-SBX	Scrambler board for 28 LCC sockets	COP820CJMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler board	COP822CJMHD COP820CJMHD
COP8-PRGM-SBX	Duplicator Board with COP8-SCRM-SBX Scrambler Board	COP820CJMHEA COP820CJHHD

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications Group. The Dial-A-Helper is an Electronic Bulletin Board information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down-loaded to disk for later use.

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user has questions, he can leave messages on our electronic bulletin board.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 baud

Setup: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs. 7 Days

COP8620C/COP8622C/COP8640C/COP8642C/ COP86L20C/COP86L22C/COP86L40C/COP86L42C Single-Chip microCMOS Microcontrollers

General Description

The COP8620C/COP8640C are members of the COP86™ microcontroller family. They are fully static parts, fabricated using double-metal silicon gate microCMOS technology. These low cost microcontrollers are complete microcomputers containing all system timing, interrupt logic, ROM, RAM, EEPROM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUSTM™ serial I/O, a 16-bit timer/counter with capture register and a multi-sourced interrupt. Each I/O pin has software selectable options to adapt the COP8620C/COP8640C to the specific application. The part operates over a voltage range of 4.5V to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a 1 microsecond per instruction rate.

Features

- Low Cost 8-bit microcontroller
- Fully static CMOS
- 1 μ s instruction time
- Low current drain (2.2 mA at 3 μ s instruction rate)
 Low current static HALT mode (Typically < 1 μ A)
- Single supply operation: 4.5 to 6.0V
- 2048 Bytes ROM/64 Bytes RAM/64 Bytes EEPROM on COP8640C

- 1024 bytes ROM/64 bytes RAM/64 bytes EEPROM on COP8620C
- 16-bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - Reset master clear
 - External interrupt with selectable edge
 - Timer interrupt or capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set, most instructions single byte
- BCD arithmetic instructions
- MICROWIRE PLUSTM™ serial I/O
- 28 pin package (optional 20 pin package)
- 24 input/output pins (28-pin package)
- Software selectable I/O options (TRI-STATE®, push-pull, weak pull-up)
- Schmitt trigger inputs on Port G
- Temperature range: -40°C to +85°C, -55°C to +125°C
- Compatible with COP8640CMH Series of Emulators
- Fully supported by National's Development Systems

Block Diagram

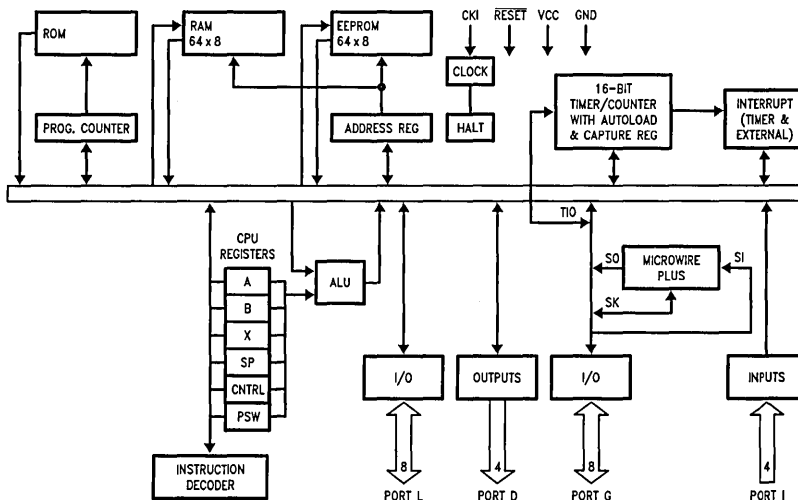

FIGURE 1

TL/DD/10366-1

COP86L20C/COP86L22C/COP86L40C/COP86L42C**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC}) 7V
 Voltage at any Pin $-0.3V$ to $V_{CC} + 0.3V$
 Total Current into V_{CC} Pin (Source) 50 mA

Total Current out of GND Pin (Sink) 60 mA
 Storage Temperature Range $-65^{\circ}C$ to $+140^{\circ}C$

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics $-40^{\circ}C \leq T_A \leq +85^{\circ}C$ unless otherwise specified

Parameter	Condition	Min	Typ	Max	Units
Operating Voltage		2.5		6.0	V
Power Supply Ripple (Note 1)	Peak to Peak			$0.1 V_{CC}$	V
Operating Voltage during EEPROM Write		4.5		6.0	V
Supply Current (Note 2) CKI = 10 MHz	$V_{CC} = 6V, t_c = 1 \mu s$			9	mA
Supply Current during Write Operation (Note 2) CKI = 10 MHz	$V_{CC} = 6.0V, t_c = 1 \mu s$			15	mA
HALT Current (Note 3)	$V_{CC} = 6V, CKI = 0 MHz$		<1	10	μA
Input Levels					
RESET, CKI					
Logic High		$0.9 V_{CC}$		$0.1 V_{CC}$	V
Logic Low					V
All Other Inputs					
Logic High		$0.7 V_{CC}$			V
Logic Low				$0.2 V_{CC}$	V
Hi-Z Input Leakage	$V_{CC} = 6.0V$	-2		+2	μA
Input Pullup Current	$V_{CC} = 6.0V, V_{IN} = 0V$	40		250	μA
G Port Input Hysteresis (Note 5)				$0.35 V_{CC}$	V
Output Current Levels					
D Outputs					
Source	$V_{CC} = 4.5V, V_{OH} = 3.8V$	0.4			mA
	$V_{CC} = 2.5V, V_{OH} = 1.8V$	0.2			mA
Sink	$V_{CC} = 4.5V, V_{OL} = 1.0V$	10			mA
	$V_{CC} = 2.5V, V_{OL} = 0.4V$	2			mA
All Others					
Source (Weak Pull-Up)	$V_{CC} = 4.5V, V_{OH} = 3.2V$	10		110	μA
	$V_{CC} = 2.5V, V_{OH} = 1.8V$	2.5		33	μA
Source (Push-Pull Mode)	$V_{CC} = 4.5V, V_{OH} = 3.8V$	0.4			mA
	$V_{CC} = 2.5V, V_{OH} = 1.8V$	0.2			mA
Sink (Push-Pull Mode)	$V_{CC} = 4.5V, V_{OL} = 0.4V$	1.6			mA
	$V_{CC} = 2.5V, V_{OL} = 0.4V$	0.7			mA
TRI-STATE Leakage		-2.0		+2.0	μA
Allowable Sink/Source Current Per Pin					
D Outputs (Sink)				15	mA
All Others				3	mA
Maximum Input Current (Note 4) Without Latchup (Room Temp) (Note 5)	Room Temp			± 100	mA
RAM Retention Voltage, V_r	500 ns Rise and Fall Time (Min)	2.0			V
Input Capacitance (Note 5)				7	pF
EEPROM Characteristics					
EEPROM Write Cycle Time				10	ms
EEPROM Number of Write Cycles				10,000	Cycle
EEPROM Data Retention		10			Years

Note 1: Rate of voltage change must be less than 0.5V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L and G ports are at TRI-STATE and tied to ground, all outputs low and tied to ground.

Note 4: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at G6 and RESET pins must be limited to less than 14V.

FIGURE 3

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

$\overline{\text{RESET}}$ is the master reset input. See Reset description.

PORT I is a four bit Hi-Z input port.

PORT L is an 8-bit I/O port.

There are two registers associated with each L I/O port: a data register and a configuration register. Therefore, each L I/O bit can be individually configured under software control as shown below:

Port L Config.	Port L Data	Port L Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input With Weak Pull-Up
1	0	Push-Pull "0" Output
1	1	Push-Pull "1" Output

Three data memory address locations are allocated for these ports, one for data register, one for configuration register and one for the input pins.

PORT G is an 8-bit port with 6 I/O pins (G0-G5) and 2 input pins (G6, G7). All eight G-pins have Schmitt Triggers on the inputs. The G7 pin functions as an input pin under normal operation and as the continue pin to exit the HALT mode. There are two registers with each I/O port: a data register and a configuration register. Therefore, each I/O bit can be individually configured under software control as shown below.

Port G Config.	Port G Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input With Weak Pull-Up
1	0	Push-Pull "0" Output
1	1	Push-Pull "1" Output

Three data memory address locations are allocated for these ports, one for data register, one for configuration register and one for the input pins. Since G6 and G7 are input only pins, any attempt by the user to set them up as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. Note that the chip will be placed in the HALT mode by setting the G7 data bit.

Six bits of Port G have alternate features:

G0 INTR (an external interrupt)

G3 TIO (timer/counter input/output)

G4 SO (MICROWIRE serial data output)

G5 SK (MICROWIRE clock I/O)

G6 SI (MICROWIRE serial data input)

G7 CKO crystal oscillator output (selected by mask option) or HALT restart input (general purpose input)

Pins G1 and G2 currently do not have any alternate functions.

PORT D is a four bit output port that is set high when $\overline{\text{RESET}}$ goes low.

Functional Description

Figure 1 shows the block diagram of the internal architecture. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device.

ALU AND CPU REGISTERS

The ALU can do an 8-bit addition, subtraction, logical or shift operation in one cycle time.

There are five CPU registers:

A is the 8-bit Accumulator register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is the 8-bit address register, can be auto incremented or decremented.

X is the 8-bit alternate address register, can be incremented or decremented.

SP is the 8-bit stack pointer, points to subroutine stack (in RAM).

B, X and SP registers are mapped into the on chip RAM. The B and X registers are used to address the on chip RAM. The SP register is used to address the stack in RAM during subroutine calls and returns.

PROGRAM MEMORY

Program memory for the COP8620C consists of 1024 bytes of ROM and the COP8640C consists of 2048 bytes of ROM. These bytes may hold program instructions or constant data. The program memory is addressed by the 15-bit program counter (PC). ROM can be indirectly read by the LAID instruction for table lookup.

DATA MEMORY

The data memory address space includes on chip RAM, EEPROM, I/O and registers. Data memory is addressed directly by the instruction or indirectly through B, X and SP registers.

The COP8620C/COP8640C has 64 bytes of RAM. Sixteen bytes of RAM are mapped as "registers", these can be loaded immediately and decremented and tested. Three specific registers: X, B, and SP are mapped into this space, the other registers are available for general usage.

Any bit of data memory can be directly set, reset or tested. I/O and registers (except A and PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested.

The COP8620C/COP8640C provides 64 bytes of EEPROM for nonvolatile data memory. The data EEPROM can be read and written in exactly the same way as the RAM. All instructions that perform read and write operations on the RAM work similarly upon the data EEPROM. The data EEPROM contains all 00s when shipped by the factory.

A data EEPROM programming cycle is initiated by an instruction such as X, LD, SBIT and RBIT. The EE memory support circuitry sets the BsyERAM flag in the EEER register immediately upon beginning a data EEPROM write cycle. It will be automatically reset by the hardware at the end of the data EEPROM write cycle. The application program should test the BsyERAM flag before attempting a write operation to the data EEPROM. A second EEPROM write operation while a write operation is in progress will be ignored and the Werr flag in the EEER register will be set to indicate the error status. Once the write operation starts, nothing will stop the write operation, not by resetting the device, and not even turning off the V_{CC} will guarantee the write operation to stop.

Functional Description (Continued)

EECR AND EE SUPPORT CIRCUITRY

The EEPROM module contains EE support circuits to generate all necessary high voltage programming pulses. An EEPROM cell in the erase state is read out as a 0 and the written state as a 1. The EECR register provides control, status and test mode functions for the EE module. The EECR register bit assignments are shown below.

Werr Write Error. Writing to EEPROM while a previous write cycle is still busy, that is BsyERAM is 1, causes Werr to be set to 1 indicating error status. Werr is a Read/Write bit and is cleared by writing a 0 into it.

BsyERAM This bit is a read only bit and is set to 1 when EEPROM is being written. It is automatically reset by the hardware upon completion of the write operation. This bit is not cleared by reset. If the bit is set upon power up or reset, the application program should test the BsyERAM flag and wait for the flag to go low before attempting a write operation to the data EEPROM.

Bits 4 to 7 of the EECR register are used for encoding various EEPROM module test modes, most of which are for factory manufacturing tests. Except BsyERAM (bit 3) the EECR is cleared by reset. EECR is mapped into address location E0. Bit 2 can be used as flag. Bits 1 and 4 are always read as "0" and cannot be used as flags.

RESET

The $\overline{\text{RESET}}$ input when pulled low initializes the microcontroller. Initialization will occur whenever the $\overline{\text{RESET}}$ input is pulled low. Upon initialization, the ports L and G are placed in the TRI-STATE mode and the Port D is set high. The PC, PSW and CNTRL registers are cleared. The data and configuration registers for Ports L & G are cleared. Except bit 3, the EECR register is cleared.

The external RC network shown in Figure 4 should be used to ensure that the $\overline{\text{RESET}}$ pin is held low until the power supply to the chip stabilizes.

OSCILLATOR CIRCUITS

Figure 5 shows the three clock oscillator configurations available for the COP8640C.

A. CRYSTAL OSCILLATOR

The COP8620C/COP8640C can be driven by a crystal clock. The crystal network is connected between the pins CKI and CKO.

Table I shows the component values required for various standard crystal values.

B. EXTERNAL OSCILLATOR

CKI can be driven by an external clock signal. CKO is available as a general purpose input and/or HALT restart control.

C. R/C OSCILLATOR

CKI is configured as a single pin RC controlled Schmitt trigger oscillator. CKO is available as a general purpose input and/or HALT restart control.

Table II shows the variation in the oscillator frequencies (due to the part) as functions of the R/C component values (R/C tolerances not included).

TABLE I. Crystal Oscillator Configuration, $T_A = 25^\circ\text{C}$, $V_{CC} = 5.0\text{V}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)
0	1	30	30-36	10
0	1	30	30-36	4
5.5	1	100	100	0.455

TABLE II. RC Oscillator Configuration, $T_A = 25^\circ\text{C}$, $V_{CC} = 5.0\text{V}$

R (k Ω)	C (pF)	CKI Freq. (MHz)	Instr. Cycle (μs)
3.3	82	2.2 to 2.7	3.7 to 4.6
5.6	100	1.1 to 1.3	7.4 to 9.0
6.8	100	0.9 to 1.1	8.8 to 10.8

Note: $3\text{k} \leq R \leq 200\text{k}$
 $50\text{ pF} \leq C \leq 200\text{ pF}$

Functional Description (Continued)

The COP8620C/COP8640C microcontroller has three mask options for configuring the clock input. The CKI and CKO pins are automatically configured upon selecting a particular option.

- Crystal/Resonator (CKI/10) CKO for crystal configuration
- External (CKI/10) CKO available as G7 input
- R/C (CKI/10) CKO available as G7 input

G7 can be used either as a general purpose input or as a control input to continue from the HALT mode.

CURRENT DRAIN

The total current drain of the chip depends on:

- 1) Oscillator operating mode—I1
- 2) Internal switching current—I2
- 3) Internal leakage current—I3
- 4) Output source current—I4
- 5) DC current caused by external input not at V_{CC} or GND—I5
- 6) EEPROM current during EE read operation. This current is active during 20% of the instruction cycle time—I6
- 7) EEPROM current during write operation—I7

Thus the total current drain, I_t is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5 + I_6 + I_7$$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw the least current when in the normal mode. The high speed mode will draw additional current. The R/C mode will draw the most. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

Where

C = equivalent capacitance of the chip.

V = operating voltage

f = CKI frequency

HALT MODE

The COP8620C/COP8640C supports a power saving mode of operation: HALT. The controller is placed in the HALT mode by setting the G7 data bit, alternatively the user can stop the clock input. In the HALT mode all internal processor activities including the clock oscillator are stopped. The fully static architecture freezes the state of the controller and retains all information until continuing. In the HALT mode, power requirements are minimal as it draws only leakage currents and output current. The applied voltage (V_{CC}) may be decreased down to V_r (minimum RAM retention voltage) without altering the state of the machine.

There are two ways to exit the HALT mode: via the RESET or by the CKO pin. A low on the RESET line reinitializes the microcontroller and starts executing from the address 0000H. A low to high transition on the CKO pin causes the microcontroller to continue with no reinitialization from the address following the HALT instruction. This also resets the G7 data bit.

INTERRUPTS

The COP8620C/COP8640C has a sophisticated interrupt structure to allow easy interface to the real world. There are three possible interrupt sources, as shown below.

A maskable interrupt on external G0 input (positive or negative edge sensitive under software control)

A maskable interrupt on timer underflow or timer capture

A non-maskable software/error interrupt on opcode zero

INTERRUPT CONTROL

The GIE (global interrupt enable) bit enables the interrupt function. This is used in conjunction with ENI and ENTI to select one or both of the interrupt sources. This bit is reset when interrupt is acknowledged.

ENI and ENTI bits select external and timer interrupt respectively. Thus the user can select either or both sources to interrupt the microcontroller when GIE is enabled.

IEDG selects the external interrupt edge (0 = rising edge, 1 = falling edge). The user can get an interrupt on both rising and falling edges by toggling the state of IEDG bit after each interrupt.

IPND and TPND bits signal which interrupt is pending. After interrupt is acknowledged, the user can check these two bits to determine which interrupt is pending. This permits the interrupts to be prioritized under software. The pending flags have to be cleared by the user. Setting the GIE bit high inside the interrupt subroutine allows nested interrupts.

The software interrupt does not reset the GIE bit. This means that the controller can be interrupted by other interrupt sources while servicing the software interrupt.

INTERRUPT PROCESSING

The interrupt, once acknowledged, pushes the program counter (PC) onto the stack and the stack pointer (SP) is decremented twice. The Global Interrupt Enable (GIE) bit is reset to disable further interrupts. The microcontroller then vectors to the address 00FFH and resumes execution from that address. This process takes 7 cycles to complete. At the end of the interrupt subroutine, any of the following three instructions return the processor back to the main program: RET, RETSK or RETI. Either one of the three instructions will pop the stack into the program counter (PC). The stack pointer is then incremented twice. The RETI instruction additionally sets the GIE bit to re-enable further interrupts.

Any of the three instructions can be used to return from a hardware interrupt subroutine. The RETSK instruction should be used when returning from a software interrupt subroutine to avoid entering an infinite loop.

Functional Description (Continued)

FIGURE 6. Interrupt Block Diagram

TL/DD/10366-11

DETECTION OF ILLEGAL CONDITIONS

The COP8620C/COP8640C incorporates a hardware mechanism that allows it to detect illegal conditions which may occur from coding errors, noise and 'brown out' voltage drop situations. Specifically it detects cases of executing out of undefined ROM area and unbalanced stack situations.

Reading an undefined RAM location returns 00 (hexadecimal) as its contents. The opcode for a software interrupt is also '00'. Thus a program accessing undefined ROM will cause a software interrupt.

Reading an undefined RAM location returns an FF (hexadecimal). The subroutine stack on the COP8620C/COP8640C grows down for each subroutine call. By initializing the stack pointer to the top of RAM (02F), the first unbalanced return instruction will cause the stack pointer to address undefined RAM. As a result the program will attempt to execute from FFFF (hexadecimal), which is an undefined ROM location and will trigger a software interrupt.

MICROWIRE/PLUS™

MICROWIRE/PLUS is a serial synchronous bidirectional communications interface. The MICROWIRE/PLUS capability enables the COP8620C/COP8640C to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, EEPROMS, etc.) and with other microcontrollers which support the MICROWIRE/PLUS interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 7 shows the block diagram of the MICROWIRE/PLUS interface.

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS interface with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE/PLUS interface with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. The SK clock rate is selected by the two bits, S0 and S1, in the CNTRL register. Table III details the different clock rates that may be selected.

TABLE III

S1	S0	SK Cycle Time
0	0	2t _C
0	1	4t _C
1	x	8t _C

where,

t_C is the instruction cycle clock.

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS arrangement to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. The COP8620C/COP8640C may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. Figure 8 shows how two COP8620C/COP8640C microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangement.

Master MICROWIRE/PLUS Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the COP8620C/COP8640C. The MICROWIRE/PLUS Master always initiates all data exchanges. (See Figure 8). The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table IV summarizes the bit settings required for Master mode of operation.

SLAVE MICROWIRE/PLUS OPERATION

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by appropriately setting up the Port G configuration register. Table IV summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated. (See Figure 8.)

Functional Description (Continued)

0	0	TRI-STATE	Ext. SK	SI	MICROWIRE Slave

TIMER/COUNTER

The COP8620C/COP8640C has a powerful 16-bit timer with an associated 16-bit register enabling them to perform extensive timer functions. The timer T1 and its register R1 are each organized as two 8-bit read/write registers. Control bits in the register CNTRL allow the timer to be started and stopped under software control. The timer-register pair can be operated in one of three possible modes. Table V details various timer operating modes and their requisite control settings.

TL/DD/10366-12

FIGURE 7. MICROWIRE/PLUS Block Diagram

MODE 1. TIMER WITH AUTO-LOAD REGISTER

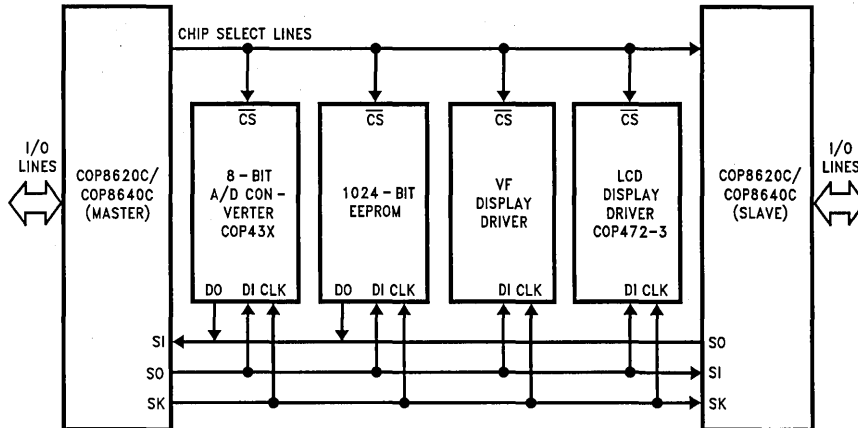

In this mode of operation, the timer T1 counts down at the instruction cycle rate. Upon underflow the value in the register R1 gets automatically reloaded into the timer which continues to count down. The timer underflow can be programmed to interrupt the microcontroller. A bit in the control register CNTRL enables the TIO (G3) pin to toggle upon timer underflows. This allow the generation of square-wave outputs or pulse width modulated outputs under software control. (See Figure 9)

MODE 2. EXTERNAL COUNTER

In this mode, the timer T1 becomes a 16-bit external event counter. The counter counts down upon an edge on the TIO pin. Control bits in the register CNTRL program the counter to decrement either on a positive edge or on a negative edge. Upon underflow the contents of the register R1 are automatically copied into the counter. The underflow can also be programmed to generate an interrupt. (See Figure 9)

MODE 3. TIMER WITH CAPTURE REGISTER

Timer T1 can be used to precisely measure external frequencies or events in this mode of operation. The timer T1 counts down at the instruction cycle rate. Upon the occurrence of a specified edge on the TIO pin the contents of the timer T1 are copied into the register R1. Bits in the control register CNTRL allow the trigger edge to be specified either as a positive edge or as a negative edge. In this mode the user can elect to be interrupted on the specified trigger edge. (See Figure 10.)

TL/DD/10366-13

FIGURE 9. Timer/Counter Auto Reload Mode Block Diagram

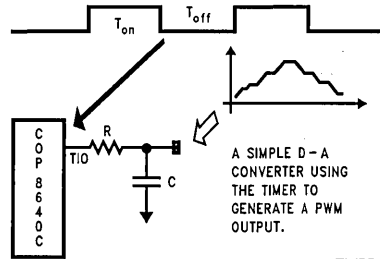

FIGURE 11. Timer Application

FIGURE 10. Timer Capture Mode Block Diagram

TIMER PWM APPLICATION

Figure 11 shows how a minimal component D/A converter can be built out of the Timer-Register pair in the Auto-Reload mode. The timer is placed in the "Timer with auto reload" mode and the TIO pin is selected as the timer output. At the outset the TIO pin is set high, the timer T1 holds the on time and the register R1 holds the signal off time. Setting TRUN bit starts the timer which counts down at the instruction cycle rate. The underflow toggles the TIO output and copies the off time into the timer, which continues to run. By alternately loading in the on time and the off time at each successive interrupt a PWM frequency can be easily generated.

Control Registers

CNTRL REGISTER (ADDRESS X'00EE)

The Timer and MICROWIRE/PLUS control register contains the following bits:

- S1 & S0 Select the MICROWIRE/PLUS clock divide-by
- IEDG External interrupt edge polarity select (0 = rising edge, 1 = falling edge)
- MSEL Enable MICROWIRE/PLUS functions SO and SK
- TRUN Start/Stop the Timer/Counter (1 = run, 0 = stop)
- TC3 Timer input edge polarity select (0 = rising edge, 1 = falling edge)
- TC2 Selects the capture mode
- TC1 Selects the timer mode

TC1	TC2	TC3	TRUN	MSEL	IEDG	S1	S0
BIT 7				BIT 0			

PSW REGISTER (ADDRESS X'00EF)

The PSW register contains the following select bits:

- GIE Global interrupt enable
- ENI External interrupt enable
- BUSY MICROWIRE/PLUS busy shifting
- IPND External interrupt pending
- ENTI Timer interrupt enable
- TPND Timer interrupt pending
- C Carry Flag
- HC Half carry Flag

HC	C	TPND	ENTI	IPND	BUSY	ENI	GIE
BIT 7				BIT 0			

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space.

Address	Contents
COP8620C/COP8640C	
00 to 2F	On Chip RAM Bytes
30 to 7F	Unused RAM Address Space (Reads as all Ones)
80 to BF	On Chip EEPROM (64 bytes)
C0 to CF	Expansion Space for I/O and Registers
D0 to DF	On Chip I/O and Registers
D0	Port L Data Register
D1	Port L Configuration Register
D2	Port L Input Pins (Read Only)
D3	Reserved for Port L
D4	Port G Data Register
D5	Port G Configuration Register
D6	Port G Input Pins (Read Only)
D7	Port I Input Pins (Read Only)
D8-DB	Reserved for Port C
DC	Port D Data Register
DD-DF	Reserved for Port D
E0 to EF	On Chip Functions and Registers
E0	EECR
E1-E8	Reserved
E9	MICROWIRE/PLUS Shift Register
EA	Timer Lower Byte
EB	Timer Upper Byte
EC	Timer Autoload Register Lower Byte
ED	Timer Autoload Register Upper Byte
EE	CNTRL Control Register
EF	PSW Register
F0 to FF	On Chip RAM Mapped as Registers
FC	X Register
FD	SP Register
FE	B Register

Reading unused memory locations below 7FH will return all ones. Reading other unused memory locations will return undefined data.

Addressing Modes

REGISTER INDIRECT

This is the "normal" mode of addressing for COP8620C/COP8640C. The operand is the memory addressed by the B register or X register.

DIRECT

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

IMMEDIATE

The instruction contains an 8-bit immediate field as the operand.

REGISTER INDIRECT (AUTO INCREMENT AND DECREMENT)

This is a register indirect mode that automatically increments or decrements the B or X register after executing the instruction.

RELATIVE

This mode is used for the JP instruction, the instruction field is added to the program counter to get the new program location. JP has a range of from -31 to +32 to allow a one byte relative jump (JP + 1 is implemented by a NOP instruction). There are no 'pages' when using JP, all 15 bits of PC are used.

Instruction Set

REGISTER AND SYMBOL DEFINITIONS

Registers

A	8-bit Accumulator register
B	8-bit Address register
X	8-bit Address register
SP	8-bit Stack pointer register
PC	15-bit Program counter register
PU	upper 7 bits of PC
PL	lower 8 bits of PC
C	1-bit of PSW register for carry
HC	Half Carry
GIE	1-bit of PSW register for global interrupt enable

Symbols

[B]	Memory indirectly addressed by B register
[X]	Memory indirectly addressed by X register
Mem	Direct address memory or [B]
MemI	Direct address memory or [B] or Immediate data
Imm	8-bit Immediate data
Reg	Register memory: addresses F0 to FF (Includes B, X and SP)
Bit	Bit number (0 to 7)
←	Loaded with
↔	Exchanged with

Option List

The COP8620C/COP8640C mask programmable options are listed out below. The options are programmed at the same time as the ROM pattern to provide the user with hardware flexibility to use a variety of oscillator configuration.

OPTION 1: CKI INPUT

- = 1 Crystal/Resonator (CKI/10) CKO for crystal configuration
- = 2 External (CKI/10) CKO available as G7 input
- = 3 R/C (CKI/10) CKO available as G7 input

OPTION 2: COP8620C/COP8640C BONDING

- = 1 28 pin DIP
- = 2 N/A
- = 3 20 pin DIP
- = 4 20 SO
- = 5 28 SO

The following option information is to be sent to National along with the EPROM.

Option Data

Option 1 Value is: __ CKI Input

Option 2 Value is: __ COP Bonding

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32k bytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, dis-

abled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed or ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bargraph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2k baud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS-232 serial interface cable.
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Pkg.	Voltage Range	Emulates
MHW-8640C20D5PC	20 DIP	4.5-5.5V	COP8642C, 8622C

Development Support

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM® PC-XT®, PC-AT® or compatible	424410527-001

SIMULATOR

The COP8 Designers' Toolkit is available for evaluating National Semiconductor's COP8 microcontroller family. The kit contains programmer's manuals, device datasheets, pocket reference guides, assembler and simulator which allow the user to write, test, debug and run code on an industry standard compatible PC. The simulator has a windowed user interface and can handle script files that simulate hardware inputs, interrupts and automatic command processing. The capture file feature enables the user to record to a file current cycle count and output port changes which are caused by the program under test.

Simulator Ordering Information

Part Number	Description	Manual
COP8-TOOL-KIT	COP8 Designer's Tool Kit Assembler and Simulator	420420270-001
		424420269-001

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications Group. The Dial-A-Helper is an Electronic Bulletin Board information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

Single Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP8640CMHD-X	X = 1: Crystal X = 2: External X = 3: R/C	28 DIP	Multi Chip Module (MCM), UV Erasable	COP8640C, 8620C
COP8640CMHEA-X	X = 1: Crystal X = 2: External X = 3: R/C	28 LCC	MCM (Same Footprint as 28 SO), UV Erasable	COP8640C, 8620C
COP8642CMHD-X	X = 1: Crystal X = 2: External X = 3: R/C	20 DIP	MCM, UV Erasable	COP8642C, 8622C

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator Board for 28 DIP and for use with Scrambler Boards	COP8640CMHD
COP8-SCRM-DIP	Scrambler Board for 20 DIP Socket	COP8642CMHD
COP8-SCRM-SBX	Scrambler Board for 28 LCC Socket	COP8640CMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler Board	COP8642CMHD COP8640CMHD

Development Support (Continued)

If the user has a PC with a communications package then files from the FILE SECTION can be down-loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP
Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

Voice: (408) 721-5582
Modem: (408) 739-1162
Baud: 300 or 1200 baud
Setup: Length: 8-Bit
Parity: None
Stop Bit: 1
Operation: 24 Hrs. 7 Days

COP680C/COP681C/COP880C/COP881C/ COP980C/COP981C Microcontrollers

General Description

The COP880C and COP881C are members of the COPSM microcontroller family. They are fully static parts, fabricated using double-metal silicon gate microCMOS technology. This low cost microcontroller is a complete microcomputer containing all system timing, interrupt logic, ROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUSSM serial I/O, a 16-bit timer/counter with capture register and a multi-sourced interrupt. Each I/O pin has software selectable options to adapt the COP880C and COP881C to the specific application. The part operates over a voltage range of 2.5 to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a 1 microsecond per instruction rate.

Features

- Low cost 8-bit microcontroller
- Fully static CMOS
- 1 μ s instruction time
- Low current drain
 - Low current static HALT mode (Typically < 1 μ A)
- Single supply operation: 2.5 to 6.0V
- 4096 bytes ROM/128 Bytes RAM

- 16-bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - Reset master clear
 - External interrupt with selectable edge
 - Timer interrupt or capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set, most instructions single byte
- BCD arithmetic instructions
- MICROWIRE PLUSSM serial I/O
- 44 PLCC, 36 I/O pins
- 40 DIP, 36 I/O pins
- 28 DIP and SO, 24 I/O pins
- Software selectable I/O options (TRI-STATE[®], push-pull, weak pull-up)
- Schmitt trigger inputs on Port G
- Temperature ranges: COP98XC/COP98XCH 0°C to 70°C, COP88XC -40°C to +85°C, COP68XC -55°C to +125°C.
- Form factor emulation devices
- Fully supported by National's development system

COP980C/COP981C**DC Electrical Characteristics** (Continued)

Note 1: Rate of voltage change must be less than 0.5V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L, C and G ports TRI-STATE and tied to ground, all outputs low and tied to ground.

Note 4: Pins G6 and $\overline{\text{RESET}}$ are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typ). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

Note 5: To maintain RAM integrity, the voltage must not be dropped or raised instantaneously.

AC Electrical Characteristics $0^{\circ}\text{C} < T_A < +70^{\circ}\text{C}$ unless otherwise specified

FIGURE 3

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

\overline{RESET} is the master reset input. See Reset description.

PORT I is an 8-bit Hi-Z input port.

PORT L is an 8-bit I/O port.

PORT C is a 4-bit I/O port.

Three memory locations are allocated for the L, G and C ports, one each for data register, configuration register and the input pins. Reading bits 4–7 of the C-Configuration register, data register, and input pins returns undefined data.

There are two registers associated with the L and C ports: a data register and a configuration register. Therefore, each L and C I/O bit can be individually configured under software control as shown below:

Config.	Data	Ports L and C Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

On the 28-pin part, it is recommended that all bits of Port C be configured as outputs.

PORT G is an 8-bit port with 6 I/O pins (G0–G5) and 2 input pins (G6, G7). All eight G-pins have Schmitt Triggers on the inputs.

There are two registers associated with the G port: a data register and a configuration register. Therefore, each G port bit can be individually configured under software control as shown below:

Config.	Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

Since G6 and G7 are input only pins, any attempt by the user to configure them as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. The COP880C will be placed in the HALT mode by writing to the G7 bit in the G-port data register.

Six pins of Port G have alternate features:

G0 INTR (an external interrupt)

G3 TIO (timer/counter input/output)

G4 SO (MICROWIRE serial data output)

G5 SK (MICROWIRE clock I/O)

G6 SI (MICROWIRE serial data input)

G7 CKO crystal oscillator output (selected by mask option) or HALT restart input (general purpose input)

Pins G1 and G2 currently do not have any alternate functions.

PORT D is an 8-bit output port that is preset high when \overline{RESET} goes low. Care must be exercised with the D2 pin operation. At \overline{RESET} , the external loads on this pin must ensure that the output voltages stay above 0.9 V_{CC} to prevent the chip from entering special modes. Also, keep the external loading on D2 to less than 1000 pF.

Functional Description

Figure 1 shows the block diagram of the internal architecture. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device.

ALU AND CPU REGISTERS

The ALU can do an 8-bit addition, subtraction, logical or shift operation in one cycle time.

There are five CPU registers:

A is the 8-bit Accumulator register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is the 8-bit address register, can be auto incremented or decremented.

X is the 8-bit alternate address register, can be incremented or decremented.

SP is the 8-bit stack pointer, points to subroutine stack (in RAM).

B, X and SP registers are mapped into the on chip RAM. The B and X registers are used to address the on chip RAM. The SP register is used to address the stack in RAM during subroutine calls and returns.

PROGRAM MEMORY

Program memory for the COP880C/COP881C consists of 4096 bytes of ROM. These bytes may hold program instructions or constant data. The program memory is addressed by the 15-bit program counter (PC). ROM can be indirectly read by the LAID instruction for table lookup.

DATA MEMORY

The data memory address space includes on chip RAM, I/O and registers. Data memory is addressed directly by the instruction or indirectly by the B, X and SP registers.

The COP880C/COP881C has 128 bytes of RAM. Sixteen bytes of RAM are mapped as "registers" that can be loaded immediately, decremented or tested. Three specific registers: B, X and SP are mapped into this space, the other bytes are available for general usage.

The instruction set permits any bit in memory to be set, reset or tested. All I/O and registers (except the A & PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested. A is not memory mapped, but bit operations can be still performed on it.

RESET

The \overline{RESET} input when pulled low initializes the microcontroller. Initialization will occur whenever the \overline{RESET} input is pulled low. Upon initialization, the ports L, G and C are placed in the TRI-STATE mode and the Port D is set high. The PC, PSW and CNTRL registers are cleared. The data and configuration registers for Ports L, G and C are cleared.

The external RC network shown in *Figure 4* should be used to ensure that the \overline{RESET} pin is held low until the power supply to the chip stabilizes.

TL/DD/10802-6

OSCILLATOR CIRCUITS

Figure 5 shows the three clock oscillator configurations available for the COP880C and COP881C.

A. CRYSTAL OSCILLATOR

The COP880C/COP881C can be driven by a crystal clock. The crystal network is connected between the pins CKI and CKO.

Table I shows the component values required for various standard crystal values.

B. EXTERNAL OSCILLATOR

CKI can be driven by an external clock signal. CKO is available as a general purpose input and/or HALT restart control.

C. R/C OSCILLATOR

CKI is configured as a single pin RC controlled Schmitt trigger oscillator. CKO is available as a general purpose input and/or HALT restart control.

Table II shows the variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/10802-7

FIGURE 5. Crystal and R-C Connection Diagrams

OSCILLATOR MASK OPTIONS

The COP880C and COP881C can be driven by clock inputs between DC and 10 MHz.

TABLE I. Crystal Oscillator Configuration, $T_A = 25^\circ\text{C}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)	Conditions
0	1	30	30-36	10	$V_{CC} = 5V$
0	1	30	30-36	4	$V_{CC} = 2.5V$
5.6	1	200	100-150	0.455	$V_{CC} = 5V$

TABLE II. RC Oscillator Configuration, $T_A = 25^\circ\text{C}$

R (k Ω)	C (pF)	CKI Freq. (MHz)	Instr. Cycle (μs)	Conditions
3.3	82	2.2 to 2.7	3.7 to 4.6	$V_{CC} = 5V$
5.6	100	1.1 to 1.3	7.4 to 9.0	$V_{CC} = 5V$
6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5V$

Note: (R/C Oscillator Configuration): $3k \leq R \leq 200k$, $50 \text{ pF} \leq C \leq 200 \text{ pF}$.

Functional Description (Continued)

The COP880C and COP881C microcontrollers have five mask options for configuring the clock input. The CKI and CKO pins are automatically configured upon selecting a particular option.

- Crystal (CKI/10); CKO for crystal configuration
- External (CKI/10); CKO available as G7 input
- R/C (CKI/10); CKO available as G7 input

G7 can be used either as a general purpose input or as a control input to continue from the HALT mode.

CURRENT DRAIN

The total current drain of the chip depends on:

- 1) Oscillator operating mode— I_1
- 2) Internal switching current— I_2
- 3) Internal leakage current— I_3
- 4) Output source current— I_4
- 5) DC current caused by external input not at V_{CC} or GND — I_5

Thus the total current drain, I_t is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5$$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw the least current when in the normal mode. The high speed mode will draw additional current. The R/C mode will draw the most. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

Where

C = equivalent capacitance of the chip.

V = operating voltage

f = CKI frequency

HALT MODE

The COP880C and COP881C support a power saving mode of operation: HALT. The controller is placed in the HALT mode by setting the G7 data bit, alternatively the user can stop the clock input. In the HALT mode all internal processor activities including the clock oscillator are stopped. The fully static architecture freezes the state of the controller and retains all information until continuing. In the HALT mode, power requirements are minimal as it draws only leakage currents and output current. The applied voltage (V_{CC}) may be decreased down to V_r (minimum RAM retention voltage) without altering the state of the machine.

There are two ways to exit the HALT mode: via the \overline{RESET} or by the CKO pin. A low on the \overline{RESET} line reinitializes the microcontroller and starts executing from the address

0000H. A low to high transition on the CKO pin causes the microcontroller to continue with no reinitialization from the address following the HALT instruction. This also resets the G7 data bit.

INTERRUPTS

The COP880C and COP881C have a sophisticated interrupt structure to allow easy interface to the real world. There are three possible interrupt sources, as shown below.

A maskable interrupt on external G0 input (positive or negative edge sensitive under software control)

A maskable interrupt on timer underflow or timer capture

A non-maskable software/error interrupt on opcode zero

INTERRUPT CONTROL

The GIE (global interrupt enable) bit enables the interrupt function. This is used in conjunction with ENI and ENTI to select one or both of the interrupt sources. This bit is reset when interrupt is acknowledged.

ENI and ENTI bits select external and timer interrupt respectively. Thus the user can select either or both sources to interrupt the microcontroller when GIE is enabled.

IEDG selects the external interrupt edge (0 = rising edge, 1 = falling edge). The user can get an interrupt on both rising and falling edges by toggling the state of IEDG bit after each interrupt.

IPND and TPND bits signal which interrupt is pending. After interrupt is acknowledged, the user can check these two bits to determine which interrupt is pending. This permits the interrupts to be prioritized under software. The pending flags have to be cleared by the user. Setting the GIE bit high inside the interrupt subroutine allows nested interrupts.

The software interrupt does not reset the GIE bit. This means that the controller can be interrupted by other interrupt sources while servicing the software interrupt.

INTERRUPT PROCESSING

The interrupt, once acknowledged, pushes the program counter (PC) onto the stack and the stack pointer (SP) is decremented twice. The Global Interrupt Enable (GIE) bit is reset to disable further interrupts. The microcontroller then vectors to the address 00FFH and resumes execution from that address. This process takes 7 cycles to complete. At the end of the interrupt subroutine, any of the following three instructions return the processor back to the main program: RET, RETSK or RETI. Either one of the three instructions will pop the stack into the program counter (PC). The stack pointer is then incremented twice. The RETI instruction additionally sets the GIE bit to re-enable further interrupts.

Any of the three instructions can be used to return from a hardware interrupt subroutine. The RETSK instruction should be used when returning from a software interrupt subroutine to avoid entering an infinite loop.

Functional Description (Continued)

FIGURE 6. Interrupt Block Diagram

TL/DD/10802-8

DETECTION OF ILLEGAL CONDITIONS

The COP880C and COP881C incorporate a hardware mechanism that allows it to detect illegal conditions which may occur from coding errors, noise and 'brown out' voltage drop situations. Specifically it detects cases of executing out of undefined ROM area and unbalanced stack situations.

Reading an undefined ROM location returns 00 (hexadecimal) as its contents. The opcode for a software interrupt is also '00'. Thus a program accessing undefined ROM will cause a software interrupt.

Reading an undefined RAM location returns an FF (hexadecimal). The subroutine stack on the COP880C and COP881C grows down for each subroutine call. By initializing the stack pointer to the top of RAM, the first unbalanced return instruction will cause the stack pointer to address undefined RAM. As a result the program will attempt to execute from FFFF (hexadecimal), which is an undefined ROM location and will trigger a software interrupt.

MICROWIRE/PLUS™

MICROWIRE/PLUS is a serial synchronous bidirectional communications interface. The MICROWIRE/PLUS capability enables the COP880C and COP881C to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, EEPROMS, etc.) and with other microcontrollers which support the MICROWIRE/PLUS interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 7 shows the block diagram of the MICROWIRE/PLUS interface.

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS interface with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE/PLUS interface with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. The SK clock rate is selected by the two bits, S0 and S1, in the CNTRL register. Table III details the different clock rates that may be selected.

TABLE III

S1	S0	SK Cycle Time
0	0	2t _C
0	1	4t _C
1	x	8t _C

where,

t_C is the instruction cycle clock.

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS arrangement to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. The COP880C and COP881C may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. Figure 8 shows how two COP880C microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangement.

Master MICROWIRE/PLUS Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the COP880C. The MICROWIRE/PLUS Master always initiates all data exchanges. (See Figure 8). The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table IV summarizes the bit settings required for Master mode of operation.

SLAVE MICROWIRE/PLUS OPERATION

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by appropriately setting up the Port G configuration register. Table IV summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated. (See Figure 8.)

Functional Description (Continued)

TABLE IV

G4 Config. Bit	G5 Config. Bit	G4 Fun.	G5 Fun.	G6 Fun.	Operation
1	1	SO	Int. SK	SI	MICROWIRE Master

1	0	SO	Ext. SK	SI	MICROWIRE Slave
0	0	TRI-STATE	Ext. SK	SI	MICROWIRE Slave

TIMER/COUNTER

The COP880C and COP881C have a powerful 16-bit timer with an associated 16-bit register enabling them to perform extensive timer functions. The timer T1 and its register R1 are each organized as two 8-bit read/write registers. Control bits in the register CNTRL allow the timer to be started and stopped under software control. The timer-register pair can be operated in one of three possible modes. Table V details various timer operating modes and their requisite control settings.

TL/DD/10802-9

FIGURE 7. MICROWIRE/PLUS Block Diagram

MODE 1. TIMER WITH AUTO-LOAD REGISTER

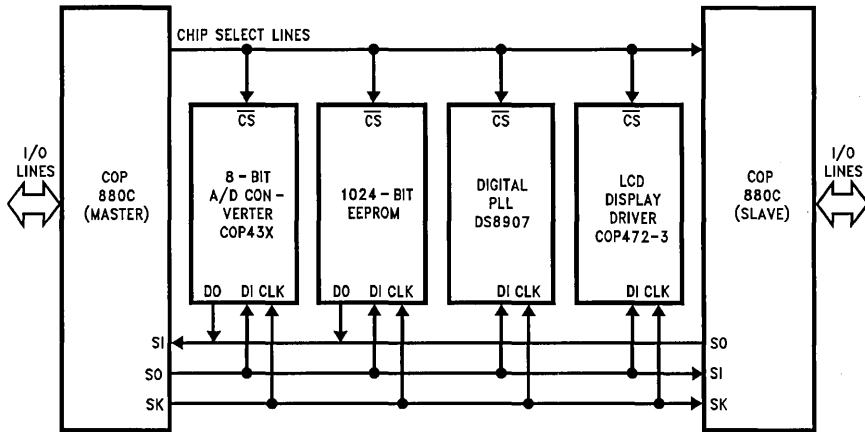

In this mode of operation, the timer T1 counts down at the instruction cycle rate. Upon underflow the value in the register R1 gets automatically reloaded into the timer which continues to count down. The timer underflow can be programmed to interrupt the microcontroller. A bit in the control register CNTRL enables the TIO (G3) pin to toggle upon timer underflows. This allows the generation of square-wave outputs or pulse width modulated outputs under software control. (See Figure 9.)

MODE 2. EXTERNAL COUNTER

In this mode, the timer T1 becomes a 16-bit external event counter. The counter counts down upon an edge on the TIO pin. Control bits in the register CNTRL program the counter to decrement either on a positive edge or on a negative edge. Upon underflow the contents of the register R1 are automatically copied into the counter. The underflow can also be programmed to generate an interrupt. (See Figure 9)

MODE 3. TIMER WITH CAPTURE REGISTER

Timer T1 can be used to precisely measure external frequencies or events in this mode of operation. The timer T1 counts down at the instruction cycle rate. Upon the occurrence of a specified edge on the TIO pin the contents of the timer T1 are copied into the register R1. Bits in the control register CNTRL allow the trigger edge to be specified either as a positive edge or as a negative edge. In this mode the user can elect to be interrupted on the specified trigger edge. (See Figure 10.)

FIGURE 9. Timer/Counter Auto Reload Mode Block Diagram

FIGURE 10. Timer Capture Mode Block Diagram

TIMER PWM APPLICATION

Figure 11 shows how a minimal component D/A converter can be built out of the Timer-Register pair in the Auto-Reload mode. The timer is placed in the "Timer with auto reload" mode and the TIO pin is selected as the timer output. At the outset the TIO pin is set high, the timer T1 holds the on time and the register R1 holds the signal off time. Setting TRUN bit starts the timer which counts down at the instruction cycle rate. The underflow toggles the TIO output and copies the off time into the timer, which continues to run. By alternately loading in the on time and the off time at each successive interrupt a PWM frequency can be easily generated.

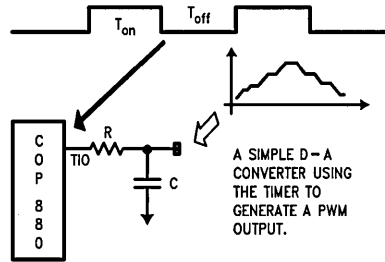

FIGURE 11. Timer Application

TL/DD/10802-13

Control Registers

CNTRL REGISTER (ADDRESS X'00EE)

The Timer and MICROWIRE/PLUS control register contains the following bits:

- S1 & S0 Select the MICROWIRE/PLUS clock divide-by
- IEDG External interrupt edge polarity select
(0 = rising edge, 1 = falling edge)
- MSEL Enable MICROWIRE/PLUS functions SO and SK
- TRUN Start/Stop the Timer/Counter (1 = run, 0 = stop)
- TC3 Timer input edge polarity select (0 = rising edge, 1 = falling edge)
- TC2 Selects the capture mode
- TC1 Selects the timer mode

TC1	TC2	TC3	TRUN	MSEL	IEDG	S1	S0
BIT 7							BIT 0

PSW REGISTER (ADDRESS X'00EF)

The PSW register contains the following select bits:

- GIE Global interrupt enable
- ENI External interrupt enable
- BUSY MICROWIRE/PLUS busy shifting
- IPND External interrupt pending
- ENTI Timer interrupt enable
- TPND Timer interrupt pending
- C Carry Flag
- HC Half carry Flag

HC	C	TPND	ENTI	IPND	BUSY	ENI	GIE
Bit 7							Bit 0

Addressing Modes

REGISTER INDIRECT

This is the "normal" mode of addressing for COP880C and COP881C. The operand is the memory addressed by the B register or X register.

DIRECT

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

IMMEDIATE

The instruction contains an 8-bit immediate field as the operand.

REGISTER INDIRECT (AUTO INCREMENT AND DECREMENT)

This is a register indirect mode that automatically increments or decrements the B or X register after executing the instruction.

RELATIVE

This mode is used for the JP instruction, the instruction field is added to the program counter to get the new program location. JP has a range of from -31 to +32 to allow a one byte relative jump (JP + 1 is implemented by a NOP instruction). There are no 'pages' when using JP, all 15 bits of PC are used.

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space.

Address	Contents
00 to 6F	On Chip RAM Bytes
70 to 7F	Unused RAM Address Space (Reads as all Ones)
80 to BF	Expansion Space for on Chip EERAM
C0 to CF	Expansion Space for I/O and Registers
D0 to DF	On Chip I/O and Registers
D0	Port L Data Register
D1	Port L Configuration Register
D2	Port L Input Pins (Read Only)
D3	Reserved for Port L
D4	Port G Data Register
D5	Port G Configuration Register
D6	Port G Input Pins (Read Only)
D7	Port I Input Pins (Read Only)
D8	Port C Data Register
D9	Port C Configuration Register
DA	Port C Input Pins (Read Only)
DB	Reserved for Port C
DC	Port D Data Register
DD-DF	Reserved for Port D
E0 to EF	On Chip Functions and Registers
E0-E7	Reserved for Future Parts
E8	Reserved
E9	MICROWIRE/PLUS Shift Register
EA	Timer Lower Byte
EB	Timer Upper Byte
EC	Timer Autoload Register Lower Byte
ED	Timer Autoload Register Upper Byte
EE	CNTRL Control Register
EF	PSW Register
F0 to FF	On Chip RAM Mapped as Registers
FC	X Register
FD	SP Register
FE	B Register

Reading unused memory locations below 7FH will return all ones. Reading other unused memory locations will return undefined data.

Bits 3-0

where, i is the immediate data Md is a directly addressed memory location * is an unused opcode (see following table)

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instruction taking two bytes).

Most single instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

BYTES and CYCLES per INSTRUCTION

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

	[B]	Direct	Immed.
ADD	1/1	3/4	2/2
ADC	1/1	3/4	2/2
SUBC	1/1	3/4	2/2

Option List

The COP880C/COP881C mask programmable options are listed out below. The options are programmed at the same time as the ROM pattern to provide the user with hardware flexibility to use a variety of oscillator configuration.

OPTION 1: CKI INPUT

- = 1 Crystal (CKI/10) CKO for crystal configuration
- = 2 External (CKI/10) CKO available as G7 input
- = 3 R/C (CKI/10) CKO available as G7 input

OPTION 2: COP880C/COP881C BONDING

- = 1 44-Pin PLCC
- = 2 40-Pin DIP
- = 3 28-Pin SO
- = 4 28-Pin DIP

The following option information is to be sent to National along with the EPROM.

Option Data

- Option 1 Value__is: CKI Input
- Option 2 Value__is: COP Bonding

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real-time, full-speed emulation up to 10 MHz, 32 kbytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bargraph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy-to-use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS-232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MHW-880C28D5PC	28 DIP	4.5V–5.5V	COP820C, 840C, 881C, 8781C
MHW-880C28DWPC	28 DIP	2.5V–6.0V	COP820C, 840C, 881C, 8781C
MHW-880C40D5PC	40 DIP	4.5V–5.5V	COP880C, 8780C
MHW-880C40DWPC	40 DIP	2.5V–6.0V	COP880C, 8780C
MHW-880C44D5PC	44 PLCC	4.5V–5.5V	COP880C, 8780C
MHW-880C44DWPC	44 PLCC	2.5V–6.0V	COP880C, 8780C

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM PC-XT®, PC-AT®, or compatible	424410527-001

COP880C/COP881C/COP880C/COP881C/COP980C/COP981C

Development Support (Continued)

SINGLE-CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. Two types of single-chip emulators are available: Multi-Chip Module emulators, which combine the microcontroller-die and an EPROM-die in one package,

and emulators where the microcontroller's standard ROM has been replaced with an on-chip EPROM. For more detailed information, refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

Single-Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP880CMHEL-X	X = 1: Crystal X = 2: External X = 3: R/C	44 LDCC	Multi-Chip Module (MCM), UV Erasable	COP880C
COP880CMHD-X	X = 1: Crystal X = 2: External X = 3: R/C	40 DIP	MCM, UV Erasable	COP880C
COP881CMHD-X	X = 1: Crystal X = 2: External X = 3: R/C	28 DIP	MCM, UV Erasable	COP881C
COP881CMHEA-X	X = 1: Crystal X = 2: External X = 3: R/C	28 LCC	MCM (Same Footprint as 28 SO), UV Erasable	COP881C
COP8780CV	Programmable	44 PLCC	One-Time Programmable (OTP)	COP880C
COP8780CEL	Programmable	44 LDCC	UV Erasable	COP880C
COP8780CN	Programmable	40 DIP	OTP	COP880C
COP8780CJ	Programmable	40 DIP	UV Erasable	COP880C
COP8781CN	Programmable	28 DIP	OTP	COP881C
COP8781CJ	Programmable	28 DIP	UV Erasable	COP881C
COP8781CWM	Programmable	28 SO	OTP	COP881C
COP8781CMC	Programmable	28 SO	UV Erasable	COP881C

PROGRAMMING SUPPORT

Programming of the single-chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single-chip emulator and vice versa. Data I/O supports COP8 emulator

device programming with its UniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 FAX: (206) 882-1043

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator Board for 28 DIP Multi-Chip Module (MCM) and for Use with Scrambler Boards	COP881CMHD
COP8-SCRM-DIP	MCM Scrambler Board for 40 DIP Socket	COP880CMHD
COP8-SCRM-PCC	MCM Scrambler Board for 44 PLCC/LDCC	COP880CMHEL
COP8-SCRM-SBX	MCM Scrambler Board for 28 LCC Socket	COP881CMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler Board	COP881CMHD, COP880CMHD
COP8-PRGM-PCC	Duplicator Board with COP8-SCRM-PCC Scrambler Board	COP880CMEL, COP881CMHD
COP8-PRGM-87A	Duplicator Board with COP87XX Scrambler for 28 DIP, 28 SO, and 40 DIP	COP8781CN, COP8781CJ, COP8781CWM, COP8781CMC, COP8780CN, COP8780CJ
COP8-PRGM-87B	Duplicator Board with COP87XX Scrambler for 44 PLCC/LDCC	COP8780CV, COP8780CEL

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications Group. The Dial-A-Helper is an Electronic Bulletin Board information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down-loaded to disk for later use.

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to, or under extraordinary circumstances he can arrange for us to actually take control of his system via modem for debugging purposes.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 baud

Setup: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs. 7 Days

COP688CL/COP684CL, COP888CL/COP884CL, COP988CL/COP984CL Single-Chip microCMOS Microcontroller

General Description

The COP888 family of microcontrollers uses an 8-bit single chip core architecture fabricated with National Semiconductor's M²CMOS™ process technology. The COP888CL is a member of this expandable 8-bit core processor family of microcontrollers. (Continued)

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μ s instruction cycle time
- 4096 bytes on-board ROM
- 128 bytes on-board RAM
- Single supply operation: 2.5V–6V
- MICROWIRE/PLUS™ serial I/O
- WATCHDOG™ and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- Ten multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Timers TA, TB (Each with 2 Interrupts)
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - Default VIS
- Two 16-bit timers, each with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Versatile instruction set
- True bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 PLCC or 40 N or 28 N or 28 SO
 - 44 PLCC with 39 I/O pins
 - 40 N with 33 I/O pins
 - 28 SO or 28 N, each with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Temperature ranges: 0°C to +70°C,
–40°C to +85°C,
–55°C to +125°C
- Single chip hybrid emulation device COP888CLMH
- Real time emulation and full program debug offered by National's Development Systems

Block Diagram

FIGURE 1. COP888CL Block Diagram

TL/DD/9766–1

General Description (Continued)

It is a fully static part, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS serial I/O, two 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), and two power savings modes (HALT and IDLE), both with a multi-

sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The COP888CL operates over a voltage range of 2.5V to 6V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Voltage at Any Pin	-0.3V to V_{CC} + 0.3V
Total Current into V_{CC} Pin (Source)	100 mA

Total Current out of GND Pin (Sink)	110 mA
Storage Temperature Range	-65°C to +140°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

Note 4: Parameter sampled (not 100% tested).

Note 5: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Voltage at Any Pin	-0.3V to V_{CC} + 0.3V
Total Current into V_{CC} Pin (Source)	100 mA

Total Current out of GND Pin (Sink)	110 mA
Storage Temperature Range	-65°C to +140°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics COP88XCL: -40°C ≤ T_A ≤ +85°C unless otherwise specified

AC Electrical Characteristics (Continued)

FIGURE 2. MICROWIRE/PLUS Timing

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The COP888CL contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input (Schmitt trigger inputs on ports G and L), output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. (See the COP888CL memory map for the various addresses associated with the I/O ports.) Figure 3 shows the I/O port configurations for the COP888CL. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

FIGURE 3. I/O Port Configurations

PORT L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

Port L supports Multi-Input Wakeup (MIWU) on all eight pins. L4 and L5 are used for the timer input functions T2A and T2B.

Port L has the following alternate features:

- L0 MIWU
- L1 MIWU
- L2 MIWU
- L3 MIWU
- L4 MIWU or T2A
- L5 MIWU or T2B
- L6 MIWU
- L7 MIWU

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOOUT WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin, but is also used to bring the device out of HALT mode with a low to high transition. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin or general purpose input (R/C clock configuration), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE™ Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Pin Descriptions (Continued)

Port G has the following dedicated functions:

- G1 WDOUT WATCHDOG and/or Clock Monitor dedicated output
- G7 CKO Oscillator dedicated output or general purpose input

Port C is an 8-bit I/O port. The 40-pin device does not have a full complement of Port C pins. The unavailable pins are not terminated. A read operation for these unterminated pins will return unpredictable values.

Port I is an 8-bit Hi-Z input port. The 40-pin device does not have a full complement of Port I pins. Pins 15 and 16 on this package must be connected to GND.

The 28-pin device has four I pins (I0, I1, I4, I5). The user should pay attention when reading port I to the fact that I4 and I5 are in bit positions 4 and 5 rather than 2 and 3.

The unavailable pins (I4–I7) are not terminated i.e., they are floating. A read operation for these unterminated pins will return unpredictable values. The user must ensure that the software takes into account by either masking or restricting the accesses to bit operations. The unterminated port I pins will draw power only when addressed.

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Functional Description

The architecture of the COP888CL is modified Harvard architecture. With the Harvard architecture, the control store program memory (ROM) is separated from the data store memory (RAM). Both ROM and RAM have their own separate addressing space with separate address buses. The COP888CL architecture, though based on Harvard architecture, permits transfer of data from ROM to RAM.

CPU REGISTERS

The CPU can do an 8-bit addition, subtraction, logical or shift operation in one instruction (t_c) cycle time.

There are five CPU registers:

A is the 8-bit Accumulator Register

PC is the 15-bit Program Counter Register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is an 8-bit RAM address pointer, which can be optionally post auto incremented or decremented.

X is an 8-bit alternate RAM address pointer, which can be optionally post auto incremented or decremented.

SP is the 8-bit stack pointer, which points to the subroutine/interrupt stack (in RAM). The SP is initialized to RAM address 06F with reset.

All the CPU registers are memory mapped with the exception of the Accumulator (A) and the Program Counter (PC).

PROGRAM MEMORY

Program memory for the COP888CL consists of 4096 bytes of ROM. These bytes may hold program instructions or constant data (data tables for the LAID instruction, jump vectors

for the JID instruction, and interrupt vectors for the VIS instruction). The program memory is addressed by the 15-bit program counter (PC). All interrupts in the COP888CL vector to program memory location 0FF Hex.

DATA MEMORY

The data memory address space includes the on-chip RAM and data registers, the I/O registers (Configuration, Data and Pin), the control registers, the MICROWIRE/PLUS SIO shift register, and the various registers, and counters associated with the timers (with the exception of the IDLE timer). Data memory is addressed directly by the instruction or indirectly by the B, X and SP pointers.

The COP888CL has 128 bytes of RAM. Sixteen bytes of RAM are mapped as "registers" at addresses 0F0 to 0FF Hex. These registers can be loaded immediately, and also decremented and tested with the DRSZ (decrement register and skip if zero) instruction. The memory pointer registers X, SP, and B are memory mapped into this space at address locations 0FC to 0FE Hex respectively, with the other registers (other than reserved register 0FF) being available for general usage.

The instruction set of the COP888CL permits any bit in memory to be set, reset or tested. All I/O and registers on the COP888CL (except A and PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested. The accumulator (A) bits can also be directly and individually tested.

Reset

The RESET input when pulled low initializes the microcontroller. Initialization will occur whenever the RESET input is pulled low. Upon initialization, the data and configuration registers for Ports L, G, and C are cleared, resulting in these Ports being initialized to the TRI-STATE mode. Pin G1 of the G Port is an exception (as noted below) since pin G1 is dedicated as the WATCHDOG and/or Clock Monitor error output pin. Port D is initialized high with RESET. The PC, PSW, CNTRL, ICNTRL, and T2CNTRL control registers are cleared. The Multi-Input Wakeup registers WKEN, WKEDG, and WKPND are cleared. The Stack Pointer, SP, is initialized to 06F Hex.

The COP888CL comes out of reset with both the WATCHDOG logic and the Clock Monitor detector armed, and with both the WATCHDOG service window bits set and the Clock Monitor bit set. The WATCHDOG and Clock Monitor detector circuits are inhibited during reset. The WATCHDOG service window bits are initialized to the maximum WATCHDOG service window of 64k t_c clock cycles. The Clock Monitor bit is initialized high, and will cause a Clock Monitor error following reset if the clock has not reached the minimum specified frequency at the termination of reset. A Clock Monitor error will cause an active low error output on pin G1. This error output will continue until 16–32 t_c clock cycles following the clock frequency reaching the minimum specified value, at which time the G1 output will enter the TRI-STATE mode.

The external RC network shown in *Figure 4* should be used to ensure that the RESET pin is held low until the power supply to the chip stabilizes.

Reset (Continued)

TL/DD/9766-7

$RC > 5 \times$ Power Supply Rise Time

FIGURE 4. Recommended Reset Circuit

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Figure 5 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table A shows the component values required for various standard crystal values.

R/C OSCILLATOR

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart pin.

Table B shows the variation in the oscillator frequencies as functions of the component (R and C) values.

R (k Ω)	C (pF)	CKI Freq (MHz)	Instr. Cycle (μs)	Conditions
3.3	82	2.2 to 2.7	3.7 to 4.6	$V_{CC} = 5V$
5.6	100	1.1 to 1.3	7.4 to 9.0	$V_{CC} = 5V$
6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5V$

Note: $3k \leq R \leq 200k$, $50 \text{ pF} \leq C \leq 200 \text{ pF}$

Current Drain

The total current drain of the chip depends on:

1. Oscillator operation mode—I1
2. Internal switching current—I2
3. Internal leakage current—I3
4. Output source current—I4
5. DC current caused by external input not at V_{CC} or GND—I5
6. Clock Monitor current when enabled—I6

Thus the total current drain, It, is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5 + I_6$$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw more current as the CKI input frequency increases up to the maximum 10 MHz value. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

where C = equivalent capacitance of the chip
 V = operating voltage
 f = CKI frequency

Control Registers

CNTRL Register (Address X'00EE)

The Timer1 (T1) and MICROWIRE/PLUS control register contains the following bits:

- SL1 & SL0 Select the MICROWIRE/PLUS clock divide by (00 = 2, 01 = 4, 1x = 8)
- IEDG External interrupt edge polarity select (0 = Rising edge, 1 = Falling edge)
- MSEL Selects G5 and G4 as MICROWIRE/PLUS signals SK and SO respectively

Control Registers (Continued)

T1C0	Timer T1 Start/Stop control in timer modes 1 and 2
	Timer T1 Underflow Interrupt Pending Flag in timer mode 3
T1C1	Timer T1 mode control bit
T1C2	Timer T1 mode control bit
T1C3	Timer T1 mode control bit

T1C3	T1C2	T1C1	T1C0	MSEL	IEDG	SL1	SL0
Bit 7							Bit 0

PSW Register (Address X'00EF)

The PSW register contains the following select bits:

GIE	Global interrupt enable (enables interrupts)
EXEN	Enable external interrupt
BUSY	MICROWIRE/PLUS busy shifting flag
EXPND	External interrupt pending
T1ENA	Timer T1 Interrupt Enable for Timer Underflow or T1A Input capture edge
T1PNDA	Timer T1 Interrupt Pending Flag (Autoreload RA in mode 1, T1 Underflow in Mode 2, T1A capture edge in mode 3)
C	Carry Flag
HC	Half Carry Flag

HC	C	T1PNDA	T1ENA	EXPND	BUSY	EXEN	GIE
Bit 7							Bit 0

The Half-Carry bit is also affected by all the instructions that affect the Carry flag. The SC (Set Carry) and RC (Reset Carry) instructions will respectively set or clear both the carry flags. In addition to the SC and RC instructions, ADC, SUBC, RRC and RLC instructions affect the carry and Half Carry flags.

ICNTRL Register (Address X'00E8)

The ICNTRL register contains the following bits:

T1ENB	Timer T1 Interrupt Enable for T1B Input capture edge
T1PNDB	Timer T1 Interrupt Pending Flag for T1B capture edge

μ WEN	Enable MICROWIRE/PLUS interrupt
μ WPND	MICROWIRE/PLUS interrupt pending
T0EN	Timer T0 Interrupt Enable (Bit 12 toggle)
T0PND	Timer T0 Interrupt pending
LPEN	L Port Interrupt Enable (Multi-Input Wakeup/Interrupt)

Bit 7 could be used as a flag

Unused	LPEN	T0PND	T0EN	μ WPND	μ WEN	T1PNDB	T1ENB
Bit 7							Bit 0

T2CNTRL Register (Address X'00C6)

The T2CNTRL register contains the following bits:

T2ENB	Timer T2 Interrupt Enable for T2B Input capture edge
T2PNDB	Timer T2 Interrupt Pending Flag for T2B capture edge
T2ENA	Timer T2 Interrupt Enable for Timer Underflow or T2A Input capture edge
T2PNDA	Timer T2 Interrupt Pending Flag (Autoreload RA in mode 1, T2 Underflow in mode 2, T2A capture edge in mode 3)
T2C0	Timer T2 Start/Stop control in timer modes 1 and 2
	Timer T2 Underflow Interrupt Pending Flag in timer mode 3
T2C1	Timer T2 mode control bit
T2C2	Timer T2 mode control bit
T2C3	Timer T2 mode control bit

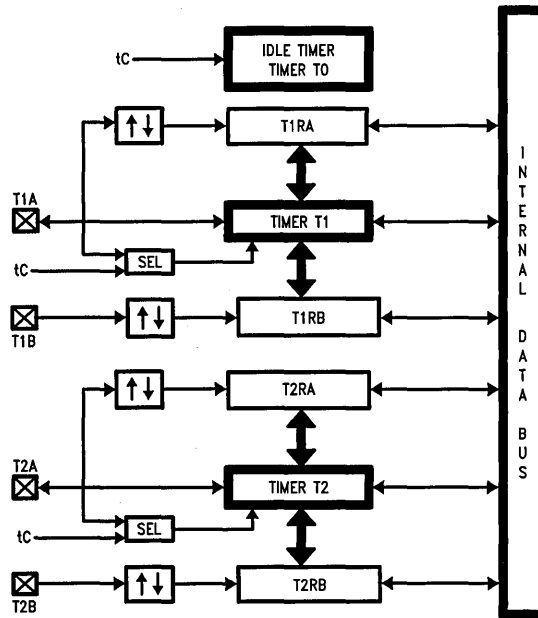

T2C3	T2C2	T2C1	T2C0	T2PNDA	T2ENA	T2PNDB	T2ENB
Bit 7							Bit 0

Timers

The COP888CL contains a very versatile set of timers (T0, T1, T2). All timers and associated autoreload/capture registers power up containing random data.

Figure 6 shows a block diagram for the timers on the COP888CL.

Timers (Continued)

TL/DD/9766-11

FIGURE 6. Timers for the COP888CL

TIMER T0 (IDLE TIMER)

The COP888CL supports applications that require maintaining real time and low power with the IDLE mode. This IDLE mode support is furnished by the IDLE timer T0, which is a 16-bit timer. The Timer T0 runs continuously at the fixed rate of the instruction cycle clock, t_c . The user cannot read or write to the IDLE Timer T0, which is a count down timer.

The Timer T0 supports the following functions:

- Exit out of the Idle Mode (See Idle Mode description)
- WATCHDOG logic (See WATCHDOG description)
- Start up delay out of the HALT mode

The IDLE Timer T0 can generate an interrupt when the thirteenth bit toggles. This toggle is latched into the T0PND pending flag, and will occur every 4 ms at the maximum clock frequency ($t_c = 1 \mu\text{s}$). A control flag T0EN allows the interrupt from the thirteenth bit of Timer T0 to be enabled or disabled. Setting T0EN will enable the interrupt, while resetting it will disable the interrupt.

TIMER T1 AND TIMER T2

The COP888CL has a set of two powerful timer/counter blocks, T1 and T2. The associated features and functioning of a timer block are described by referring to the timer block Tx. Since the two timer blocks, T1 and T2, are identical, all comments are equally applicable to either timer block.

Each timer block consists of a 16-bit timer, Tx, and two supporting 16-bit autoreload/capture registers, RxA and RxB. Each timer block has two pins associated with it, TxA and TxB. The pin TxA supports I/O required by the timer

block, while the pin TxB is an input to the timer block. The powerful and flexible timer block allows the COP888CL to easily perform all timer functions with minimal software overhead. The timer block has three operating modes: Processor Independent PWM mode, External Event Counter mode, and Input Capture mode.

The control bits Tx3, Tx2, and Tx1 allow selection of the different modes of operation.

Mode 1. Processor Independent PWM Mode

As the name suggests, this mode allows the COP888CL to generate a PWM signal with very minimal user intervention.

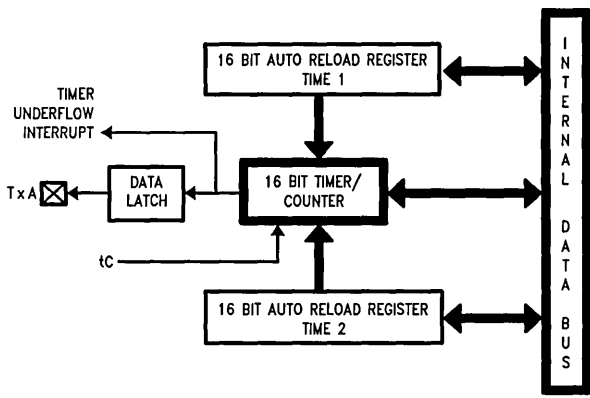

The user only has to define the parameters of the PWM signal (ON time and OFF time). Once begun, the timer block will continuously generate the PWM signal completely independent of the microcontroller. The user software services the timer block only when the PWM parameters require updating.

In this mode the timer Tx counts down at a fixed rate of t_c . Upon every underflow the timer is alternately reloaded with the contents of supporting registers, RxA and RxB. The very first underflow of the timer causes the timer to reload from the register RxA. Subsequent underflows cause the timer to be reloaded from the registers alternately beginning with the register RxB.

The Tx Timer control bits, Tx3, Tx2 and Tx1 set up the timer for PWM mode operation.

Figure 7 shows a block diagram of the timer in PWM mode.

Timers (Continued)

TL/DD/9766-13

FIGURE 7. Timer in PWM Mode

The underflows can be programmed to toggle the TxA output pin. The underflows can also be programmed to generate interrupts.

Underflows from the timer are alternately latched into two pending flags, TxPND A and TxPND B. The user must reset these pending flags under software control. Two control enable flags, TxENA and TxENB, allow the interrupts from the timer underflow to be enabled or disabled. Setting the timer enable flag TxENA will cause an interrupt when a timer underflow causes the RxA register to be reloaded into the timer. Setting the timer enable flag TxENB will cause an interrupt when a timer underflow causes the RxB register to be reloaded into the timer. Resetting the timer enable flags will disable the associated interrupts.

Either or both of the timer underflow interrupts may be enabled. This gives the user the flexibility of interrupting once per PWM period on either the rising or falling edge of the PWM output. Alternatively, the user may choose to interrupt on both edges of the PWM output.

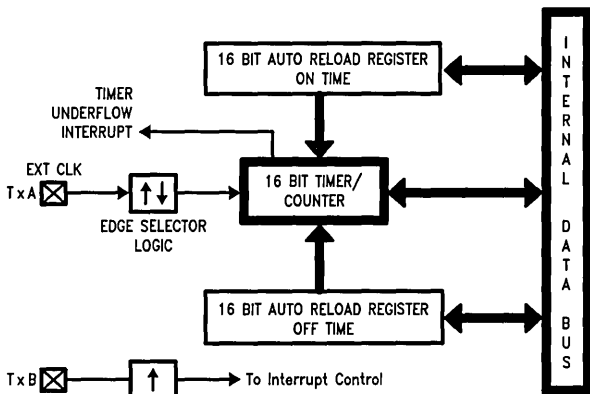

Mode 2. External Event Counter Mode

This mode is quite similar to the processor independent PWM mode described above. The main difference is that the timer, Tx, is clocked by the input signal from the TxA pin. The Tx timer control bits, Tx C3, Tx C2 and Tx C1 allow the timer to be clocked either on a positive or negative edge from the TxA pin. Underflows from the timer are latched into the TxPND A pending flag. Setting the TxENA control flag will cause an interrupt when the timer underflows.

In this mode the input pin Tx B can be used as an independent positive edge sensitive interrupt input if the TxENB control flag is set. The occurrence of a positive edge on the Tx B input pin is latched into the TxPND B flag.

Figure 8 shows a block diagram of the timer in External Event Counter mode.

Note: The PWM output is not available in this mode since the TxA pin is being used as the counter input clock.

TL/DD/9766-14

FIGURE 8. Timer in External Event Counter Mode

Timers (Continued)

Mode 3. Input Capture Mode

The COP888CL can precisely measure external frequencies or time external events by placing the timer block, Tx, in the input capture mode.

In this mode, the timer Tx is constantly running at the fixed t_c rate. The two registers, RxA and RxB, act as capture registers. Each register acts in conjunction with a pin. The register RxA acts in conjunction with the TxA pin and the register RxB acts in conjunction with the TxB pin.

The timer value gets copied over into the register when a trigger event occurs on its corresponding pin. Control bits, TxC3, TxC2 and TxC1, allow the trigger events to be specified either as a positive or a negative edge. The trigger condition for each input pin can be specified independently.

The trigger conditions can also be programmed to generate interrupts. The occurrence of the specified trigger condition on the TxA and TxB pins will be respectively latched into the pending flags, TxPNDA and TxPNDB. The control flag TxENA allows the interrupt on TxA to be either enabled or disabled. Setting the TxENA flag enables interrupts to be generated when the selected trigger condition occurs on the TxA pin. Similarly, the flag TxENB controls the interrupts from the TxB pin.

Underflows from the timer can also be programmed to generate interrupts. Underflows are latched into the timer TxCO pending flag (the TxCO control bit serves as the timer under-

flow interrupt pending flag in the Input Capture mode). Consequently, the TxCO control bit should be reset when entering the Input Capture mode. The timer underflow interrupt is enabled with the TxENA control flag. When a TxA interrupt occurs in the Input Capture mode, the user must check both the TxPNDA and TxCO pending flags in order to determine whether a TxA input capture or a timer underflow (or both) caused the interrupt.

Figure 9 shows a block diagram of the timer in Input Capture mode.

TIMER CONTROL FLAGS

The timers T1 and T2 have identical control structures. The control bits and their functions are summarized below.

TxCO	Timer Start/Stop control in Modes 1 and 2 (Processor Independent PWM and External Event Counter), where 1 = Start, 0 = Stop
	Timer Underflow Interrupt Pending Flag in Mode 3 (Input Capture)
TxPNDA	Timer Interrupt Pending Flag
TxPNDB	Timer Interrupt Pending Flag
TxENA	Timer Interrupt Enable Flag
TxENB	Timer Interrupt Enable Flag
	1 = Timer Interrupt Enabled
	0 = Timer Interrupt Disabled
TxC3	Timer mode control
TxC2	Timer mode control
TxC1	Timer mode control

FIGURE 9. Timer in Input Capture Mode

TL/DD/9766-15

Timers (Continued)

The timer mode control bits (TxC3, TxC2 and TxC1) are detailed below:

TxC3	TxC2	TxC1	Timer Mode	Interrupt A Source	Interrupt B Source	Timer Counts On
0	0	0	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Pos. Edge
0	0	1	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Neg. Edge
1	0	1	MODE 1 (PWM) TxA Toggle	Autoreload RA	Autoreload RB	t_c
1	0	0	MODE 1 (PWM) No TxA Toggle	Autoreload RA	Autoreload RB	t_c
0	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Pos. Edge	Pos. TxA Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Neg. Edge	Pos. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c
0	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Pos. Edge	Neg. TxB Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Neg. Edge	Neg. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c

Power Save Modes

The COP888CL offers the user two power save modes of operation: HALT and IDLE. In the HALT mode, all microcontroller activities are stopped. In the IDLE mode, the on-board oscillator circuitry and timer T0 are active but all other microcontroller activities are stopped. In either mode, all on-board RAM, registers, I/O states, and timers (with the exception of T0) are unaltered.

HALT MODE

The COP888CL is placed in the HALT mode by writing a "1" to the HALT flag (G7 data bit). All microcontroller activities, including the clock, timers, are stopped. The WATCHDOG logic on the COP888CL is disabled during the HALT mode. However, the clock monitor circuitry, if enabled, remains active and will cause the WATCHDOG output pin (WDOUT) to go low. If the HALT mode is used and the user does not want to activate the WDOUT pin, the Clock Monitor should be disabled after the device comes out of reset (resetting the Clock Monitor control bit with the first write to the WDSVR register). In the HALT mode, the power requirements of the COP888CL are minimal and the applied voltage (V_{CC}) may be decreased to V_r ($V_r = 2.0V$) without altering the state of the machine.

The COP888CL supports three different ways of exiting the HALT mode. The first method of exiting the HALT mode is

with the Multi-Input Wakeup feature on the L port. The second method is with a low to high transition on the CKO (G7) pin. This method precludes the use of the crystal clock configuration (since CKO becomes a dedicated output), and so may be used with an RC clock configuration. The third method of exiting the HALT mode is by pulling the \overline{RESET} pin low.

Since a crystal or ceramic resonator may be selected as the oscillator, the Wakeup signal is not allowed to start the chip running immediately since crystal oscillators and ceramic resonators have a delayed start up time to reach full amplitude and frequency stability. The IDLE timer is used to generate a fixed delay to ensure that the oscillator has indeed stabilized before allowing instruction execution. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry is enabled. The IDLE timer is loaded with a value of 256 and is clocked with the t_c instruction cycle clock. The t_c clock is derived by dividing the oscillator clock down by a factor of 10. The Schmitt trigger following the CKI inverter on the chip ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

Power Save Modes (Continued)

If an RC clock option is being used, the fixed delay is introduced optionally. A control bit, CLKDLY, mapped as configuration bit G7, controls whether the delay is to be introduced or not. The delay is included if CLKDLY is set, and excluded if CLKDLY is reset. The CLKDLY bit is cleared on reset.

The COP888CL has two mask options associated with the HALT mode. The first mask option enables the HALT mode feature, while the second mask option disables the HALT mode. With the HALT mode enable mask option, the COP888CL will enter and exit the HALT mode as described above. With the HALT disable mask option, the COP888CL cannot be placed in the HALT mode (writing a "1" to the HALT flag will have no effect).

The WATCHDOG detector circuit is inhibited during the HALT mode. However, the clock monitor circuit, if enabled, remains active during HALT mode in order to ensure a clock monitor error if the COP888CL inadvertently enters the HALT mode as a result of a runaway program or power glitch.

IDLE MODE

The COP888CL is placed in the IDLE mode by writing a "1" to the IDLE flag (G6 data bit). In this mode, all activity, except the associated on-board oscillator circuitry, the WATCHDOG logic, the clock monitor and the IDLE Timer T0, is stopped. The power supply requirements of the microcontroller in this mode of operation are typically around 30% of normal power requirement of the microcontroller.

As with the HALT mode, the COP888CL can be returned to normal operation with a reset, or with a Multi-Input Wake-up from the L Port. Alternately, the microcontroller resumes normal operation from the IDLE mode when the thirteenth bit (representing 4.096 ms at internal clock frequency of 1 MHz, $t_c = 1 \mu\text{s}$) of the IDLE Timer toggles.

This toggle condition of the thirteenth bit of the IDLE Timer T0 is latched into the TOPND pending flag.

The user has the option of being interrupted with a transition on the thirteenth bit of the IDLE Timer T0. The interrupt can be enabled or disabled via the T0EN control bit. Setting the T0EN flag enables the interrupt and vice versa.

The user can enter the IDLE mode with the Timer T0 interrupt enabled. In this case, when the TOPND bit gets set, the COP888CL will first execute the Timer T0 interrupt service routine and then return to the instruction following the "Enter Idle Mode" instruction.

Alternatively, the user can enter the IDLE mode with the IDLE Timer T0 interrupt disabled. In this case, the COP888CL will resume normal operation with the instruction immediately following the "Enter IDLE Mode" instruction.

Note: It is necessary to program two NOP instructions following both the set HALT mode and set IDLE mode instructions. These NOP instructions are necessary to allow clock resynchronization following the HALT or IDLE modes.

Multi-Input Wakeup

The Multi-Input Wakeup feature is used to return (wakeup) the COP888CL from either the HALT or IDLE modes. Alternately Multi-Input Wakeup/Interrupt feature may also be used to generate up to 8 edge selectable external interrupts.

Figure 10 shows the Multi-Input Wakeup logic for the COP888CL microcontroller.

The Multi-Input Wakeup feature utilizes the L Port. The user selects which particular L port bit (or combination of L Port bits) will cause the COP888CL to exit the HALT or IDLE modes. The selection is done through the Reg: WKEN. The Reg: WKEN is an 8-bit read/write register, which contains a control bit for every L port bit. Setting a particular WKEN bit enables a Wakeup from the associated L port pin.

The user can select whether the trigger condition on the selected L Port pin is going to be either a positive edge (low to high transition) or a negative edge (high to low transition). This selection is made via the Reg: WKEDG, which is an 8-bit control register with a bit assigned to each L Port pin. Setting the control bit will select the trigger condition to be a negative edge on that particular L Port pin. Resetting the bit selects the trigger condition to be a positive edge. Changing an edge select entails several steps in order to avoid a pseudo Wakeup condition as a result of the edge change. First, the associated WKEN bit should be reset, followed by the edge select change in WKEDG. Next, the associated WKPND bit should be cleared, followed by the associated WKEN bit being re-enabled.

An example may serve to clarify this procedure. Suppose we wish to change the edge select from positive (low going high) to negative (high going low) for L Port bit 5, where bit 5 has previously been enabled for an input interrupt. The program would be as follows:

```

RBIT 5, WKEN
SBIT 5, WKEDG
RBIT 5, WKPND
SBIT 5, WKEN
  
```

If the L port bits have been used as outputs and then changed to inputs with Multi-Input Wakeup/Interrupt, a safety procedure should also be followed to avoid inherited pseudo wakeup conditions. After the selected L port bits have been changed from output to input but before the associated WKEN bits are enabled, the associated edge select bits in WKEDG should be set or reset for the desired edge selects, followed by the associated WKPND bits being cleared.

This same procedure should be used following reset, since the L port inputs are left floating as a result of reset.

The occurrence of the selected trigger condition for Multi-Input Wakeup is latched into a pending register called WKPND. The respective bits of the WKPND register will be set on the occurrence of the selected trigger edge on the corresponding Port L pin. The user has the responsibility of clearing these pending flags. Since WKPND is a pending register for the occurrence of selected wakeup conditions, the COP888CL will not enter the HALT mode if any Wakeup bit is both enabled and pending. Consequently, the user has the responsibility of clearing the pending flags before attempting to enter the HALT mode.

The WKEN, WKPND and WKEDG are all read/write registers, and are cleared at reset.

PORT L INTERRUPTS

Port L provides the user with an additional eight fully selectable, edge sensitive interrupts which are all vectored into the same service subroutine.

The interrupt from Port L shares logic with the wake up circuitry. The register WKEN allows interrupts from Port L to

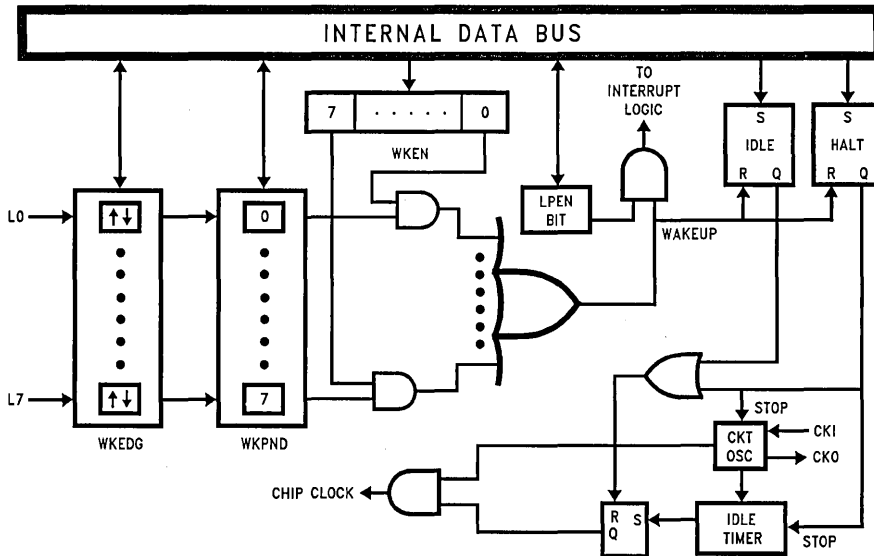

FIGURE 10. Multi-Input Wake Up Logic

TL/DD/9766-16

Multi-Input Wakeup (Continued)

be individually enabled or disabled. The register WKEDG specifies the trigger condition to be either a positive or a negative edge. Finally, the register WKPND latches in the pending trigger conditions.

The GIE (Global Interrupt Enable) bit enables the interrupt function.

A control flag, LPEN, functions as a global interrupt enable for Port L interrupts. Setting the LPEN flag will enable interrupts and vice versa. A separate global pending flag is not needed since the register WKPND is adequate.

Since Port L is also used for waking the COP888CL out of the HALT or IDLE modes, the user can elect to exit the HALT or IDLE modes either with or without the interrupt enabled. If he elects to disable the interrupt, then the COP888CL will restart execution from the instruction immediately following the instruction that placed the microcontroller in the HALT or IDLE modes. In the other case, the COP888CL will first execute the interrupt service routine and then revert to normal operation.

The Wakeup signal will not start the chip running immediately since crystal oscillators or ceramic resonators have a finite start up time. The IDLE Timer (T0) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the COP888CL to execute instructions. In this

case, upon detecting a valid Wakeup signal, only the oscillator circuitry and the IDLE Timer T0 are enabled. The IDLE Timer is loaded with a value of 256 and is clocked from the t_c instruction cycle clock. The t_c clock is derived by dividing down the oscillator clock by a factor of 10. A Schmitt trigger following the CKI on-chip inverter ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If the RC clock option is used, the fixed delay is under software control. A control flag, CLKDLY, in the G7 configuration bit allows the clock start up delay to be optionally inserted. Setting CLKDLY flag high will cause clock start up delay to be inserted and resetting it will exclude the clock start up delay. The CLKDLY flag is cleared during reset, so the clock start up delay is not present following reset with the RC clock options.

Interrupts

The COP888CL supports a vectored interrupt scheme. It supports a total of ten interrupt sources. The following table lists all the possible COP888CL interrupt sources, their arbitration ranking and the memory locations reserved for the interrupt vector for each source.

Arbitration Ranking	Source	Description	Vector Address Hi-Low Byte
(1) Highest	Software	INTR Instruction	0yFE-0yFF
	Reserved	for Future Use	0yFC-0yFD
(2)	External	Pin G0 Edge	0yFA-0yFB
(3)	Timer T0	Underflow	0yF8-0yF9
(4)	Timer T1	T1A/Underflow	0yF6-0yF7
(5)	Timer T1	T1B	0yF4-0yF5
	MICROWIRE/PLUS	BUSY Goes Low	0yF2-0yF3
	Reserved	for Future Use	0yF0-0yF1
	Reserved	for UART	0yEE-0yEF
(6)	Reserved	for UART	0yEC-0yED
	Timer T2	T2A/Underflow	0yEA-0yEB
	Timer T2	T2B	0yE8-0yE9
	Reserved	for Future Use	0yE6-0yE7
(7)	Reserved	for Future Use	0yE4-0yE5
	Port L/Wakeup	Port L Edge	0yE2-0yE3
	(9)	Default	VIS Instr. Execution without Any Interrupts
(10) Lowest			

y is VIS page, y ≠ 0.

Interrupts (Continued)

Two bytes of program memory space are reserved for each interrupt source. All interrupt sources except the software interrupt are maskable. Each of the maskable interrupts have an Enable bit and a Pending bit. A maskable interrupt is active if its associated enable and pending bits are set. If $GIE = 1$ and an interrupt is active, then the processor will be interrupted as soon as it is ready to start executing an instruction except if the above conditions happen during the Software Trap service routine. This exception is described in the Software Trap sub-section.

The interruption process is accomplished with the INTR instruction (opcode 00), which is jammed inside the Instruction Register and replaces the opcode about to be executed. The following steps are performed for every interrupt:

1. The GIE (Global Interrupt Enable) bit is reset.
2. The address of the instruction about to be executed is pushed into the stack.
3. The PC (Program Counter) branches to address 00FF. This procedure takes $7 t_c$ cycles to execute.

At this time, since $GIE = 0$, other maskable interrupts are disabled. The user is now free to do whatever context switching is required by saving the context of the machine in the stack with PUSH instructions. The user would then program a VIS (Vector Interrupt Select) instruction in order to branch to the interrupt service routine of the highest priority interrupt enabled and pending at the time of the VIS. Note that this is not necessarily the interrupt that caused the branch to address location 00FF Hex prior to the context switching.

Thus, if an interrupt with a higher rank than the one which caused the interruption becomes active before the decision of which interrupt to service is made by the VIS, then the interrupt with the higher rank will override any lower ones and will be acknowledged. The lower priority interrupt(s) are still pending, however, and will cause another interrupt immediately following the completion of the interrupt service

routine associated with the higher priority interrupt just serviced. This lower priority interrupt will occur immediately following the RETI (Return from Interrupt) instruction at the end of the interrupt service routine just completed.

Inside the interrupt service routine, the associated pending bit has to be cleared by software. The RETI (Return from Interrupt) instruction at the end of the interrupt service routine will set the GIE (Global Interrupt Enable) bit, allowing the processor to be interrupted again if another interrupt is active and pending.

The VIS instruction looks at all the active interrupts at the time it is executed and performs an indirect jump to the beginning of the service routine of the one with the highest rank.

The addresses of the different interrupt service routines, called vectors, are chosen by the user and stored in ROM in a table starting at 01E0 (assuming that VIS is located between 00FF and 01DF). The vectors are 15-bit wide and therefore occupy 2 ROM locations.

VIS and the vector table must be located in the same 256-byte block (0y00 to 0yFF) except if VIS is located at the last address of a block. In this case, the table must be in the next block. The vector table cannot be inserted in the first 256-byte block.

The vector of the maskable interrupt with the lowest rank is located at 0yE0 (Hi-Order byte) and 0yE1 (Lo-Order byte) and so forth in increasing rank number. The vector of the maskable interrupt with the highest rank is located at 0yFA (Hi-Order byte) and 0yFB (Lo-Order byte).

The Software Trap has the highest rank and its vector is located at 0yFE and 0yFF.

If, by accident, a VIS gets executed and no interrupt is active, then the PC (Program Counter) will branch to a vector located at 0yE0-0yE1. This vector can point to the Software Trap (ST) interrupt service routine, or to another special service routine as desired.

Figure 11 shows the COP888CL Interrupt block diagram.

FIGURE 11. COP888CL Interrupt Block Diagram

TL/DD/9766-18

Interrupts (Continued)

SOFTWARE TRAP

The Software Trap (ST) is a special kind of non-maskable interrupt which occurs when the INTR instruction (used to acknowledge interrupts) is fetched from ROM and placed inside the instruction register. This may happen when the PC is pointing beyond the available ROM address space or when the stack is over-popped.

When an ST occurs, the user can re-initialize the stack pointer and do a recovery procedure (similar to reset, but not necessarily containing all of the same initialization procedures) before restarting.

The occurrence of an ST is latched into the ST pending bit. The GIE bit is not affected and the ST pending bit (**not accessible by the user**) is used to inhibit other interrupts and to direct the program to the ST service routine with the VIS instruction. The RPND instruction is used to clear the software interrupt pending bit. This pending bit is also cleared on reset.

The ST has the highest rank among all interrupts.

Nothing (except another ST) can interrupt an ST being serviced.

WATCHDOG

The COP888CL contains a WATCHDOG and clock monitor. The WATCHDOG is designed to detect the user program getting stuck in infinite loops resulting in loss of program control or "runaway" programs. The Clock Monitor is used to detect the absence of a clock or a very slow clock below a specified rate on the CKI pin.

The WATCHDOG consists of two independent logic blocks: WD UPPER and WD LOWER. WD UPPER establishes the upper limit on the service window and WD LOWER defines the lower limit of the service window.

Servicing the WATCHDOG consists of writing a specific value to a WATCHDOG Service Register named WDSVR which is memory mapped in the RAM. This value is composed of three fields, consisting of a 2-bit Window Select, a 5-bit Key Data field, and the 1-bit Clock Monitor Select field. Table I shows the WDSVR register.

The lower limit of the service window is fixed at 2048 instruction cycles. Bits 7 and 6 of the WDSVR register allow the user to pick an upper limit of the service window.

Table II shows the four possible combinations of lower and upper limits for the WATCHDOG service window. This flexibility in choosing the WATCHDOG service window prevents any undue burden on the user software.

Bits 5, 4, 3, 2 and 1 of the WDSVR register represent the 5-bit Key Data field. The key data is fixed at 01100. Bit 0 of the WDSVR Register is the Clock Monitor Select bit.

TABLE I. WATCHDOG Service Register (WDSVR)

Window Select		Key Data					Clock Monitor
X	X	0	1	1	0	0	Y
7	6	5	4	3	2	1	0

TABLE II. WATCHDOG Service Window Select

WDSVR Bit 7	WDSVR Bit 6	Service Window (Lower-Upper Limits)
0	0	2k-8k t_c Cycles
0	1	2k-16k t_c Cycles
1	0	2k-32k t_c Cycles
1	1	2k-64k t_c Cycles

Clock Monitor

The Clock Monitor aboard the COP888CL can be selected or deselected under program control. The Clock Monitor is guaranteed not to reject the clock if the instruction cycle clock ($1/t_c$) is greater or equal to 10 kHz. This equates to a clock input rate on CKI of greater or equal to 100 kHz.

WATCHDOG Operation

The WATCHDOG and Clock Monitor are disabled during reset. The COP888CL comes out of reset with the WATCHDOG armed, the WATCHDOG Window Select bits (bits 6, 7 of the WDSVR Register) set, and the Clock Monitor bit (bit 0 of the WDSVR Register) enabled. Thus, a Clock Monitor error will occur after coming out of reset, if the instruction cycle clock frequency has not reached a minimum specified value, including the case where the oscillator fails to start.

The WDSVR register can be written to only once after reset and the key data (bits 5 through 1 of the WDSVR Register) must match to be a valid write. This write to the WDSVR register involves two irrevocable choices: (i) the selection of the WATCHDOG service window (ii) enabling or disabling of the Clock Monitor. Hence, the first write to WDSVR Register involves selecting or deselecting the Clock Monitor, select the WATCHDOG service window and match the WATCHDOG key data. Subsequent writes to the WDSVR register will compare the value being written by the user to the WATCHDOG service window value and the key data (bits 7 through 1) in the WDSVR Register. Table III shows the sequence of events that can occur.

The user must service the WATCHDOG at least once before the upper limit of the service window expires. The WATCHDOG may not be serviced more than once in every lower limit of the service window. The user may service the WATCHDOG as many times as wished in the time period between the lower and upper limits of the service window. The first write to the WDSVR Register is also counted as a WATCHDOG service.

The WATCHDOG has an output pin associated with it. This is the WDOUT pin, on pin 1 of the port G. WDOUT is active low. The WDOUT pin is in the high impedance state in the inactive state. Upon triggering the WATCHDOG, the logic will pull the WDOUT (G1) pin low for an additional $16 t_c$ – $32 t_c$ cycles after the signal level on WDOUT pin goes below the lower Schmitt trigger threshold. After this delay, the COP888CL will stop forcing the WDOUT output low.

The WATCHDOG service window will restart when the WDOUT pin goes high. It is recommended that the user tie the WDOUT pin back to V_{CC} through a resistor in order to pull WDOUT high.

A WATCHDOG service while the WDOUT signal is active will be ignored. The state of the WDOUT pin is not guaranteed on reset, but if it powers up low then the WATCHDOG will time out and WDOUT will enter high impedance state.

WATCHDOG Operation (Continued)**TABLE III. WATCHDOG Service Actions**

Key Data	Window Data	Clock Monitor	Action
Match	Match	Match	Valid Service: Restart Service Window
Don't Care	Mismatch	Don't Care	Error: Generate WATCHDOG Output
Mismatch	Don't Care	Don't Care	Error: Generate WATCHDOG Output
Don't Care	Don't Care	Mismatch	Error: Generate WATCHDOG Output

**TABLE IV. MICROWIRE/PLUS
Master Mode Clock Select**

SL1	SL0	SK
0	0	$2 \times t_c$
0	1	$4 \times t_c$
1	x	$8 \times t_c$

Where t_c is the instruction cycle clock

The Clock Monitor forces the G1 pin low upon detecting a clock frequency error. The Clock Monitor error will continue until the clock frequency has reached the minimum specified value, after which the G1 output will enter the high impedance TRI-STATE mode following $16 t_c$ – $32 t_c$ clock cycles. The Clock Monitor generates a continual Clock Monitor error if the oscillator fails to start, or fails to reach the minimum specified frequency. The specification for the Clock Monitor is as follows:

$1/t_c > 10$ kHz—No clock rejection.

$1/t_c < 10$ Hz—Guaranteed clock rejection.

WATCHDOG AND CLOCK MONITOR SUMMARY

The following salient points regarding the COP888 WATCHDOG and Clock Monitor should be noted:

- Both WATCHDOG and Clock Monitor detector circuits are inhibited during reset.
- Following reset, the WATCHDOG and Clock Monitor are both enabled, with the WATCHDOG having the maximum service window selected.
- The WATCHDOG service window and Clock Monitor enable/disable option can only be changed once, during the initial WATCHDOG service following reset.
- The initial WATCHDOG service must match the key data value in the WATCHDOG Service register WDSVR in order to avoid a WATCHDOG error.
- Subsequent WATCHDOG services must match all three data fields in WDSVR in order to avoid WATCHDOG errors.
- The correct key data value cannot be read from the WATCHDOG Service register WDSVR. Any attempt to read this key data value of 01100 from WDSVR will read as key data value of all 0's.
- The WATCHDOG detector circuit is inhibited during both the HALT and IDLE modes.
- The Clock Monitor detector circuit is active during both the HALT and IDLE modes. Consequently, the COP888 inadvertently entering the HALT mode will be detected as a Clock Monitor error (provided that the Clock Monitor enable option has been selected by the program).

- With the single-pin R/C oscillator mask option selected and the CLKDLY bit reset, the WATCHDOG service window will resume following HALT mode from where it left off before entering the HALT mode.
- With the crystal oscillator mask option selected, or with the single-pin R/C oscillator mask option selected and the CLKDLY bit set, the WATCHDOG service window will be set to its selected value from WDSVR following HALT. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following HALT, but must be serviced within the selected window to avoid a WATCHDOG error.
- The IDLE timer T0 is not initialized with reset.
- The user can sync in to the IDLE counter cycle with an IDLE counter (T0) interrupt or by monitoring the TOPND flag. The TOPND flag is set whenever the thirteenth bit of the IDLE counter toggles (every 4096 instruction cycles). The user is responsible for resetting the TOPND flag.
- A hardware WATCHDOG service occurs just as the COP888 exits the IDLE mode. Consequently, the Watchdog should not be serviced for at least 2048 instruction cycles following IDLE, but must be serviced within the selected window to avoid a WATCHDOG error.
- Following reset, the initial WATCHDOG service (where the service window and the Clock Monitor enable/disable must be selected) may be programmed anywhere within the maximum service window (65,536 instruction cycles) initialized by RESET. Note that this initial WATCHDOG service may be programmed within the initial 2048 instruction cycles without causing a WATCHDOG error.

Detection of Illegal Conditions

The COP888CL can detect various illegal conditions resulting from coding errors, transient noise, power supply voltage drops, runaway programs, etc.

Reading of undefined ROM gets zeros. The opcode for software interrupt is zero. If the program fetches instructions from undefined ROM, this will force a software interrupt, thus signaling that an illegal condition has occurred.

Detection of Illegal Conditions (Continued)

The subroutine stack grows down for each call (jump to subroutine), interrupt, or PUSH, and grows up for each return or POP. The stack pointer is initialized to RAM location 06F Hex during reset. Consequently, if there are more returns than calls, the stack pointer will point to addresses 070 and 071 Hex (which are undefined RAM). Undefined RAM from addresses 070 to 07F Hex is read as all 1's, which in turn will cause the program to return to address 7FFF Hex. This is an undefined ROM location and the instruction fetched (all 0's) from this location will generate a software interrupt signaling an illegal condition.

Thus, the chip can detect the following illegal conditions:

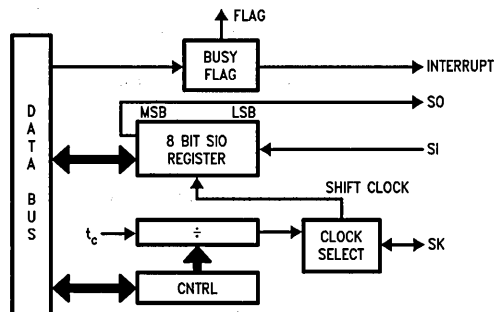

- Executing from undefined ROM
- Over "POP"ing the stack by having more returns than calls.

When the software interrupt occurs, the user can re-initialize the stack pointer and do a recovery procedure before re-starting (this recovery program is probably similar to that following reset, but might not contain the same program initialization procedures). The recovery program should reset the software interrupt pending bit using the RPND instruction.

MICROWIRE/PLUS

MICROWIRE/PLUS is a serial synchronous communications interface. The MICROWIRE/PLUS capability enables the COP888CL to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, E²PROMs etc.) and with other microcontrollers which support the MICROWIRE interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). *Figure 12* shows a block diagram of the MICROWIRE logic.

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS arrangement with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE arrangement with an external shift clock is called the Slave mode of operation.

TL/DD/9766-20

FIGURE 12. MICROWIRE/PLUS Block Diagram

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. In the

master mode, the SK clock rate is selected by the two bits, SL0 and SL1, in the CNTRL register. Table IV details the different clock rates that may be selected.

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. If enabled, an interrupt is generated when eight data bits have been shifted. The COP888CL may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. *Figure 13* shows how two COP888CL microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangements.

Warning:

The SIO register should only be loaded when the SK clock is low. Loading the SIO register while the SK clock is high will result in undefined data in the SIO register. The SK clock is normally low when not shifting.

Setting the BUSY flag when the input SK clock is high in the MICROWIRE/PLUS slave mode may cause the current SK clock for the SIO shift register to be narrow. For safety, the BUSY flag should only be set when the input SK clock is low.

MICROWIRE/PLUS Master Mode Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the COP888CL. The MICROWIRE Master always initiates all data exchanges. The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table V summarizes the bit settings required for Master mode of operation.

MICROWIRE/PLUS Slave Mode Operation

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by setting and resetting the appropriate bit in the Port G configuration register. Table V summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated.

Alternate SK Phase Operation

The COP888CL allows either the normal SK clock or an alternate phase SK clock to shift data in and out of the SIO register. In both the modes the SK is normally low. In the normal mode data is shifted in on the rising edge of the SK clock and the data is shifted out on the falling edge of the SK clock. The SIO register is shifted on each falling edge of the SK clock. In the alternate SK phase operation, data is shifted in on the falling edge of the SK clock and shifted out on the rising edge of the SK clock.

MICROWIRE/PLUS (Continued)

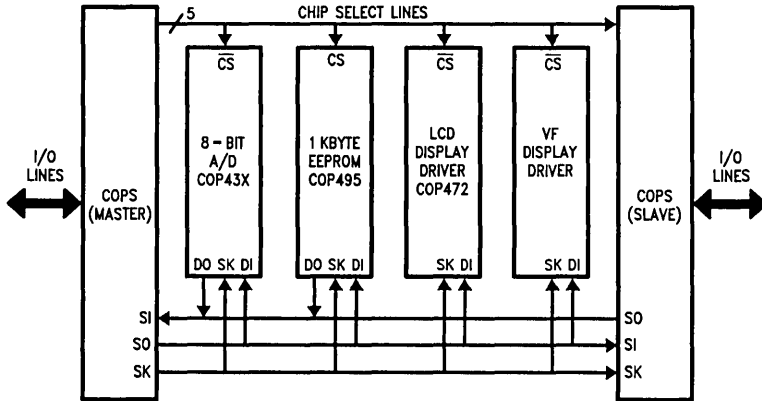

FIGURE 13. MICROWIRE/PLUS Application

TL/DD/9766-21

A control flag, SKSEL, allows either the normal SK clock or the alternate SK clock to be selected. Resetting SKSEL causes the MICROWIRE/PLUS logic to be clocked from the normal SK signal. Setting the SKSEL flag selects the alternate SK clock. The SKSEL is mapped into the G6 configuration bit. The SKSEL flag will power up in the reset condition, selecting the normal SK signal.

TABLE V

This table assumes that the control flag MSEL is set.

G4 (SO) Config. Bit	G5 (SK) Config. Bit	G4 Fun.	G5 Fun.	Operation
1	1	SO	Int. SK	MICROWIRE/PLUS Master
0	1	TRI-STATE	Int. SK	MICROWIRE/PLUS Master
1	0	SO	Ext. SK	MICROWIRE/PLUS Slave
0	0	TRI-STATE	Ext. SK	MICROWIRE/PLUS Slave

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space

Address	Contents

F0 to FB	On-Chip RAM Mapped as Registers
FC	X Register
FD	SP Register
FE	B Register
FF	Reserved

Reading memory locations 70-7F Hex will return all ones. Reading other unused memory locations will return undefined data.

Addressing Modes

The COP888CL has ten addressing modes, six for operand addressing and four for transfer of control.

OPERAND ADDRESSING MODES

Register Indirect

This is the "normal" addressing mode for the COP888CL. The operand is the data memory addressed by the B pointer or X pointer.

Register Indirect (with auto post increment or decrement of pointer)

This addressing mode is used with the LD and X instructions. The operand is the data memory addressed by the B pointer or X pointer. This is a register indirect mode that automatically post increments or decrements the B or X register after executing the instruction.

Direct

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

Immediate

The instruction contains an 8-bit immediate field as the operand.

Short Immediate

This addressing mode is used with the Load B Immediate instruction. The instruction contains a 4-bit immediate field as the operand.

Indirect

This addressing mode is used with the LAID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a data operand from the program memory.

TRANSFER OF CONTROL ADDRESSING MODES

Relative

This mode is used for the JP instruction, with the instruction field being added to the program counter to get the new program location. JP has a range from -31 to +32 to allow a 1-byte relative jump (JP + 1 is implemented by a NOP instruction). There are no "pages" when using JP, since all 15 bits of PC are used.

Absolute

This mode is used with the JMP and JSR instructions, with the instruction field of 12 bits replacing the lower 12 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory segment.

Absolute Long

This mode is used with the JMPL and JSRL instructions, with the instruction field of 15 bits replacing the entire 15 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory space.

Indirect

This mode is used with the JID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a location in the program memory. The contents of this program memory location serve as a partial address (lower 8 bits of PC) for the jump to the next instruction.

Note: The VIS is a special case of the Indirect Transfer of Control addressing mode, where the double byte vector associated with the interrupt is transferred from adjacent addresses in the program memory into the program counter (PC) in order to jump to the associated interrupt service routine.

Instruction Set

Register and Symbol Definition

Registers	
A	8-Bit Accumulator Register
B	8-Bit Address Register
X	8-Bit Address Register
SP	8-Bit Stack Pointer Register
PC	15-Bit Program Counter Register
PU	Upper 7 Bits of PC
PL	Lower 8 Bits of PC
C	1 Bit of PSW Register for Carry
HC	1 Bit of PSW Register for Half Carry
GIE	1 Bit of PSW Register for Global Interrupt Enable
VU	Interrupt Vector Upper Byte
VL	Interrupt Vector Lower Byte

Symbols	
[B]	Memory Indirectly Addressed by B Register

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instructions taking two bytes).

Most single byte instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

Bytes and Cycles per Instruction

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

Where,

i is the immediate data

Md is a directly addressed memory location

* is an unused opcode

Note: The opcode 60 Hex is also the opcode for IFBIT #i,A

Mask Options

The COP888CL mask programmable options are shown below. The options are programmed at the same time as the ROM pattern submission.

OPTION 1: CLOCK CONFIGURATION

- = 1 Crystal Oscillator (CKI/10)
G7 (CK0) is clock generator output to crystal/resonator
CKI is the clock input
- = 2 Single-pin RC controlled oscillator (CKI/10)
G7 is available as a HALT restart and/or general purpose input

OPTION 2: HALT

- = 1 Enable HALT mode
- = 2 Disable HALT mode

OPTION 3: COP888CL BONDING

- = 1 44-Pin PCC
- = 2 40-Pin DIP
- = 3 N.A.
- = 4 28-Pin DIP
- = 5 28-Pin SO

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (if clock option-1 has been selected). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real-time, full-speed emulation, up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user-selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time

spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bar graph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC® via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS 232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MHW-884CL28D5PC	28 DIP	4.5V-5.5V	COP884CL
MHW-884CL28DWPC	28 DIP	2.5V-6.0V	COP884CL
MHW-888CL40D5PC	40 DIP	4.5V-5.5V	COP888CL
MHW-888CL40DWPC	40 DIP	2.5V-6.0V	COP888CL
MHW-888CL44D5PC	44 PLCC	4.5V-5.5V	COP888CL
MHW-888CL44DWPC	44 PLCC	2.5V-6.0V	COP888CL

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

MOLE-COP8-IBM	COP8 macro cross assembler for IBM® PC-XT®, PC-AT® or compatible	424410527-001

Development Support (Continued)

SIMULATOR

The COP8 Designer's Tool Kit is available for evaluating National Semiconductor's COP8 microcontroller family. The kit contains programmer's manuals, device datasheets, pocket reference guide, assembler and simulator, which allows the user to write, test, debug and run code on an industry standard compatible PC. The simulator has a windowed user interface and can handle script files that simulate hardware inputs, interrupts and automatic command processing. The capture file feature enables the user to record to a file current cycle and output port changes which are caused by the program under test.

Simulator Ordering Information

Part Number	Description	Manual
COP8-TOOL-KIT	COP8 Designer's Tool Kit Assembler and Simulator	420420270-001 424420269-001

SINGLE-CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

PROGRAM SUPPORT

Programming of the single-chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single-chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 FAX: (206) 882-104

Duplicate Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator Board for 28 DIP Multi-Chip Module (MCM) and for use with Scrambler Boards	COP884CLMHD
COP8-SCRM-DIP	MCM Scrambler Board for 40 DIP Socket	COP888CLMHD
COP8-SCRM-PCC	MCM Scrambler Board for 44 PLCC/LDCC	COP888CLMHEL
COP8-SCRM-SBX	MCM Scrambler Board for 28 LCC Socket	COP884CLMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler Board	COP884CLMHD, COP888CLMHD
COP8-PRGM-PCC	Duplicator Board with COP8-SCRM-PCC Scrambler Board	COP888CLMEL, COP884CLMHD

Single-Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates

COP884CLMHD-X	X = 1: crystal X = 3: R/C	28 DIP	MCM, UV Erasable	COP884CL
COP884CLMHEA-X	X = 1: crystal X = 3: R/C	28 LCC	MCM (same footprint as 28 SO), UV Erasable	COP884CL

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information System.

Information System

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

Voice: (408) 721-5582
Modem: (408) 739-1162
Baud: 300 or 1200 baud
Set-up: Length: 8-Bit
Parity: None
Stop Bit 1
Operation: 24 Hours, 7 Days

Order P/N: MOLE-DIAL-A-HLP

Information System Package Contents
Dial-A-Helper User Manual P/N
Public Domain Communications Software

Factory Applications Support

Dial-A-Helper also provides immediate factor applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

COP988CF/COP984CF/COP888CF/COP884CF

Single-Chip microCMOS Microcontroller

General Description

The COP888 family of microcontrollers uses an 8-bit single chip core architecture fabricated with National Semiconductor's M²CMOS™ process technology. The COP888CF is a member of this expandable 8-bit core processor family of microcontrollers.

(Continued)

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μ s instruction cycle time
- 4096 bytes on-board ROM
- 128 bytes on-board RAM
- Single supply operation: 2.5V–6V
- 8-channel A/D converter with prescaler and both differential and single ended modes
- MICROWIRE/PLUSTM serial I/O
- WATCHDOG™ and Clock Monitor logic
- Ten multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Two Timers (Each with 2 Interrupts)
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - Default VIS
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- Two 16-bit timers, each with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Versatile instruction set
- True bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 PLCC or 40 N
 - 44 PLCC with 37 I/O pins
 - 40 N with 33 I/O pins
 - 28 SO or 28 N, each with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Temperature ranges: –40°C to + 85°C
–55°C to + 125°C
- Emulation device—COP888CFMH
- Real time emulation and full program debug offered by National's Development Systems

Block Diagram

FIGURE 1. COP888CF Block Diagram

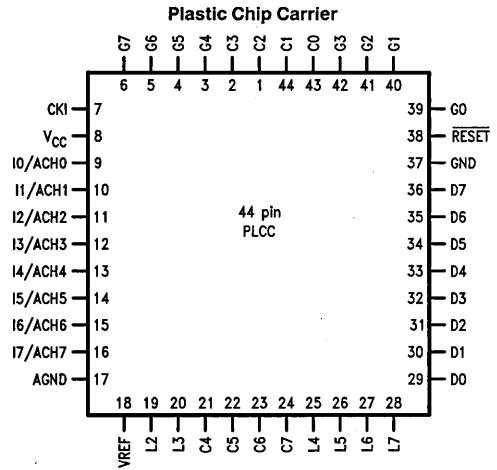

TL/DD/9425-1

General Description (Continued)

It is a fully static part, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS serial I/O, two 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), an 8-channel, 8-bit A/D converter with both differential and single ended modes, and two power savings modes (HALT and

IDLE), both with a multi-sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The COP888CF operates over a voltage range of 2.5V to 6V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

Note 1: Rate of voltage change must be less than 0.5 V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L and G ports in the TRI-STATE mode and tied to ground, all outputs low and tied to ground. The A/D is disabled. V_{REF} is tied to AGND (effectively shorting the Reference resistor). The clock monitor is disabled.

DC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$ unless otherwise specified (Continued)

Parameter	Conditions	Min	Typ	Max	Units
TRI-STATE Leakage	$V_{CC} = 6.0\text{V}$	-1		+1	μA
Allowable Sink/Source Current per Pin					
D Outputs (Sink)				15	mA
All others				3	mA

Input Capacitance				7	pF
Load Capacitance on D2				1000	pF

A/D Converter Specifications $V_{CC} = 5\text{V} \pm 10\% (V_{SS} - 0.050\text{V}) \leq \text{Any Input} \leq (V_{CC} + 0.050\text{V})$

Parameter	Conditions	Min	Typ	Max	Units
Resolution				8	Bits
Reference Voltage Input	AGND = 0V	3		V_{CC}	V
Absolute Accuracy	$V_{REF} = V_{CC}$			± 1	LSB
Non-Linearity	$V_{REF} = V_{CC}$ Deviation from the Best Straight Line			$\pm 1/2$	LSB
Differential Non-Linearity	$V_{REF} = V_{CC}$			$\pm 1/2$	LSB
Input Reference Resistance		1.6		4.8	$k\Omega$
Common Mode Input Range (Note 7)		AGND		V_{REF}	V
DC Common Mode Error				$\pm 1/4$	LSB
Off Channel Leakage Current			1		μA
On Channel Leakage Current			1		μA
A/D Clock Frequency (Note 5)		0.1		1.67	MHz
Conversion Time (Note 4)			12		A/D Clock Cycles

Note 4: Conversion Time includes sample and hold time.

Note 5: See Prescaler description.

Note 6: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

Note 7: For $V_{IN(-)} \geq V_{IN(+)}$ the digital output code will be 0000 0000. Two on-chip diodes are tied to each analog input. The diodes will forward conduct for analog input voltages below ground or above the V_{CC} supply. Be careful, during testing at low V_{CC} levels (4.5V), as high level analog inputs (5V) can cause this input diode to conduct—especially at elevated temperatures, and cause errors for analog inputs near full-scale. The spec allows 50 mV forward bias of either diode. This means that as long as the analog V_{IN} does not exceed the supply voltage by more than 50 mV, the output code will be correct. To achieve an absolute 0 V_{DC} to 5 V_{DC} input voltage range will therefore require a minimum supply voltage of 4.950 V_{DC} over temperature variations, initial tolerance and loading.

AC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$ unless otherwise specified

	$V_{CC} = 2.5V, V_{OH} = 1.8V$	0.2			mA
Sink (Push-Pull Mode)	$V_{CC} = 4V, V_{OL} = 0.4V$	1.6			mA
	$V_{CC} = 2.5V, V_{OL} = 0.4V$	0.7			mA
TRI-STATE Leakage	$V_{CC} = 6.0V$	-2		+2	μA

Note 1: Rate of voltage change must be less than 0.5 V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L and G ports in the TRI-STATE mode and tied to ground, all outputs low and tied to ground. The A/D is disabled. V_{REF} is tied to AGND (effectively shorting the Reference resistor). The clock monitor is disabled.

DC Electrical Characteristics 888CF: $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ unless otherwise specified (Continued)

Conversion Time (Note 4)			12		A/D Clock Cycles

Note 4: Conversion Time includes sample and hold time.**Note 5:** See Prescaler description.**Note 6:** Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.**Note 7:** For $V_{IN(-)} \geq V_{IN(+)}$ the digital output code will be 0000 0000. Two on-chip diodes are tied to each analog input. The diodes will forward conduct for analog input voltages below ground or above the V_{CC} supply. Be careful, during testing at low V_{CC} levels (4.5V), as high level analog inputs (5V) can cause this input diode to conduct—especially at elevated temperatures, and cause errors for analog inputs near full-scale. The spec allows 50 mV forward bias of either diode. This means that as long as the analog V_{IN} does not exceed the supply voltage by more than 50 mV, the output code will be correct. To achieve an absolute 0 V_{DC} to 5 V_{DC} input voltage range will therefore require a minimum supply voltage of 4.950 V_{DC} over temperature variations, initial tolerance and loading.

FIGURE 3. MICROWIRE/PLUS Timing

TL/DD/9425-26

Typical Performance Characteristics

Pin Descriptions

V_{CC} and GND are the power supply pins.

V_{REF} and AGND are the reference voltage pins for the on-board A/D converter.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

\overline{RESET} is the master reset input. See Reset Description section.

The COP888CF contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input (Schmitt trigger inputs on ports G and L), output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. (See the COP888CF memory map for the various addresses associated with the I/O ports.) Figure 4 shows the I/O port configurations for the COP888CF. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

TL/DD/9425-6

FIGURE 4. I/O Port Configurations

PORT L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

Port L supports Multi-Input Wakeup (MIWU) on all eight pins. L4 and L5 are used for the timer input functions T2A and T2B. L0 and L1 are not available on the 44-pin version of the COP888CF, since they are replaced by V_{REF} and AGND. L0 and L1 are not terminated on the 44-pin version. Consequently, reading L0 or L1 as inputs will return unreliable data with the 44-pin package, so this data should be masked out with user software when the L port is read for input data. It is recommended that the pins be configured as outputs.

Port L has the following alternate features:

L0	MIWU
L1	MIWU
L2	MIWU
L3	MIWU
L4	MIWU or T2A
L5	MIWU or T2B
L6	MIWU
L7	MIWU

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOOUT WatchDog output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin, but is also used to bring the device out of HALT mode with a low to high transition on G7. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin or general purpose input (R/C clock configuration), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

G0	INTR (External Interrupt Input)
G2	T1B (Timer T1 Capture Input)
G3	T1A (Timer T1 I/O)
G4	SO (MICROWIRE Serial Data Output)
G5	SK (MICROWIRE Serial Clock)
G6	SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

G1	WDOOUT WatchDog and/or Clock Monitor dedicated output
G7	CKO Oscillator dedicated output or general purpose input

Port C is an 8-bit I/O port. The 40-pin device does not have a full complement of Port C pins. The unavailable pins are not terminated. A read operation for these unterminated pins will return unpredictable values.

Pin Descriptions (Continued)

Port I is an 8-bit Hi-Z input port, and also provides the analog inputs to the A/D converter. The 28-pin device does not have a full complement of Port I pins. The unavailable pins are not terminated (i.e. they are floating). A read operation from these unterminated pins will return unpredictable values. The user should ensure that the software takes this into account by either masking out these inputs, or else restricting the accesses to bit operations only. If unterminated, Port I pins will draw power only when addressed.

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Functional Description

The architecture of the COP888CF is modified Harvard architecture. With the Harvard architecture, the control store program memory (ROM) is separated from the data store memory (RAM). Both ROM and RAM have their own separate addressing space with separate address buses. The COP888CF architecture, though based on Harvard architecture, permits transfer of data from ROM to RAM.

CPU REGISTERS

The CPU can do an 8-bit addition, subtraction, logical or shift operation in one instruction (t_c) cycle time.

There are five CPU registers:

A is the 8-bit Accumulator Register

PC is the 15-bit Program Counter Register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is an 8-bit RAM address pointer, which can be optionally post auto incremented or decremented.

X is an 8-bit alternate RAM address pointer, which can be optionally post auto incremented or decremented.

SP is the 8-bit stack pointer, which points to the subroutine/interrupt stack (in RAM). The SP is initialized to RAM address 06F with reset.

All the CPU registers are memory mapped with the exception of the Accumulator (A) and the Program Counter (PC).

PROGRAM MEMORY

Program memory for the COP888CF consists of 4096 bytes of ROM. These bytes may hold program instructions or constant data (data tables for the LAID instruction, jump vectors for the JID instruction, and interrupt vectors for the VIS instruction). The program memory is addressed by the 15-bit program counter (PC). All interrupts in the COP888CF vector to program memory location 0FF Hex.

DATA MEMORY

The data memory address space includes the on-chip RAM and data registers, the I/O registers (Configuration, Data and Pin), the control registers, the MICROWIRE/PLUS SIO shift register, and the various registers, and counters associated with the timers (with the exception of the IDLE timer). Data memory is addressed directly by the instruction or indirectly by the B, X and SP pointers.

The COP888CF has 128 bytes of RAM. Sixteen bytes of RAM are mapped as "registers" at addresses 0F0 to 0FF Hex. These registers can be loaded immediately, and also decremented and tested with the DRSZ (decrement register and skip if zero) instruction. The memory pointer registers X, SP, and B are memory mapped into this space at address locations 0FC to 0FE Hex respectively, with the other registers (other than reserved register 0FF) being available for general usage.

The instruction set of the COP888CF permits any bit in memory to be set, reset or tested. All I/O and registers on the COP888CF (except A and PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested. The accumulator (A) bits can also be directly and individually tested.

Reset

The RESET input when pulled low initializes the microcontroller. Initialization will occur whenever the RESET input is pulled low. Upon initialization, the data and configuration registers for Ports L, G, and C are cleared, resulting in these Ports being initialized to the TRI-STATE mode. Pin G1 of the G Port is an exception (as noted below) since pin G1 is dedicated as the WatchDog and/or Clock Monitor error output pin. Port D is initialized high with RESET. The PC, PSW, CNTRL, ICNTRL, and T2CNTRL control registers are cleared. The Multi-Input Wakeup registers WKEN, WKEDG, and WKPND are cleared. The A/D control register ENAD is cleared, resulting in the ADC being powered down initially. The Stack Pointer, SP, is initialized to 06F Hex.

The COP888CF comes out of reset with both the WatchDog logic and the Clock Monitor detector armed, and with both the WatchDog service window bits set and the Clock Monitor bit set. The WatchDog and Clock Monitor detector circuits are inhibited during reset. The WatchDog service window bits are initialized to the maximum WatchDog service window of 64k t_c clock cycles. The Clock Monitor bit is initialized high, and will cause a Clock Monitor error following reset if the clock has not reached the minimum specified frequency at the termination of reset. A Clock Monitor error will cause an active low error output on pin G1. This error output will continue until 16–32 t_c clock cycles following the clock frequency reaching the minimum specified value, at which time the G1 output will enter the TRI-STATE mode.

The external RC network shown in Figure 5 should be used to ensure that the RESET pin is held low until the power supply to the chip stabilizes.

TL/DD/9425-7

$RC > 5 \times$ Power Supply Rise Time

FIGURE 5. Recommended Reset Circuit

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock (1/t_c).

Figure 6 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table A shows the component values required for various standard crystal values.

R/C OSCILLATOR

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart pin.

Table B shows the variation in the oscillator frequencies as functions of the component (R and C) values.

FIGURE 6. Crystal and R/C Oscillator Diagrams

TABLE A. Crystal Oscillator Configuration, T_A = 25°C

R1 (kΩ)	R2 (MΩ)	C1 (pF)	C2 (pF)	CKI Freq (MHz)	Conditions
0	1	30	30-36	10	V _{CC} = 5V
0	1	30	30-36	4	V _{CC} = 5V
0	1	200	100-150	0.455	V _{CC} = 5V

TABLE B. R/C Oscillator Configuration, T_A = 25°C

R (kΩ)	C (pF)	CKI Freq (MHz)	Instr. Cycle (μs)	Conditions
3.3	82	2.2 to 2.7	3.7 to 4.6	V _{CC} = 5V
5.6	100	1.1 to 1.3	7.4 to 9.0	V _{CC} = 5V
6.8	100	0.9 to 1.1	8.8 to 10.8	V _{CC} = 5V

Note: 3k ≤ R ≤ 200k
50 pF ≤ C ≤ 200 pF

Current Drain

The total current drain of the chip depends on:

1. Oscillator operation mode—I1
2. Internal switching current—I2
3. Internal leakage current—I3
4. Output source current—I4
5. DC current caused by external input not at V_{CC} or GND—I5

6. DC reference current contribution from the A/D converter—I6
7. Clock Monitor current when enabled—I7

Thus the total current drain, I_t, is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5 + I_6 + I_7$$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw more current as the CKI input frequency increases up to the maximum 10 MHz value. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

where C = equivalent capacitance of the chip
V = operating voltage
f = CKI frequency

Control Registers

CNTRL Register (Address X'00EE)

The Timer1 (T1) and MICROWIRE/PLUS control register contains the following bits:

- SL1 & SL0 Select the MICROWIRE/PLUS clock divide by (00 = 2, 01 = 4, 1x = 8)
- IEDG External interrupt edge polarity select (0 = Rising edge, 1 = Falling edge)
- MSEL Selects G5 and G4 as MICROWIRE/PLUS signals SK and SO respectively
- T1C0 Timer T1 Start/Stop control in timer modes 1 and 2
Timer T1 Underflow Interrupt Pending Flag in timer mode 3
- T1C1 Timer T1 mode control bit
- T1C2 Timer T1 mode control bit
- T1C3 Timer T1 mode control bit

T1C3	T1C2	T1C1	T1C0	MSEL	IEDG	SL1	SL0
Bit 7				Bit 0			

PSW Register (Address X'00EF)

The PSW register contains the following select bits:

- GIE Global interrupt enable (enables interrupts)
- EXEN Enable external interrupt
- BUSY MICROWIRE/PLUS busy shifting flag
- EXPND External interrupt pending
- T1ENA Timer T1 Interrupt Enable for Timer Underflow or T1A Input capture edge
- T1PND A Timer T1 Interrupt Pending Flag (Autoreload RA in mode 1, T1 Underflow in Mode 2, T1A capture edge in mode 3)

- C Carry Flag
- HC Half Carry Flag

HC	C	T1PND A	T1ENA	EXPND	BUSY	EXEN	GIE
Bit 7				Bit 0			

Control Registers (Continued)

The Half-Carry bit is also affected by all the instructions that affect the Carry flag. The SC (Set Carry) and RC (Reset Carry) instructions will respectively set or clear both the carry flags. In addition to the SC and RC instructions, ADC, SUBC, RRC and RLC instructions affect the carry and Half Carry flags.

ICNTRL Register (Address X'00E8)

The ICNTRL register contains the following bits:

T1ENB	Timer T1 Interrupt Enable for T1B Input capture edge
T1PNDB	Timer T1 Interrupt Pending Flag for T1B capture edge
μ WEN	Enable MICROWIRE/PLUS interrupt
μ WPND	MICROWIRE/PLUS interrupt pending
T0EN	Timer T0 Interrupt Enable (Bit 12 toggle)
T0PND	Timer T0 Interrupt pending
LPEN	L Port Interrupt Enable (Multi-Input Wakeup/Interrupt)

Bit 7 could be used as a flag

Unused	LPEN	T0PND	T0EN	μ WPND	μ WEN	T1PNDB	T1ENB
Bit 7							Bit 0

T2CNTRL Register (Address X'00C6)

The T2CNTRL register contains the following bits:

T2ENB	Timer T2 Interrupt Enable for T2B Input capture edge
T2PNDB	Timer T2 Interrupt Pending Flag for T2B capture edge
T2ENA	Timer T2 Interrupt Enable for Timer Underflow or T2A Input capture edge
T2PND	Timer T2 Interrupt Pending Flag (Autoreload RA in mode 1, T2 Underflow in mode 2, T2A capture edge in mode 3)
T2C0	Timer T2 Start/Stop control in timer modes 1 and 2 Timer T2 Underflow Interrupt Pending Flag in timer mode 3
T2C1	Timer T2 mode control bit
T2C2	Timer T2 mode control bit
T2C3	Timer T2 mode control bit

T2C3	T2C2	T2C1	T2C0	T2PND	T2ENA	T2PNDB	T2ENB
Bit 7							Bit 0

Timers

The COP888CF contains a very versatile set of timers (T0, T1, T2). All timers and associated autoreload/capture registers power up containing random data.

Figure 7 shows a block diagram for the timers on the COP888CF.

TIMER T0 (IDLE TIMER)

The COP888CF supports applications that require maintaining real time and low power with the IDLE mode. This IDLE mode support is furnished by the IDLE timer T0, which is a 16-bit timer. The Timer T0 runs continuously at the fixed rate of the instruction cycle clock, t_c . The user cannot read or write to the IDLE Timer T0, which is a count down timer.

The Timer T0 supports the following functions:

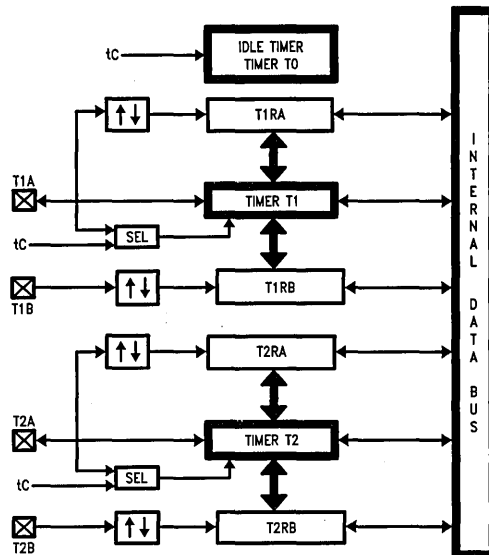

- Exit out of the Idle Mode (See Idle Mode description)
- WatchDog logic (See WatchDog description)
- Start up delay out of the HALT mode

The IDLE Timer T0 can generate an interrupt when the thirteenth bit toggles. This toggle is latched into the TOPND pending flag, and will occur every 4 ms at the maximum clock frequency ($t_c = 1 \mu\text{s}$). A control flag T0EN allows the interrupt from the thirteenth bit of Timer T0 to be enabled or disabled. Setting T0EN will enable the interrupt, while resetting it will disable the interrupt.

TIMER T1 AND TIMER T2

The COP888CF has a set of two powerful timer/counter blocks, T1 and T2. The associated features and functioning of a timer block are described by referring to the timer block Tx. Since the two timer blocks, T1 and T2, are identical, all comments are equally applicable to either timer block.

Each timer block consists of a 16-bit timer, Tx, and two supporting 16-bit autoreload/capture registers, RxA and RxB. Each timer block has two pins associated with it, TxA and TxB. The pin TxA supports I/O required by the timer block, while the pin TxB is an input to the timer block. The powerful and flexible timer block allows the COP888CF to

TL/DD/9425-11

FIGURE 7. Timers for the COP888CF

easily perform all timer functions with minimal software overhead. The timer block has three operating modes: Processor Independent PWM mode, External Event Counter mode, and Input Capture mode.

The control bits TxC3, TxC2, and TxC1 allow selection of the different modes of operation.

Timers (Continued)

Mode 1. Processor Independent PWM Mode

As the name suggests, this mode allows the COP888CF to generate a PWM signal with very minimal user intervention. The user only has to define the parameters of the PWM signal (ON time and OFF time). Once begun, the timer block will continuously generate the PWM signal completely independent of the microcontroller. The user software services the timer block only when the PWM parameters require updating.

In this mode the timer Tx counts down at a fixed rate of t_c . Upon every underflow the timer is alternately reloaded with the contents of supporting registers, RxA and RxB. The very first underflow of the timer causes the timer to reload from the register RxA. Subsequent underflows cause the timer to be reloaded from the registers alternately beginning with the register RxB.

The Tx Timer control bits, TxC3, TxC2 and TxC1 set up the timer for PWM mode operation.

Figure 8 shows a block diagram of the timer in PWM mode. The underflows can be programmed to toggle the TxA output pin. The underflows can also be programmed to generate interrupts.

Underflows from the timer are alternately latched into two pending flags, TxPND A and TxPND B. The user must reset these pending flags under software control. Two control enable flags, TxENA and TxENB, allow the interrupts from the timer underflow to be enabled or disabled. Setting the timer enable flag TxENA will cause an interrupt when a timer underflow causes the RxA register to be reloaded into the timer. Setting the timer enable flag TxENB will cause an interrupt when a timer underflow causes the RxB register to be reloaded into the timer. Resetting the timer enable flags will disable the associated interrupts.

Either or both of the timer underflow interrupts may be enabled. This gives the user the flexibility of interrupting once per PWM period on either the rising or falling edge of the PWM output. Alternatively, the user may choose to interrupt on both edges of the PWM output.

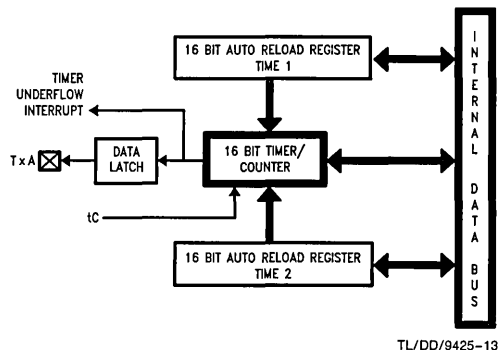

FIGURE 8. Timer in PWM Mode

Mode 2. External Event Counter Mode

This mode is quite similar to the processor independent PWM mode described above. The main difference is that the timer, Tx, is clocked by the input signal from the TxA pin. The Tx timer control bits, TxC3, TxC2 and TxC1 allow the

timer to be clocked either on a positive or negative edge from the TxA pin. Underflows from the timer are latched into the TxPND A pending flag. Setting the TxENA control flag will cause an interrupt when the timer underflows.

In this mode the input pin TxB can be used as an independent positive edge sensitive interrupt input if the TxENB control flag is set. The occurrence of a positive edge on the TxB input pin is latched into the TxPND B flag.

Figure 9 shows a block diagram of the timer in External Event Counter mode.

Note: The PWM output is not available in this mode since the TxA pin is being used as the counter input clock.

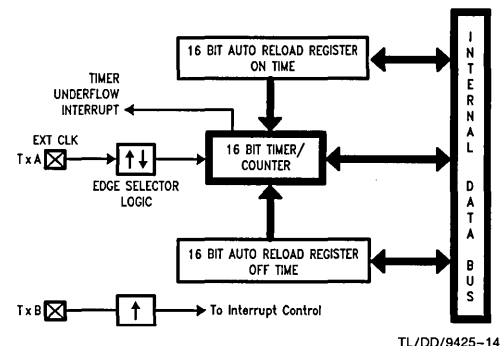

FIGURE 9. Timer in External Event Counter Mode

Mode 3. Input Capture Mode

The COP888CF can precisely measure external frequencies or time external events by placing the timer block, Tx, in the input capture mode.

In this mode, the timer Tx is constantly running at the fixed t_c rate. The two registers, RxA and RxB, act as capture registers. Each register acts in conjunction with a pin. The register RxA acts in conjunction with the TxA pin and the register RxB acts in conjunction with the TxB pin.

The timer value gets copied over into the register when a trigger event occurs on its corresponding pin. Control bits, TxC3, TxC2 and TxC1, allow the trigger events to be specified either as a positive or a negative edge. The trigger condition for each input pin can be specified independently.

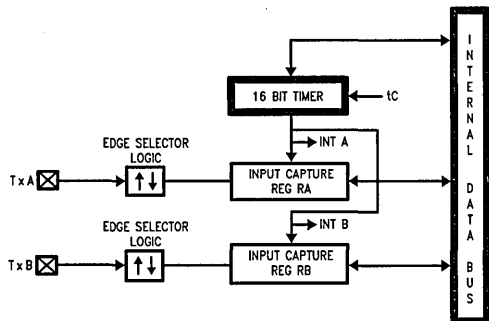

The trigger conditions can also be programmed to generate interrupts. The occurrence of the specified trigger condition on the TxA and TxB pins will be respectively latched into the pending flags, TxPND A and TxPND B. The control flag TxENA allows the interrupt on TxA to be either enabled or disabled. Setting the TxENA flag enables interrupts to be generated when the selected trigger condition occurs on the TxA pin. Similarly, the flag TxENB controls the interrupts from the TxB pin.

Underflows from the timer can also be programmed to generate interrupts. Underflows are latched into the timer TxCO pending flag (the TxCO control bit serves as the timer underflow interrupt pending flag in the Input Capture mode). Consequently, the TxCO control bit should be reset when entering the Input Capture mode. The timer underflow interrupt is enabled with the TxENA control flag. When a TxA interrupt occurs in the Input Capture mode, the user must check both

Timers (Continued)

whether a TxA input capture or a timer underflow (or both) caused the interrupt.

Figure 10 shows a block diagram of the timer in Input Capture mode.

TL/DD/9425-15

FIGURE 10. Timer in Input Capture Mode

TIMER CONTROL FLAGS

The timers T1 and T2 have identical control structures. The control bits and their functions are summarized below.

- TxC0 Timer Start/Stop control in Modes 1 and 2 (Processor Independent PWM and External Event Counter), where 1 = Start, 0 = Stop
Timer Underflow Interrupt Pending Flag in Mode 3 (Input Capture)
- TxPND A Timer Interrupt Pending Flag
- TxPND B Timer Interrupt Pending Flag
- TxENA Timer Interrupt Enable Flag
- TxENB Timer Interrupt Enable Flag
1 = Timer Interrupt Enabled
0 = Timer Interrupt Disabled
- TxC3 Timer mode control
- TxC2 Timer mode control
- TxC1 Timer mode control

The timer mode control bits (TxC3, TxC2 and TxC1) are detailed below:

TxC3	TxC2	TxC1	Timer Mode	Interrupt A Source	Interrupt B Source	Timer Counts On
0	0	0	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Pos. Edge
0	0	1	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Neg. Edge
1	0	1	MODE 1 (PWM) TxA Toggle	Autoreload RA	Autoreload RB	t_c
1	0	0	MODE 1 (PWM) No TxA Toggle	Autoreload RA	Autoreload RB	t_c
0	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Pos. Edge	Pos. TxA Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Neg. Edge	Pos. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c
0	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Pos. Edge	Neg. TxB Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Neg. Edge	Neg. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c

Power Save Modes

The COP888CF offers the user two power save modes of operation: HALT and IDLE. In the HALT mode, all microcontroller activities are stopped. In the IDLE mode, the on-board oscillator circuitry and timer T0 are active but all other microcontroller activities are stopped. In either mode, all on-board RAM, registers, I/O states, and timers (with the exception of T0) are unaltered.

HALT MODE

The COP888CF is placed in the HALT mode by writing a "1" to the HALT flag (G7 data bit). All microcontroller activities, including the clock, timers, and A/D converter, are stopped. The WatchDog logic on the COP888CF is disabled during the HALT mode. However, the clock monitor circuitry if enabled remains active and will cause the WatchDog output pin (WDOUT) to go low. If the HALT mode is used and the user does not want to activate the WDOUT pin, the Clock Monitor should be disabled after the device comes out of reset (resetting the Clock Monitor control bit with the first write to the WDSVR register). In the HALT mode, the power requirements of the COP888CF are minimal and the applied voltage (V_{CC}) may be decreased to V_r ($V_r = 2.0V$) without altering the state of the machine.

The COP888CF supports three different ways of exiting the HALT mode. The first method of exiting the HALT mode is with the Multi-Input Wakeup feature on the L port. The second method is with a low to high transition on the CKO (G7) pin. This method precludes the use of the crystal clock configuration (since CKO becomes a dedicated output), and so may be used with an RC clock configuration. The third method of exiting the HALT mode is by pulling the RESET pin low.

Since a crystal or ceramic resonator may be selected as the oscillator, the Wakeup signal is not allowed to start the chip running immediately since crystal oscillators and ceramic resonators have a delayed start up time to reach full amplitude and frequency stability. The IDLE timer is used to generate a fixed delay to ensure that the oscillator has indeed stabilized before allowing instruction execution. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry is enabled. The IDLE timer is loaded with a value of 256 and is clocked with the t_c instruction cycle clock. The t_c clock is derived by dividing the oscillator clock down by a factor of 10. The Schmitt trigger following the CKI inverter on the chip ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If an RC clock option is being used, the fixed delay is introduced optionally. A control bit, CLKDLY, mapped as configuration bit G7, controls whether the delay is to be introduced or not. The delay is included if CLKDLY is set, and excluded if CLKDLY is reset. The CLKDLY bit is cleared on reset.

The COP888CF has two mask options associated with the HALT mode. The first mask option enables the HALT mode feature, while the second mask option disables the HALT mode. With the HALT mode enable mask option, the COP888CF will enter and exit the HALT mode as described above. With the HALT disable mask option, the COP888CF cannot be placed in the HALT mode (writing a "1" to the HALT flag will have no effect).

The WatchDog detector circuit is inhibited during the HALT mode. However, the clock monitor circuit if enabled remains active during HALT mode in order to ensure a clock monitor error if the COP888CF inadvertently enters the HALT mode as a result of a runaway program or power glitch.

IDLE MODE

The COP888CF is placed in the IDLE mode by writing a "1" to the IDLE flag (G6 data bit). In this mode, all activity, except the associated on-board oscillator circuitry, the WatchDog logic, the clock monitor and the IDLE Timer T0, is stopped. The power supply requirements of the microcontroller in this mode of operation are typically around 30% of normal power requirement of the microcontroller.

As with the HALT mode, the COP888CF can be returned to normal operation with a reset, or with a Multi-Input Wakeup from the L Port. Alternately, the microcontroller resumes normal operation from the IDLE mode when the thirteenth bit (representing 4.096 ms at internal clock frequency of 1 MHz, $t_c = 1 \mu s$) of the IDLE Timer toggles.

This toggle condition of the thirteenth bit of the IDLE Timer T0 is latched into the TOPND pending flag.

The user has the option of being interrupted with a transition on the thirteenth bit of the IDLE Timer T0. The interrupt can be enabled or disabled via the T0EN control bit. Setting the T0EN flag enables the interrupt and vice versa.

The user can enter the IDLE mode with the Timer T0 interrupt enabled. In this case, when the TOPND bit gets set, the COP888CF will first execute the Timer T0 interrupt service routine and then return to the instruction following the "Enter Idle Mode" instruction.

Alternatively, the user can enter the IDLE mode with the IDLE Timer T0 interrupt disabled. In this case, the COP888CF will resume normal operation with the instruction immediately following the "Enter IDLE Mode" instruction.

Note: It is necessary to program two NOP instructions following both the set HALT mode and set IDLE mode instructions. These NOP instructions are necessary to allow clock resynchronization following the HALT or IDLE modes.

Multi-Input Wakeup

The Multi-Input Wakeup feature is used to return (wakeup) the COP888CF from either the HALT or IDLE modes. Alternately Multi-Input Wakeup/Interrupt feature may also be used to generate up to 8 edge selectable external interrupts.

Figure 11 shows the Multi-Input Wakeup logic for the COP888CF microcontroller.

The Multi-Input Wakeup feature utilizes the L Port. The user selects which particular L port bit (or combination of L Port bits) will cause the COP888CF to exit the HALT or IDLE modes. The selection is made via the Reg: WKEN. The Reg: WKEN is an 8-bit read/write register, which contains a control bit for every L port bit. Setting a particular WKEN bit enables a Wakeup from the associated L port pin.

The user can select whether the trigger condition on the selected L Port pin is going to be either a positive edge (low to high transition) or a negative edge (high to low transition). This selection is made via the Reg: WKEDG, which is an 8-bit control register with a bit assigned to each L Port pin. Setting the control bit will select the trigger condition to be a negative edge on that particular L Port pin. Resetting the bit selects the trigger condition to be a positive edge. Changing an edge select entails several steps in order to avoid a pseudo Wakeup condition as a result of the edge change. First, the associated WKEN bit should be reset, followed by the edge select change in WKEDG. Next, the associated WKPND bit should be cleared, followed by the associated WKEN bit being re-enabled.

An example may serve to clarify this procedure. Suppose we wish to change the edge select from positive (low going high) to negative (high going low) for L Port bit 5, where bit 5 has previously been enabled for an input interrupt. The program would be as follows:

```

RBIT 5, WKEN
SBIT 5, WKEDG
RBIT 5, WKPND
SBIT 5, WKEN
  
```

If the L port bits have been used as outputs and then changed to inputs with Multi-Input Wakeup/Interrupt, a safety procedure should also be followed to avoid inherited pseudo wakeup conditions. After the selected L port bits have been changed from output to input but before the associated WKEN bits are enabled, the associated edge select bits in WKEDG should be set or reset for the desired edge selects, followed by the associated WKPND bits being cleared.

This same procedure should be used following reset, since the L port inputs are left floating as a result of reset.

The occurrence of the selected trigger condition for Multi-Input Wakeup is latched into a pending register called WKPND. The respective bits of the WKPND register will be set on the occurrence of the selected trigger edge on the corresponding Port L pin. The user has the responsibility of clearing these pending flags. Since WKPND is a pending register for the occurrence of selected wakeup conditions, the COP888CF will not enter the HALT mode if any Wakeup bit is both enabled and pending. Consequently, the user has the responsibility of clearing the pending flags before attempting to enter the HALT mode.

The WKEN, WKPND and WKEDG are all read/write registers, and are cleared at reset.

PORT L INTERRUPTS

Port L provides the user with an additional eight fully selectable, edge sensitive interrupts which are all vectored into the same service subroutine.

The interrupt from Port L shares logic with the wake up circuitry. The register WKEN allows interrupts from Port L to be individually enabled or disabled. The register WKEDG specifies the trigger condition to be either a positive or a negative edge. Finally, the register WKPND latches in the pending trigger conditions.

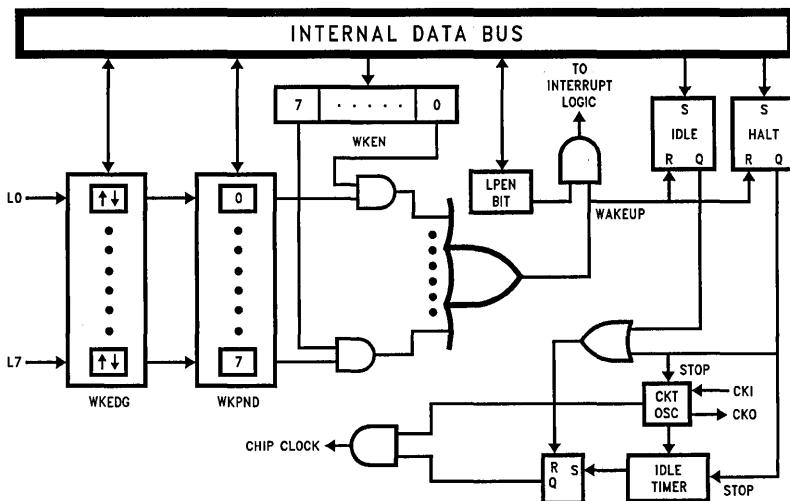

FIGURE 11. Multi-Input Wake Up Logic

TL/DD/9425-16

Multi-Input Wakeup (Continued)

The GIE (global interrupt enable) bit enables the interrupt function. A control flag, LPEN, functions as a global interrupt enable for Port L interrupts. Setting the LPEN flag will enable interrupts and vice versa. A separate global pending flag is not needed since the register WKPND is adequate.

Since Port L is also used for waking the COP888CF out of the HALT or IDLE modes, the user can elect to exit the HALT or IDLE modes either with or without the interrupt enabled. If he elects to disable the interrupt, then the COP888CF will restart execution from the instruction immediately following the instruction that placed the microcontroller in the HALT or IDLE modes. In the other case, the COP888CF will first execute the interrupt service routine and then revert to normal operation.

The Wakeup signal will not start the chip running immediately since crystal oscillators or ceramic resonators have a finite start up time. The IDLE Timer (T0) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the COP888CF to execute instructions. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry and the IDLE Timer T0 are enabled. The IDLE Timer is loaded with a value of 256 and is clocked from the t_c instruction cycle clock. The t_c clock is derived by dividing down the oscillator clock by a factor of 10. A Schmitt trigger following the CKI on-chip inverter ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If the RC clock option is used, the fixed delay is under software control. A control flag, CLKDLY, in the G7 configuration bit allows the clock start up delay to be optionally inserted. Setting CLKDLY flag high will cause clock start up delay to be inserted and resetting it will exclude the clock start up delay. The CLKDLY flag is cleared during reset, so the clock start up delay is not present following reset with the RC clock options.

A/D Converter

The COP888CF contains an 8-channel, multiplexed input, successive approximation, A/D converter. Two dedicated pins, V_{REF} and AGND are provided for voltage reference.

OPERATING MODES

The A/D converter supports ratiometric measurements. It supports both Single Ended and Differential modes of operation.

Four specific analog channel selection modes are supported. These are as follows:

Allow any specific channel to be selected at one time. The A/D converter performs the specific conversion requested and stops.

Allow any specific channel to be scanned continuously. In other words, the user will specify the channel and the A/D converter will keep on scanning it continuously. The user can come in at any arbitrary time and immediately read the result of the last conversion. The user does not have to wait for the current conversion to be completed.

Allow any differential channel pair to be selected at one time. The A/D converter performs the specific differential conversion requested and stops.

Allow any differential channel pair to be scanned continuously. In other words, the user will specify the differential channel pair and the A/D converter will keep on scanning it continuously. The user can come in at any arbitrary time and immediately read the result of the last differential conversion. The user does not have to wait for the current conversion to be completed.

The A/D converter is supported by two memory mapped registers, the result register and the mode control register. When the COP888CF is reset, the control register is cleared and the A/D is powered down. The A/D result register has unknown data following reset.

A/D Control Register

A control register, Reg: ENAD, contains 3 bits for channel selection, 3 bits for prescaler selection, and 2 bits for mode selection. An A/D conversion is initiated by writing to the ENAD control register. The result of the conversion is available to the user from the A/D result register, Reg: ADRSLT.

Reg: ENAD

CHANNEL SELECT	MODE SELECT	PRESCALER SELECT
Bits 7, 6, 5	Bits 4,3	Bits 2, 1, 0

CHANNEL SELECT

This 3-bit field selects one of eight channels to be the V_{IN+}. The mode selection determines the V_{IN-} input.

Single Ended mode:

Bit 7	Bit 6	Bit 5	Channel No.
0	0	0	0
0	0	1	1
0	1	0	2
0	1	1	3
1	0	0	4
1	0	1	5
1	1	0	6
1	1	1	7

Differential mode:

Bit 7	Bit 6	Bit 5	Channel Pairs (+, -)
0	0	0	0, 1
0	0	1	1, 0
0	1	0	2, 3
0	1	1	3, 2
1	0	0	4, 5
1	0	1	5, 4
1	1	0	6, 7
1	1	1	7, 6

MODE SELECT

This 2-bit field is used to select the mode of operation (single conversion, continuous conversions, differential, single ended) as shown in the following table.

Bit 4	Bit 3	Mode
0	0	Single Ended mode, single conversion
0	1	Single Ended mode, continuous scan of a single channel into the result register
1	0	Differential mode, single conversion
1	1	Differential mode, continuous scan of a channel pair into the result register

A/D Converter (Continued)

PRESCALER SELECT

This 3-bit field is used to select one of the seven prescaler clocks for the A/D converter. The prescaler also allows the A/D clock inhibit power saving mode to be selected. The following table shows the various prescaler options.

Bit 2	Bit 1	Bit 0	Clock Select
0	0	0	Inhibit A/D clock
0	0	1	Divide by 1
0	1	0	Divide by 2
0	1	1	Divide by 4
1	0	0	Divide by 6
1	0	1	Divide by 12
1	1	0	Divide by 8
1	1	1	Divide by 16

ADC Operation

The A/D converter interface works as follows. Writing to the A/D control register ENAD initiates an A/D conversion unless the prescaler value is set to 0, in which case the ADC clock is stopped and the ADC is powered down. The conversion sequence starts at the beginning of the write to ENAD operation powering up the ADC. At the first falling edge of the converter clock following the write operation (not counting the falling edge if it occurs at the same time as the write operation ends), the sample signal turns on for two clock cycles. The ADC is selected in the middle of the sample period. If the ADC is in single conversion mode, the conversion complete signal from the ADC will generate a power down for the A/D converter. If the ADC is in continuous mode, the conversion complete signal will restart the conversion sequence by deselecting the ADC for one converter clock cycle before starting the next sample. The ADC 8-bit result is loaded into the A/D result register (ADRSLT) except during LOAD clock high, which prevents transient data (resulting from the ADC writing a new result over an old one) being read from ADRSLT.

PRESCALER

The COP888CF A/D Converter (ADC) contains a prescaler option which allows seven different clock selections. The A/D clock frequency is equal to CKI divided by the prescaler value. Note that the prescaler value must be chosen such that the A/D clock falls within the specified range. The maximum A/D frequency is 1.67 MHz. This equates to a 600 ns ADC clock cycle.

The A/D converter takes 12 ADC clock cycles to complete a conversion. Thus the minimum ADC conversion time for the COP888CF is $7.2 \mu\text{s}$ when a prescaler of 6 has been selected. These 12 ADC clock cycles necessary for a conversion consist of 1 cycle at the beginning for reset, 2 cycles for sampling, 8 cycles for converting, and 1 cycle for loading the result into the COP888CF A/D result register (ADRSLT). This A/D result register is a read-only register. The COP888CF cannot write into ADRSLT.

The prescaler also allows an A/D clock inhibit option, which saves power by powering down the A/D when it is not in use.

Note: The A/D converter is also powered down when the COP888CF is in either the HALT or IDLE modes. If the ADC is running when the COP888CF enters the HALT or IDLE modes, the ADC will power down during the HALT or IDLE, and then will reinitialize the conversion when the COP888CF comes out of the HALT or IDLE modes.

Analog Input and Source Resistance Considerations

Figure 12 shows the A/D pin model for the COP888CF in single ended mode. The differential mode has similar A/D pin model. The leads to the analog inputs should be kept as short as possible. Both noise and digital clock coupling to an A/D input can cause conversion errors. The clock lead should be kept away from the analog input line to reduce coupling. The A/D channel input pins do not have any internal output driver circuitry connected to them because this circuitry would load the analog input signals due to output buffer leakage current.

Source impedances greater than $1 \text{ k}\Omega$ on the analog input lines will adversely affect internal RC charging time during input sampling. As shown in Figure 12, the analog switch to the DAC array is closed only during the 2 A/D cycle sample time. Large source impedances on the analog inputs may result in the DAC array not being charged to the correct voltage levels, causing scale errors.

If large source resistance is necessary, the recommended solution is to slow down the A/D clock speed in proportion to the source resistance. The A/D converter may be operated at the maximum speed for R_S less than $1 \text{ k}\Omega$. For R_S greater than $1 \text{ k}\Omega$, A/D clock speed needs to be reduced. For example, with $R_S = 2 \text{ k}\Omega$, the A/D converter may be operated at half the maximum speed. A/D converter clock speed may be slowed down by either increasing the A/D prescaler divide-by or decreasing the CKI clock frequency. The A/D clock speed may be reduced to its minimum frequency of 100 kHz.

*The analog switch is closed only during the sample time.

FIGURE 12. A/D Pin Model (Single Ended Mode)

TL/DD/9425-28

Interrupts

The COP888CF supports a vectored interrupt scheme. It supports a total of ten interrupt sources. The following table lists all the possible COP888CF interrupt sources, their arbitration ranking and the memory locations reserved for the interrupt vector for each source.

Two bytes of program memory space are reserved for each interrupt source. All interrupt sources except the software interrupt are maskable. Each of the maskable interrupts have an Enable bit and a Pending bit. A maskable interrupt is active if its associated enable and pending bits are set. If $GIE = 1$ and an interrupt is active, then the processor will be interrupted as soon as it is ready to start executing an instruction except if the above conditions happen during the Software Trap service routine. This exception is described in the Software Trap sub-section.

The interruption process is accomplished with the INTR instruction (opcode 00), which is jammed inside the Instruction Register and replaces the opcode about to be executed. The following steps are performed for every interrupt:

1. The GIE (Global Interrupt Enable) bit is reset.
2. The address of the instruction about to be executed is pushed into the stack.
3. The PC (Program Counter) branches to address 00FF. This procedure takes $7 t_c$ cycles to execute.

At this time, since $GIE = 0$, other maskable interrupts are disabled. The user is now free to do whatever context switching is required by saving the context of the machine in the stack with PUSH instructions. The user would then program a VIS (Vector Interrupt Select) instruction in order to branch to the interrupt service routine of the highest priority interrupt enabled and pending at the time of the VIS. Note that this is not necessarily the interrupt that caused the branch to address location 00FF Hex prior to the context switching.

Thus, if an interrupt with a higher rank than the one which caused the interruption becomes active before the decision of which interrupt to service is made by the VIS, then the interrupt with the higher rank will override any lower ones and will be acknowledged. The lower priority interrupt(s) are still pending, however, and will cause another interrupt immediately following the completion of the interrupt service routine associated with the higher priority interrupt just serviced. This lower priority interrupt will occur immediately following the RETI (Return from Interrupt) instruction at the end of the interrupt service routine just completed.

Inside the interrupt service routine, the associated pending bit has to be cleared by software. The RETI (Return from Interrupt) instruction at the end of the interrupt service routine will set the GIE (Global Interrupt Enable) bit, allowing the processor to be interrupted again if another interrupt is active and pending.

The VIS instruction looks at all the active interrupts at the time it is executed and performs an indirect jump to the beginning of the service routine of the one with the highest rank.

The addresses of the different interrupt service routines, called vectors, are chosen by the user and stored in ROM in a table starting at 01E0 (assuming that VIS is located between 00FF and 01DF). The vectors are 15-bit wide and therefore occupy 2 ROM locations.

VIS and the vector table must be located in the same 256-byte block (0y00 to 0yFF) except if VIS is located at the last address of a block. In this case, the table must be in the next block. The vector table cannot be inserted in the first 256-byte block.

The vector of the maskable interrupt with the lowest rank is located at 0yE0 (Hi-Order byte) and 0yE1 (Lo-Order byte) and so forth in increasing rank number. The vector of the

Arbitration Ranking	Source	Description	Vector Address Hi-Low Byte
(1) Highest	Software	INTR Instruction	0yFE–0yFF
	Reserved	for Future Use	0yFC–0yFD

Interrupts (Continued)

FIGURE 13. COP888CF Interrupt Block Diagram

TL/DD/9425-18

maskable interrupt with the highest rank is located at 0yFA (Hi-Order byte) and 0yFB (Lo-Order byte).

The Software Trap has the highest rank and its vector is located at 0yFE and 0yFF.

If, by accident, a VIS gets executed and no interrupt is active, then the PC (Program Counter) will branch to a vector located at 0yE0-0yE1. This vector can point to the Software Trap (ST) interrupt service routine, or to another special service routine as desired.

Figure 13 shows the COP888CF Interrupt block diagram.

SOFTWARE TRAP

The Software Trap (ST) is a special kind of non-maskable interrupt which occurs when the INTR instruction (used to acknowledge interrupts) is fetched from ROM and placed inside the instruction register. This may happen when the PC is pointing beyond the available ROM address space or when the stack is over-popped.

When an ST occurs, the user can re-initialize the stack pointer and do a recovery procedure (similar to RESET, but not necessarily containing all of the same initialization procedures) before restarting.

The occurrence of an ST is latched into the ST pending bit. The GIE bit is not affected and the ST pending bit (**not accessible by the user**) is used to inhibit other interrupts and to direct the program to the ST service routine with the VIS instruction. The RPND instruction is used to clear the software interrupt pending bit. This bit is also cleared on reset.

The ST has the highest rank among all interrupts.

Nothing (except another ST) can interrupt an ST being serviced.

WatchDog

The COP888CF contains a WatchDog and clock monitor. The WatchDog is designed to detect the user program getting stuck in infinite loops resulting in loss of program control or "runaway" programs. The Clock Monitor is used to

detect the absence of a clock or a very slow clock below a specified rate on the CKI pin.

The WatchDog consists of two independent logic blocks: WD UPPER and WD LOWER. WD UPPER establishes the upper limit on the service window and WD LOWER defines the lower limit of the service window.

Servicing the WatchDog consists of writing a specific value to a WatchDog Service Register named WDSVR which is memory mapped in the RAM. This value is composed of three fields, consisting of a 2-bit Window Select, a 5-bit Key Data field, and the 1-bit Clock Monitor Select field. Table I shows the WDSVR register.

The lower limit of the service window is fixed at 2048 instruction cycles. Bits 7 and 6 of the WDSVR register allow the user to pick an upper limit of the service window.

Table II shows the four possible combinations of lower and upper limits for the WatchDog service window. This flexibility in choosing the WatchDog service window prevents any undue burden on the user software.

Bits 5, 4, 3, 2 and 1 of the WDSVR register represent the 5-bit Key Data field. The key data is fixed at 01100. Bit 0 of the WDSVR Register is the Clock Monitor Select bit.

TABLE I. WatchDog Service Register

Window Select		Key Data					Clock Monitor
X	X	0	1	1	0	0	Y
7	6	5	4	3	2	1	0

TABLE II. WatchDog Service Window Select

WDSVR Bit 7	WDSVR Bit 6	Service Window (Lower-Upper Limits)
0	0	2k-8k t_c Cycles
0	1	2k-16k t_c Cycles
1	0	2k-32k t_c Cycles
1	1	2k-64k t_c Cycles

Clock Monitor

The Clock Monitor aboard the COP888CF can be selected or deselected under program control. The Clock Monitor is guaranteed not to reject the clock if the instruction cycle clock ($1/t_c$) is greater or equal to 10 kHz. This equates to a clock input rate on CKI of greater or equal to 100 kHz.

WATCHDOG Operation

The WATCHDOG and Clock Monitor are disabled during reset. The COP888CF comes out of reset with the WATCHDOG armed, the WATCHDOG Window Select (bits 6, 7 of the WDSVR Register) set, and the Clock Monitor bit (bit 0 of the WDSVR Register) enabled. Thus, a Clock Monitor error will occur after coming out of reset, if the instruction cycle clock frequency has not reached a minimum specified value, including the case where the oscillator fails to start.

The WDSVR register can be written to only once after reset and the key data (bits 5 through 1 of the WDSVR Register) must match to be a valid write. This write to the WDSVR register involves two irrevocable choices: (i) the selection of the WATCHDOG service window (ii) enabling or disabling of the Clock Monitor. Hence, the first write to WDSVR Register involves selecting or deselecting the Clock Monitor, select the WATCHDOG service window and match the WATCHDOG key data. Subsequent writes to the WDSVR register will compare the value being written by the user to the WATCHDOG service window value and the key data (bits 7 through 1) in the WDSVR Register. Table III shows the sequence of events that can occur.

The user must service the WATCHDOG at least once before the upper limit of the service window expires. The WATCHDOG may not be serviced more than once in every lower limit of the service window. The user may service the WATCHDOG as many times as wished in the time period between the lower and upper limits of the service window. The first write to the WDSVR Register is also counted as a WATCHDOG service.

The WATCHDOG has an output pin associated with it. This is the WDOOUT pin, on pin 1 of the port G. WDOOUT is active low. The WDOOUT pin is in the high impedance state in the inactive state. Upon triggering the WATCHDOG, the logic will pull the WDOOUT (G1) pin low for an additional $16 t_c$ – $32 t_c$ cycles after the signal level on WDOOUT pin goes below the lower Schmitt trigger threshold. After this delay, the COP888CF will stop forcing the WDOOUT output low.

The WATCHDOG service window will restart when the WDOOUT pin goes high. It is recommended that the user tie the WDOOUT pin back to V_{CC} through a resistor in order to pull WDOOUT high.

A WATCHDOG service while the WDOOUT signal is active will be ignored. The state of the WDOOUT pin is not guaranteed on reset, but if it powers up low then the WATCHDOG will time out and WDOOUT will enter high impedance state.

The Clock Monitor forces the G1 pin low upon detecting a clock frequency error. The Clock Monitor error will continue until the clock frequency has reached the minimum specified value, after which the G1 output will enter the high impedance TRI-STATE mode following $16 t_c$ – $32 t_c$ clock cycles. The Clock Monitor generates a continual Clock Monitor error if the oscillator fails to start, or fails to reach the minimum specified frequency. The specification for the Clock Monitor is as follows:

$1/t_c > 10$ kHz—No clock rejection.

$1/t_c < 10$ Hz—Guaranteed clock rejection.

WATCHDOG AND CLOCK MONITOR SUMMARY

The following salient points regarding the COP888 WATCHDOG and CLOCK MONITOR should be noted:

- Both the WATCHDOG and Clock Monitor detector circuits are inhibited during RESET.
- Following RESET, the WATCHDOG and CLOCK MONITOR are both enabled, with the WATCHDOG having the maximum service window selected.
- The WATCHDOG service window and Clock Monitor enable/disable option can only be changed once, during the initial WATCHDOG service following RESET.
- The initial WATCHDOG service must match the key data value in the WATCHDOG Service register WDSVR in order to avoid a WATCHDOG error.
- Subsequent WATCHDOG services must match all three data fields in WDSVR in order to avoid WATCHDOG errors.
- The correct key data value cannot be read from the WATCHDOG Service register WDSVR. Any attempt to read this key data value of 01100 from WDSVR will read as key data value of all 0's.
- The WATCHDOG detector circuit is inhibited during both the HALT and IDLE modes.
- The Clock Monitor detector circuit is active during both the HALT and IDLE modes. Consequently, the COP888 inadvertently entering the HALT mode will be detected as a Clock Monitor error (provided that the Clock Monitor enable option has been selected by the program).
- With the single-pin R/C oscillator mask option selected and the CLKDLY bit reset, the WATCHDOG service window will resume following HALT mode from where it left off before entering the HALT mode.

TABLE III. WATCHDOG Service Actions

Key Data	Window Data	Clock Monitor	Action
Match	Match	Match	Valid Service: Restart Service Window
Don't Care	Mismatch	Don't Care	Error: Generate WATCHDOG Output
Mismatch	Don't Care	Don't Care	Error: Generate WATCHDOG Output
Don't Care	Don't Care	Mismatch	Error: Generate WATCHDOG Output

WATCHDOG Operation (Continued)

- With the crystal oscillator mask option selected, or with the single-pin R/C oscillator mask option selected and the CLKDLY bit set, the WATCHDOG service window will be set to its selected value from WDSVR following HALT. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following HALT, but must be serviced within the selected window to avoid a WATCHDOG error.
- The IDLE timer T0 is not initialized with RESET.
- The user can sync in to the IDLE counter cycle with an IDLE counter (T0) interrupt or by monitoring the T0PND flag. The T0PND flag is set whenever the thirteenth bit of the IDLE counter toggles (every 4096 instruction cycles). The user is responsible for resetting the T0PND flag.
- A hardware WATCHDOG service occurs just as the COP888 exits the IDLE mode. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following IDLE, but must be serviced within the selected window to avoid a WATCHDOG error.
- Following RESET, the initial WATCHDOG service (where the service window and the CLOCK MONITOR enable/disable must be selected) may be programmed anywhere within the maximum service window (65,536 instruction cycles) initialized by RESET. Note that this initial WATCHDOG service may be programmed within the initial 2048 instruction cycles without causing a WATCHDOG error.

Detection of Illegal Conditions

The COP888CF can detect various illegal conditions resulting from coding errors, transient noise, power supply voltage drops, runaway programs, etc.

Reading of undefined ROM gets zeros. The opcode for software interrupt is zero. If the program fetches instructions from undefined ROM, this will force a software interrupt, thus signaling that an illegal condition has occurred.

The subroutine stack grows down for each call (jump to subroutine), interrupt, or PUSH, and grows up for each return or POP. The stack pointer is initialized to RAM location 06F Hex during reset. Consequently, if there are more returns than calls, the stack pointer will point to addresses 070 and 071 Hex (which are undefined RAM). Undefined RAM from addresses 070 to 07F Hex is read as all 1's, which in turn will cause the program to return to address 7FFF Hex. This is an undefined ROM location and the instruction fetched (all 0's) from this location will generate a software interrupt signaling an illegal condition.

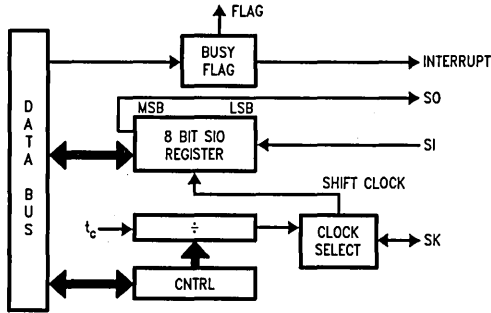

Thus, the chip can detect the following illegal conditions:

- Executing from undefined ROM
- Over "POP"ing the stack by having more returns than calls.

When the software interrupt occurs, the user can re-initialize the stack pointer and do a recovery procedure before restarting (this recovery program is probably similar to that following reset, but might not contain the same program initialization procedures).

MICROWIRE/PLUS

MICROWIRE/PLUS is a serial synchronous communications interface. The MICROWIRE/PLUS capability enables the COP888CF to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, E²PROMs etc.) and with other microcontrollers which support the MICROWIRE interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 14 shows a block diagram of the MICROWIRE/PLUS logic.

TL/DD/9425-20

FIGURE 14. MICROWIRE/PLUS Block Diagram

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS arrangement with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE/PLUS arrangement with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. In the master mode the SK clock rate is selected by the two bits, SL0 and SL1, in the CNTRL register. TABLE IV details the different clock rates that may be selected.

TABLE IV. MICROWIRE/PLUS Master Mode Clock Selection

SL1	SL0	SK
0	0	$2 \times t_c$
0	1	$4 \times t_c$
1	x	$8 \times t_c$

Where t_c is the instruction cycle clock

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. If enabled, an interrupt is generated when eight data bits have been shifted. The COP888CF may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. Figure 15 shows how two COP888CF microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangements.

Warning:

The SIO register should only be loaded when the SK clock is low. Loading the SIO register while the SK clock is high will result in undefined data in the SIO register. SK clock is normally low when not shifting.

Setting the BUSY flag when the input SK clock is high in the MICROWIRE/PLUS slave mode may cause the current SK clock for the SIO shift register to be narrow. For safety, the BUSY flag should only be set when the input SK clock is low.

MICROWIRE/PLUS Master Mode Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the COP888CF. The MICROWIRE Master always initiates all data exchanges. The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table V summarizes the bit settings required for Master mode of operation.

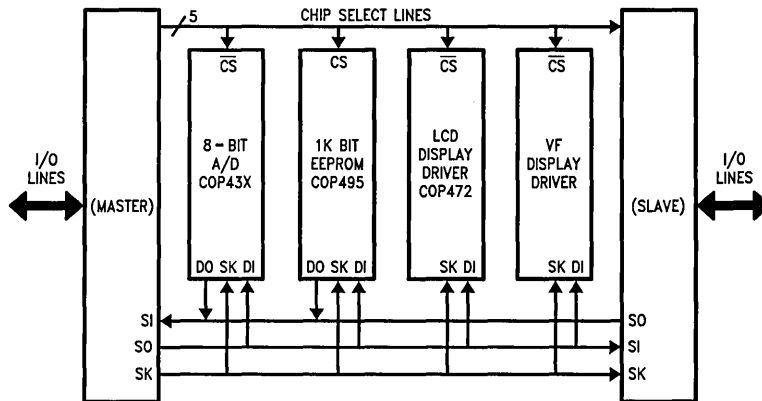

FIGURE 15. MICROWIRE/PLUS Application

TL/DD/9425-21

MICROWIRE/PLUS (Continued)**MICROWIRE/PLUS Slave Mode Operation**

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by setting and resetting the appropriate bit in the Port G configuration register. Table V summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated.

Alternate SK Phase Operation

The COP888CF allows either the normal SK clock or an alternate phase SK clock to shift data in and out of the SIO register. In both the modes the SK is normally low. In the normal mode data is shifted in on the rising edge of the SK clock and the data is shifted out on the falling edge of the SK clock. The SIO register is shifted on each falling edge of the SK clock in the normal mode. In the alternate SK phase mode the SIO register is shifted on the rising edge of the SK clock.

A control flag, SKSEL, allows either the normal SK clock or the alternate SK clock to be selected. Resetting SKSEL causes the MICROWIRE/PLUS logic to be clocked from the normal SK signal. Setting the SKSEL flag selects the alternate SK clock. The SKSEL is mapped into the G6 configuration bit. The SKSEL flag will power up in the reset condition, selecting the normal SK signal.

TABLE V

This table assumes that the control flag MSEL is set.

G4 (SO) Config. Bit	G5 (SK) Config. Bit	G4 Fun.	G5 Fun.	Operation
1	1	SO	Int. SK	MICROWIRE/PLUS Master
0	1	TRI-STATE	Int. SK	MICROWIRE/PLUS Master
1	0	SO	Ext. SK	MICROWIRE/PLUS Slave
0	0	TRI-STATE	Ext. SK	MICROWIRE/PLUS Slave

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space

Address	Contents
00 to 6F	On-Chip RAM bytes
70 to BF	Unused RAM Address Space
C0	Timer T2 Lower Byte
C1	Timer T2 Upper Byte
C2	Timer T2 Autoload Register T2RA Lower Byte
C3	Timer T2 Autoload Register T2RA Upper Byte
C4	Timer T2 Autoload Register T2RB Lower Byte
C5	Timer T2 Autoload Register T2RB Upper Byte
C6	Timer T2 Control Register
C7	WATCHDOG Service Register (Reg:WDSVR)
C8	MIWU Edge Select Register (Reg:WKEDG)
C9	MIWU Enable Register (Reg:WKEN)
CA	MIWU Pending Register (Reg:WKPND)
CB	A/D Converter Control Register (Reg:ENAD)
CC	A/D Converter Result Register (Reg:ADRSLT)
CD to CF	Reserved
D0	Port L Data Register
D1	Port L Configuration Register
D2	Port L Input Pins (Read Only)
D3	Reserved for Port L
D4	Port G Data Register
D5	Port G Configuration Register
D6	Port G Input Pins (Read Only)
D7	Port I Input Pins (Read Only)
D8	Port C Data Register
D9	Port C Configuration Register
DA	Port C Input Pins (Read Only)
DB	Reserved for Port C
DC	Port D Data Register
DD to DF	Reserved for Port D
E0 to E5	Reserved
E6	Timer T1 Autoload Register T1RB Lower Byte
E7	Timer T1 Autoload Register T1RB Upper Byte
E8	ICNTRL Register
E9	MICROWIRE Shift Register
EA	Timer T1 Lower Byte
EB	Timer T1 Upper Byte
EC	Timer T1 Autoload Register T1RA Lower Byte
ED	Timer T1 Autoload Register T1RA Upper Byte
EE	CNTRL Control Register
EF	PSW Register
F0 to FB	On-Chip RAM Mapped as Registers
FC	X Register
FD	SP Register
FE	B Register
FF	Reserved

Reading memory locations 70-7F Hex will return all ones. Reading other unused memory locations will return undefined data.

Addressing Modes

The COP888CF has ten addressing modes, six for operand addressing and four for transfer of control.

OPERAND ADDRESSING MODES

Register Indirect

This is the "normal" addressing mode for the COP888CF. The operand is the data memory addressed by the B pointer or X pointer.

Register Indirect (with auto post increment or decrement of pointer)

This addressing mode is used with the LD and X instructions. The operand is the data memory addressed by the B pointer or X pointer. This is a register indirect mode that automatically post increments or decrements the B or X register after executing the instruction.

Direct

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

Immediate

The instruction contains an 8-bit immediate field as the operand.

Short Immediate

This addressing mode is used with the Load B Immediate instruction. The instruction contains a 4-bit immediate field as the operand.

Indirect

This addressing mode is used with the LAID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a data operand from the program memory.

TRANSFER OF CONTROL ADDRESSING MODES

Relative

This mode is used for the JP instruction, with the instruction field being added to the program counter to get the new program location. JP has a range from -31 to +32 to allow a 1-byte relative jump (JP + 1 is implemented by a NOP instruction). There are no "pages" when using JP, since all 15 bits of PC are used.

Absolute

This mode is used with the JMP and JSR instructions, with the instruction field of 12 bits replacing the lower 12 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory segment.

Absolute Long

This mode is used with the JMPL and JSRL instructions, with the instruction field of 15 bits replacing the entire 15 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory space.

Indirect

This mode is used with the JID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a location in the program memory. The contents of this program memory location serve as a partial address (lower 8 bits of PC) for the jump to the next instruction.

Note: The VIS is a special case of the Indirect Transfer of Control addressing mode, where the double byte vector associated with the interrupt is transferred from adjacent addresses in the program memory into the program counter (PC) in order to jump to the associated interrupt service routine.

Instruction Set

Register and Symbol Definition

Registers	
A	8-Bit Accumulator Register
B	8-Bit Address Register
X	8-Bit Address Register
SP	8-Bit Stack Pointer Register
PC	15-Bit Program Counter Register
PU	Upper 7 Bits of PC
PL	Lower 8 Bits of PC
C	1 Bit of PSW Register for Carry
HC	1 Bit of PSW Register for Half Carry
GIE	1 Bit of PSW Register for Global Interrupt Enable
VU	Interrupt Vector Upper Byte
VL	Interrupt Vector Lower Byte

Symbols	
[B]	Memory Indirectly Addressed by B Register
[X]	Memory Indirectly Addressed by X Register
MD	Direct Addressed Memory
Mem	Direct Addressed Memory or [B]
MemI	Direct Addressed Memory or [B] or Immediate Data
Imm	8-Bit Immediate Data
Reg	Register Memory: Addresses F0 to FF (Includes B, X and SP)
Bit	Bit Number (0 to 7)
←	Loaded with
↔	Exchanged with

NOP		No Operation	PC ← PC + 1

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instructions taking two bytes).

Most single byte instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

Bytes and Cycles per Instruction

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

Where,

i is the immediate data

Md is a directly addressed memory location

* is an unused opcode

Note: The opcode 60 Hex is also the opcode for IFBIT #i,A

Mask Options

The COP888CF mask programmable options are shown below. The options are programmed at the same time as the ROM pattern submission.

OPTION 1: CLOCK CONFIGURATION

- = 1 Crystal Oscillator (CKI/10)
 - G7 (CKO) is clock generator output to crystal/resonator
 - CKI is the clock input
- = 2 Single-pin RC controlled oscillator (CKI/10)
 - G7 is available as a HALT restart and/or general purpose input

OPTION 2: HALT

- = 1 Enable HALT mode
- = 2 Disable HALT mode

OPTION 3: COP888CF BONDING

- = 1 44-Pin PLCC
- = 2 40-Pin DIP
- = 3 N/A
- = 4 28-Pin DIP
- = 5 28-Pin SO

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (if clock option-1 has been selected). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface or maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bar graph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use window interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC® via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS 232 serial interface cable.
MHW-PS3	Power supply 110V/60 Hz
MHW-PS4	Power supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MHW-884CF28D5PC	28 DIP	4.5V-5.5V	COP884CF
MHW-884CF28DWPC	28 DIP	2.5V-6.0V	COP884CF
MHW-888CF40D5PC	40 DIP	4.5V-5.5V	COP888CF
MHW-888CF40DWPC	40 DIP	2.5V-6.0V	COP888CF
MWH-888CF44D5PC	44 PLCC	4.5V-5.5V	COP888CF
MHW-888CF44DWPC	44 PLCC	2.5V-6.0V	COP888CF

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM®, PC/XT®, PC-AT® or compatible.	424410527-001

Development Support (Continued)

SIMULATOR

The COP8 Designer's Tool Kit is available for evaluating National Semiconductor's COP8 microcontroller family. The kit contains programmer's manuals, device datasheets, pocket reference guide, assembler and simulator, which allows the user to write, test, debug and run code on an industry standard compatible PC. The simulator has a windowed user interface and can handle script files that simulate hardware inputs, interrupts and automatic command processing. The capture file feature enables the user to record to a file current cycle count and output port changes which are caused by the program under test.

Simulator Ordering Information

Part Number	Description	Manual
COP8-TOOL-KIT	COP8 Designer's Tool Kit Assembler and Simulator	420420270-001 424420269-001

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific datasheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board, which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

Single Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP888CFMHEL-X	X = 1: crystal X = 3: R/C	44 LDCC	Multi-Chip Module (MCM), UV erasable	COP888CF
COP888CFMHD-X	X = 1: crystal X = 3: R/C	40 DIP	MCM, UV erasable	COP888CF
COP884CFMHD-X	X = 1: crystal X = 3: R/C	28 DIP	MCM, UV erasable	COP884CF

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator Board for 28 DIP Multi-Chip Module (MCM) and for use with Scrambler Boards	COP884CFMHD
COP8-SCRM-DIP	MCM Scrambler Board for 40 DIP socket	COP888CFMHD
COP8-SCRM-PCC	MCM Scrambler Board for 44 PLCC/LDCC	COP888CFMHEL
COP8-SCRM-SBX	Hybrid Scrambler Board for 28 LCC Socket	COP884CFMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler Board	COP884CFMHD, COP888CFMHD
COP8-PRGM-PCC	Duplicator Board with COP8-SCRM-PCC Scrambler Board	COP888CFMEL, COP884CFMHD

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package Contents:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 Baud

Set-Up: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hours, 7 Days

COP884CG/COP888CG

Single-Chip microCMOS Microcontrollers

General Description

The COP888 family of microcontrollers uses an 8-bit single chip core architecture fabricated with National Semiconductor's M²CMOSTM process technology. The COP888CG is a member of this expandable 8-bit core processor family of microcontrollers. (Continued)

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μ s instruction cycle time
- 4096 bytes on-board ROM (COP888CG)
- 192 bytes on-board RAM (COP888CG)
- Single supply operation: 2.5V-6V
- Full duplex UART
- Two analog comparators
- MICROWIRE/PLUSTM serial I/O
- WATCHDOGTM and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Fourteen multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Three Timers (Each with 2 Interrupts)
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - UART (2)
 - Default VIS
- Versatile instruction set
- True bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 PLCC or 40 N or 28 N or 28 PLCC
 - 44 PLCC with 39 I/O pins
 - 40 N with 35 I/O pins
 - 28 N with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Temperature ranges: -40°C to +85°C, -55°C to +125°C
- Form factor emulation devices
- Real time emulation and full program debug offered by National's Development Systems

Block Diagram

FIGURE 1. COP888CG Block Diagram

TL/DD/9765-1

General Description (Continued)

They are fully static parts, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS serial I/O, three 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), full duplex UART, two comparators, and two power savings modes

(HALT and IDLE), both with a multi-sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The devices operate over a voltage range of 2.5V to 6V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

TL/DD/9765-7

FIGURE 2. MICROWIRE/PLUS Timing

Pin Descriptions

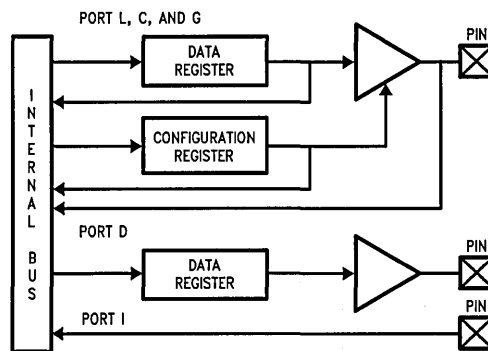

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The COP888CG contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input (Schmitt trigger inputs on ports L and G), output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. (See the memory map for the various addresses associated with the I/O ports.) Figure 3 shows the I/O port configurations. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

TL/DD/9765-8

FIGURE 3. I/O Port Configurations

PORT L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

The Port L supports Multi-Input Wake Up on all eight pins. L1 is used for the UART external clock. L2 and L3 are used for the UART transmit and receive. L4 and L5 are used for the timer input functions T2A and T2B. L6 and L7 are used for the timer input functions T3A and T3B.

The Port L has the following alternate features:

- L0 MIWU
- L1 MIWU or CKX
- L2 MIWU or TDX
- L3 MIWU or RDX
- L4 MIWU or T2A
- L5 MIWU or T2B
- L6 MIWU or T3A
- L7 MIWU or T3B

Port G is an 8-bit port with 5 I/O pins (G0, G2-G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2-G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOUT WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin but is also used to bring the device out of HALT mode with a low to high transition on G7. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2-G5) can be individually configured under software control.

Pin Descriptions (Continued)

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin (crystal clock option) or general purpose input (R/C clock option), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE™ Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

- G1 WDOOUT WATCHDOG and/or Clock Monitor dedicated output
- G7 CKO Oscillator dedicated output or general purpose input

Port C is an 8-bit I/O port. The 40-pin device does not have a full complement of Port C pins. The unavailable pins are not terminated. A read operation for these unterminated pins will return unpredictable values.

PORT I is an eight-bit Hi-Z input port. The 28-pin device does not have a full complement of Port I pins. The unavailable pins are not terminated i.e., they are floating. A read operation for these unterminated pins will return unpredictable values. The user must ensure that the software takes this into account by either masking or restricting the accesses to bit operations. The unterminated Port I pins will draw power only when addressed.

Port I1–I3 are used for Comparator 1. Port I4–I6 are used for Comparator 2.

The Port I has the following alternate features.

- I1 COMP1–IN (Comparator 1 Negative Input)
- I2 COMP1+IN (Comparator 1 Positive Input)
- I3 COMP1OUT (Comparator 1 Output)
- I4 COMP2–IN (Comparator 2 Negative Input)
- I5 COMP2+IN (Comparator 2 Positive Input)
- I6 COMP2OUT (Comparator 2 Output)

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Functional Description

The architecture of the COP888CG is modified Harvard architecture. With the Harvard architecture, the control store program memory (ROM) is separated from the data store memory (RAM). Both ROM and RAM have their own separate addressing space with separate address buses. The architecture, though based on Harvard architecture, permits transfer of data from ROM to RAM.

CPU REGISTERS

The CPU can do an 8-bit addition, subtraction, logical or shift operation in one instruction (t_c) cycle time.

There are six CPU registers:

A is the 8-bit Accumulator Register

PC is the 15-bit Program Counter Register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is an 8-bit RAM address pointer, which can be optionally post auto incremented or decremented.

X is an 8-bit alternate RAM address pointer, which can be optionally post auto incremented or decremented.

SP is the 8-bit stack pointer, which points to the subroutine/interrupt stack (in RAM). The SP is initialized to RAM address 06F with reset.

S is the 8-bit Data Segment Address Register used to extend the lower half of the address range (00 to 7F) into 256 data segments of 128 bytes each.

All the CPU registers are memory mapped with the exception of the Accumulator (A) and the Program Counter (PC).

PROGRAM MEMORY

The program memory consists of 4096 bytes of ROM. These bytes may hold program instructions or constant data (data tables for the LAID instruction, jump vectors for the JID instruction, and interrupt vectors for the VIS instruction). The program memory is addressed by the 15-bit program counter (PC). All interrupts in the devices vector to program memory location 0FF Hex.

DATA MEMORY

The data memory address space includes the on-chip RAM and data registers, the I/O registers (Configuration, Data and Pin), the control registers, the MICROWIRE/PLUS SIO shift register, and the various registers, and counters associated with the timers (with the exception of the IDLE timer). Data memory is addressed directly by the instruction or indirectly by the B, X, SP pointers and S register.

The COP888CG has 192 bytes of RAM. Sixteen bytes of RAM are mapped as "registers" at addresses 0F0 to 0FF Hex. These registers can be loaded immediately, and also decremented and tested with the DRSZ (decrement register and skip if zero) instruction. The memory pointer registers X, SP, B and S are memory mapped into this space at address locations 0FC to 0FF Hex respectively, with the other registers being available for general usage.

The instruction set permits any bit in memory to be set, reset or tested. All I/O and registers (except A and PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested. The accumulator (A) bits can also be directly and individually tested.

Data Memory Segment RAM Extension

Data memory address 0FF is used as a memory mapped location for the Data Segment Address Register (S).

The data store memory is either addressed directly by a single byte address within the instruction, or indirectly relative to the reference of the B, X, or SP pointers (each contains a single-byte address). This single-byte address allows an addressing range of 256 locations from 00 to FF hex. The upper bit of this single-byte address divides the data store memory into two separate sections as outlined previously. With the exception of the RAM register memory from address locations 00F0 to 00FF, all RAM memory is memory mapped with the upper bit of the single-byte address being equal to zero. This allows the upper bit of the single-byte address to determine whether or not the base address range (from 0000 to 00FF) is extended. If this upper bit equals one (representing address range 0080 to 00FF), then address extension does not take place. Alternatively, if this upper bit equals zero, then the data segment extension register S is used to extend the base address range (from 0000 to 007F) from XX00 to XX7F, where XX represents the 8 bits from the S register. Thus the 128-byte data segment extensions are located from addresses 0100 to 017F for data segment 1, 0200 to 027F for data segment 2, etc., up to FF00 to FF7F for data segment 255. The base address range from 0000 to 007F represents data segment 0.

Figure 4 illustrates how the S register data memory extension is used in extending the lower half of the base address range (00 to 7F hex) into 256 data segments of 128 bytes each, with a total addressing range of 32 kbytes from XX00 to XX7F. This organization allows a total of 256 data segments of 128 bytes each with an additional upper base segment of 128 bytes. Furthermore, all addressing modes are available for all data segments. The S register must be changed under program control to move from one data segment (128 bytes) to another. However, the upper base segment (containing the 16 memory registers, I/O registers, control registers, etc.) is always available regardless of the contents of the S register, since the upper base segment (address range 0080 to 00FF) is independent of data segment extension.

The instructions that utilize the stack pointer (SP) always reference the stack as part of the base segment (Segment 0), regardless of the contents of the S register. The S register is not changed by these instructions. Consequently, the stack (used with subroutine linkage and interrupts) is always located in the base segment. The stack pointer will be initialized to point at data memory location 006F as a result of reset.

The 128 bytes of RAM contained in the base segment are split between the lower and upper base segments. The first 116 bytes of RAM are resident from address 0000 to 006F in the lower base segment, while the remaining 16 bytes of RAM represent the 16 data memory registers located at addresses 00F0 to 00FF of the upper base segment. No RAM is located at the upper sixteen addresses (0070 to 007F) of the lower base segment.

Additional RAM beyond these initial 128 bytes, however, will always be memory mapped in groups of 128 bytes (or less) at the data segment address extensions (XX00 to XX7F) of the lower base segment. The additional 64 bytes of RAM in

the COP888CG (beyond the initial 128 bytes) are memory mapped at address locations 0100 to 013F hex.

TL/DD/9765-9

*Reads as all ones.

FIGURE 4. RAM Organization

Reset

The **RESET** input when pulled low initializes the microcontroller. Initialization will occur whenever the **RESET** input is pulled low. Upon initialization, the data and configuration registers for ports L, G and C are cleared, resulting in these Ports being initialized to the TRI-STATE mode. Pin G1 of the G Port is an exception (as noted below) since pin G1 is dedicated as the WATCHDOG and/or Clock Monitor error output pin. Port D is set high. The PC, PSW, ICNTRL, CNTRL, T2CNTRL and T3CNTRL control registers are cleared. The UART registers PSR, ENU (except that TBMT bit is set), ENUR and ENUL are cleared. The Comparator Select Register is cleared. The S register is initialized to zero. The Multi-Input Wakeup registers WKEN, WKEDG and WKPND are cleared. The stack pointer, SP, is initialized to 6F Hex.

The device comes out of reset with both the WATCHDOG logic and the Clock Monitor detector armed, with the WATCHDOG service window bits set and the Clock Monitor bit set. The WATCHDOG and Clock Monitor circuits are inhibited during reset. The WATCHDOG service window bits being initialized high default to the maximum WATCHDOG service window of 64k t_C clock cycles. The Clock Monitor bit being initialized high will cause a Clock Monitor error following reset if the clock has not reached the minimum specified frequency at the termination of reset. A Clock Monitor error will cause an active low error output on pin G1. This error output will continue until 16 t_C –32 t_C clock cycles following the clock frequency reaching the minimum specified value, at which time the G1 output will enter the TRI-STATE mode.

The external RC network shown in Figure 5 should be used to ensure that the **RESET** pin is held low until the power supply to the chip stabilizes.

Reset (Continued)

 $RC > 5 \times \text{Power Supply Rise Time}$
FIGURE 5. Recommended Reset Circuit

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Figure 6 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table A shows the component values required for various standard crystal values.

R/C OSCILLATOR

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart input.

Table B shows the variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/9765-11
FIGURE 6. Crystal and R/C Oscillator Diagrams

TABLE A. Crystal Oscillator Configuration, $T_A = 25^\circ\text{C}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)	Conditions
0	1	30	30-36	10	$V_{CC} = 5V$
0	1	30	30-36	4	$V_{CC} = 5.0V$
0	1	200	100-150	0.455	$V_{CC} = 5V$

TABLE B. RC Oscillator Configuration, $T_A = 25^\circ\text{C}$

R (k Ω)	C (pF)	CKI Freq (MHz)	Instr. Cycle (μs)	Conditions
3.3	82	2.2 to 2.7	3.7 to 4.6	$V_{CC} = 5V$
5.6	100	1.1 to 1.3	7.4 to 9.0	$V_{CC} = 5V$
6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5V$

Note: $3k \leq R \leq 200k$
 $50 \text{ pF} \leq C \leq 200 \text{ pF}$

Current Drain

The total current drain of the chip depends on:

1. Oscillator operation mode—I1
2. Internal switching current—I2
3. Internal leakage current—I3
4. Output source current—I4
5. DC current caused by external input not at V_{CC} or GND—I5
6. Comparator DC supply current when enabled—I6
7. Clock Monitor current when enabled—I7

Thus the total current drain, I_t , is given as
 $I_t = I_1 + I_2 + I_3 + I_4 + I_5 + I_6 + I_7$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw more current as the CKI input frequency increases up to the maximum 10 MHz value. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

where C = equivalent capacitance of the chip
 V = operating voltage
 f = CKI frequency

Some sample current drain values at $V_{CC} = 5V$ are:

CKI (MHz)	Inst. Cycle (μs)	I_t (mA)
10	1	15
3.58	2.8	5.4
2	5	3
0.3	33	0.45
0 (HALT)	—	<0.001 (typ.)

Control Registers

CNTRL Register (Address X'00EE)

The Timer1 (T1) and MICROWIRE/PLUS control register contains the following bits:

- SL1 & SL0 Select the MICROWIRE/PLUS clock divide by (00 = 2, 01 = 4, 1x = 8)
- IEDG External interrupt edge polarity select (0 = Rising edge, 1 = Falling edge)
- MSEL Selects G5 and G4 as MICROWIRE/PLUS signals SK and SO respectively
- T1C0 Timer T1 Start/Stop control in timer modes 1 and 2
Timer T1 Underflow Interrupt Pending Flag in timer mode 3
- T1C1 Timer T1 mode control bit
- T1C2 Timer T1 mode control bit
- T1C3 Timer T1 mode control bit

T1C3	T1C2	T1C1	T1C0	MSEL	IEDG	SL1	SL0
Bit 7						Bit 0	

Control Registers (Continued)

PSW Register (Address X'00EF)

The PSW register contains the following select bits:

GIE	Global interrupt enable (enables interrupts)
EXEN	Enable external interrupt
BUSY	MICROWIRE/PLUS busy shifting flag
EXPND	External interrupt pending
T1ENA	Timer T1 Interrupt Enable for Timer Underflow or T1A Input capture edge
T1PNDA	Timer T1 Interrupt Pending Flag (Autoreload RA in mode 1, T1 Underflow in Mode 2, T1A capture edge in mode 3)
C	Carry Flag
HC	Half Carry Flag

HC	C	T1PNDA	T1ENA	EXPND	BUSY	EXEN	GIE
Bit 7				Bit 0			

The Half-Carry bit is also affected by all the instructions that affect the Carry flag. The SC (Set Carry) and RC (Reset Carry) instructions will respectively set or clear both the carry flags. In addition to the SC and RC instructions, ADC, SUBC, RRC and RLC instructions affect the carry and Half Carry flags.

ICNTRL Register (Address X'00E8)

The ICNTRL register contains the following bits:

T1ENB	Timer T1 Interrupt Enable for T1B Input capture edge
T1PNDB	Timer T1 Interrupt Pending Flag for T1B capture edge
μ WEN	Enable MICROWIRE/PLUS interrupt
μ WPND	MICROWIRE/PLUS interrupt pending
TOEN	Timer T0 Interrupt Enable (Bit 12 toggle)
T0PND	Timer T0 Interrupt pending
LPEN	L Port Interrupt Enable (Multi-Input Wakeup/Interrupt)
Bit 7 could be used as a flag	

Unused	LPEN	T0PND	TOEN	μ WPND	μ WEN	T1PNDB	T1ENB
Bit 7				Bit 0			

T2CNTRL Register (Address X'00C6)

The T2CNTRL register contains the following bits:

T2ENB	Timer T2 Interrupt Enable for T2B Input capture edge
T2PNDB	Timer T2 Interrupt Pending Flag for T2B capture edge
T2ENA	Timer T2 Interrupt Enable for Timer Underflow or T2A Input capture edge
T2PNDA	Timer T2 Interrupt Pending Flag (Autoreload RA in mode 1, T2 Underflow in mode 2, T2A capture edge in mode 3)
T2C0	Timer T2 Start/Stop control in timer modes 1 and 2 Timer T2 Underflow Interrupt Pending Flag in timer mode 3

T2C1	Timer T2 mode control bit
T2C2	Timer T2 mode control bit
T2C3	Timer T2 mode control bit

T2C3	T2C2	T2C1	T2C0	T2PNDA	T2ENA	T2PNDB	T2ENB
Bit 7							Bit 0

T3CNTRL Register (Address X'00B6)

The T3CNTRL register contains the following bits:

T3ENB	Timer T3 Interrupt Enable for T3B
T3PNDB	Timer T3 Interrupt Pending Flag for T3B pin (T3B capture edge)
T3ENA	Timer T3 Interrupt Enable for Timer Underflow or T3A pin
T3PNDA	Timer T3 Interrupt Pending Flag (Autoload RA in mode 1, T3 Underflow in mode 2, T3a capture edge in mode 3)
T3C0	Timer T3 Start/Stop control in timer modes 1 and 2 Timer T3 Underflow Interrupt Pending Flag in timer mode 3
T3C1	Timer T3 mode control bit
T3C2	Timer T3 mode control bit
T3C3	Timer T3 mode control bit

T3C3	T3C2	T3C1	T3C0	T3PNDA	T3ENA	T3PNDB	T3ENB
Bit 7							Bit 0

Timers

The COP888CG contains a very versatile set of timers (T0, T1, T2, T3). All timers and associated autoreload/capture registers power up containing random data.

TIMER T0 (IDLE TIMER)

The devices support applications that require maintaining real time and low power with the IDLE mode. This IDLE mode support is furnished by the IDLE timer T0, which is a 16-bit timer. The Timer T0 runs continuously at the fixed rate of the instruction cycle clock, t_c . The user cannot read or write to the IDLE Timer T0, which is a count down timer. The Timer T0 supports the following functions:

Exit out of the Idle Mode (See Idle Mode description)
WATCHDOG logic (See WATCHDOG description)
Start up delay out of the HALT mode

The IDLE Timer T0 can generate an interrupt when the thirteenth bit toggles. This toggle is latched into the T0PND pending flag, and will occur every 4 ms at the maximum clock frequency ($t_c = 1 \mu s$). A control flag TOEN allows the interrupt from the thirteenth bit of Timer T0 to be enabled or disabled. Setting TOEN will enable the interrupt, while resetting it will disable the interrupt.

Timers (Continued)

TIMER T1, TIMER T2 AND TIMER T3

The devices have a set of three powerful timer/counter blocks, T1, T2 and T3. The associated features and functioning of a timer block are described by referring to the timer block Tx. Since the three timer blocks, T1, T2 and T3 are identical, all comments are equally applicable to any of the three timer blocks.

Each timer block consists of a 16-bit timer, Tx, and two supporting 16-bit autoreload/capture registers, RxA and RxB. Each timer block has two pins associated with it, TxA and TxB. The pin TxA supports I/O required by the timer block, while the pin TxB is an input to the timer block. The powerful and flexible timer block allows the device to easily perform all timer functions with minimal software overhead. The timer block has three operating modes: Processor Independent PWM mode, External Event Counter mode, and Input Capture mode.

The control bits TxC3, TxC2, and TxC1 allow selection of the different modes of operation.

Mode 1. Processor Independent PWM Mode

As the name suggests, this mode allows the device to generate a PWM signal with very minimal user intervention. The user only has to define the parameters of the PWM signal (ON time and OFF time). Once begun, the timer block will continuously generate the PWM signal completely independent of the microcontroller. The user software services the timer block only when the PWM parameters require updating.

In this mode the timer Tx counts down at a fixed rate of t_c . Upon every underflow the timer is alternately reloaded with the contents of supporting registers, RxA and RxB. The very first underflow of the timer causes the timer to reload from the register RxA. Subsequent underflows cause the timer to be reloaded from the registers alternately beginning with the register RxB.

The Tx Timer control bits, TxC3, TxC2 and TxC1 set up the timer for PWM mode operation.

Figure 7 shows a block diagram of the timer in PWM mode. The underflows can be programmed to toggle the TxA output pin. The underflows can also be programmed to generate interrupts.

Underflows from the timer are alternately latched into two pending flags, TxPNDA and TxPNDB. The user must reset these pending flags under software control. Two control enable flags, TxENA and TxENB, allow the interrupts from the timer underflow to be enabled or disabled. Setting the timer enable flag TxENA will cause an interrupt when a timer underflow causes the RxA register to be reloaded into the timer. Setting the timer enable flag TxENB will cause an interrupt when a timer underflow causes the RxB register to be reloaded into the timer. Resetting the timer enable flags will disable the associated interrupts.

Either or both of the timer underflow interrupts may be enabled. This gives the user the flexibility of interrupting once per PWM period on either the rising or falling edge of the PWM output. Alternatively, the user may choose to interrupt on both edges of the PWM output.

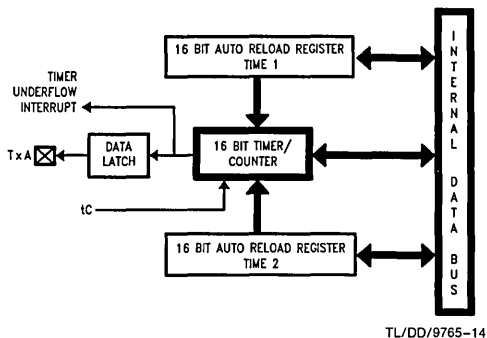

FIGURE 7. Timer in PWM Mode

Mode 2. External Event Counter Mode

This mode is quite similar to the processor independent PWM mode described above. The main difference is that the timer, Tx, is clocked by the input signal from the TxA pin. The Tx timer control bits, TxC3, TxC2 and TxC1 allow the timer to be clocked either on a positive or negative edge from the TxA pin. Underflows from the timer are latched into the TxPNDA pending flag. Setting the TxENA control flag will cause an interrupt when the timer underflows.

In this mode the input pin TxB can be used as an independent positive edge sensitive interrupt input if the TxENB control flag is set. The occurrence of a positive edge on the TxB input pin is latched into the TxPNDB flag.

Figure 8 shows a block diagram of the timer in External Event Counter mode.

Note: The PWM output is not available in this mode since the TxA pin is being used as the counter input clock.

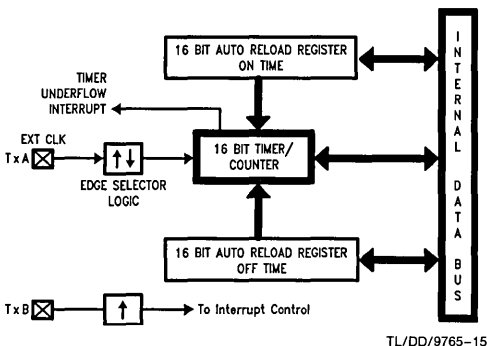

FIGURE 8. Timer in External Event Counter Mode

Mode 3. Input Capture Mode

The device can precisely measure external frequencies or time external events by placing the timer block, Tx, in the input capture mode.

In this mode, the timer Tx is constantly running at the fixed t_c rate. The two registers, RxA and RxB, act as capture registers. Each register acts in conjunction with a pin. The register RxA acts in conjunction with the TxA pin and the register RxB acts in conjunction with the TxB pin.

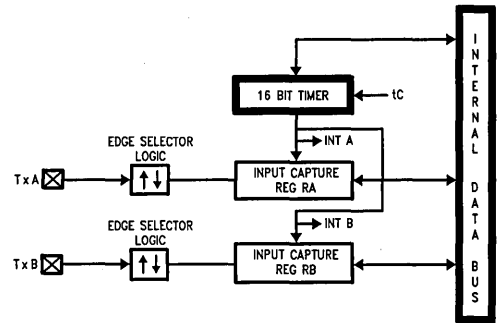

Timers (Continued)

The timer value gets copied over into the register when a trigger event occurs on its corresponding pin. Control bits, TxC3, TxC2 and TxC1, allow the trigger events to be specified either as a positive or a negative edge. The trigger condition for each input pin can be specified independently.

The trigger conditions can also be programmed to generate interrupts. The occurrence of the specified trigger condition on the TxA and TxB pins will be respectively latched into the pending flags, TxPNDA and TxPNDB. The control flag TxENA allows the interrupt on TxA to be either enabled or disabled. Setting the TxENA flag enables interrupts to be generated when the selected trigger condition occurs on the TxA pin. Similarly, the flag TxENB controls the interrupts from the TxB pin.

Underflows from the timer can also be programmed to generate interrupts. Underflows are latched into the timer TxCO pending flag (the TxCO control bit serves as the timer underflow interrupt pending flag in the Input Capture mode). Consequently, the TxCO control bit should be reset when entering the Input Capture mode. The timer underflow interrupt is generated when the selected trigger condition occurs on the TxA pin. When a TxA interrupt occurs in the Input Capture mode, the user must check both the TxPNDA and TxCO pending flags in order to determine whether a TxA input capture or a timer underflow (or both) caused the interrupt.

Figure 9 shows a block diagram of the timer in Input Capture mode.

TL/DD/9765-16

FIGURE 9. Timer In Input Capture Mode

TIMER CONTROL FLAGS

The timers T1, T2 and T3 have identical control structures. The control bits and their functions are summarized below.

TxC0	Timer Start/Stop control in Modes 1 and 2 (Processor Independent PWM and External Event Counter), where 1 = Start, 0 = Stop
TxC0	Timer Underflow Interrupt Pending Flag in Mode 3 (Input Capture)
TxPNDA	Timer Interrupt Pending Flag
TxPNDB	Timer Interrupt Pending Flag
TxENA	Timer Interrupt Enable Flag
TxENB	Timer Interrupt Enable Flag
	1 = Timer Interrupt Enabled
	0 = Timer Interrupt Disabled
TxC3	Timer mode control
TxC2	Timer mode control
TxC1	Timer mode control

Timers (Continued)

The timer mode control bits (TxC3, TxC2 and TxC1) are detailed below:

TxC3	TxC2	TxC1	Timer Mode	Interrupt A Source	Interrupt B Source	Timer Counts On
0	0	0	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Pos. Edge
0	0	1	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Neg. Edge
1	0	1	MODE 1 (PWM) TxA Toggle	Autoreload RA	Autoreload RB	t_c
1	0	0	MODE 1 (PWM) No TxA Toggle	Autoreload RA	Autoreload RB	t_c
0	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Pos. Edge	Pos. TxA Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Neg. Edge	Pos. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c
0	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Pos. Edge	Neg. TxB Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Neg. Edge	Neg. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c

Power Save Modes

The devices offer the user two power save modes of operation: HALT and IDLE. In the HALT mode, all microcontroller activities are stopped. In the IDLE mode, the on-board oscillator circuitry the WATCHDOG logic, the Clock Monitor and timer T0 are active but all other microcontroller activities are stopped. In either mode, all on-board RAM, registers, I/O states, and timers (with the exception of T0) are unaltered.

HALT MODE

The devices can be placed in the HALT mode by writing a "1" to the HALT flag (G7 data bit). All microcontroller activities, including the clock and timers, are stopped. The WATCHDOG logic on the device is disabled during the HALT mode. However, the clock monitor circuitry if enabled remains active and will cause the WATCHDOG output pin (WDOUT) to go low. If the HALT mode is used and the user does not want to activate the WDOUT pin, the Clock Monitor should be disabled after the device comes out of reset (resetting the Clock Monitor control bit with the first write to the WDSVR register). In the HALT mode, the power requirements of the device are minimal and the applied voltage (V_{CC}) may be decreased to V_f ($V_f = 2.0V$) without altering the state of the machine.

The devices support three different ways of exiting the HALT mode. The first method of exiting the HALT mode is with the Multi-Input Wakeup feature on the L port. The second method is with a low to high transition on the CKO (G7) pin. This method precludes the use of the crystal clock con-

figuration (since CKO becomes a dedicated output), and so may be used with an RC clock configuration. The third method of exiting the HALT mode is by pulling the RESET pin low.

Since a crystal or ceramic resonator may be selected as the oscillator, the Wakeup signal is not allowed to start the chip running immediately since crystal oscillators and ceramic resonators have a delayed start up time to reach full amplitude and frequency stability. The IDLE timer is used to generate a fixed delay to ensure that the oscillator has indeed stabilized before allowing instruction execution. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry is enabled. The IDLE timer is loaded with a value of 256 and is clocked with the t_c instruction cycle clock. The t_c clock is derived by dividing the oscillator clock down by a factor of 10. The Schmitt trigger following the CKI inverter on the chip ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If an RC clock option is being used, the fixed delay is introduced optionally. A control bit, CLKDLY, mapped as configuration bit G7, controls whether the delay is to be introduced or not. The delay is included if CLKDLY is set, and excluded if CLKDLY is reset. The CLKDLY bit is cleared on reset.

Power Save Modes (Continued)

The devices have two mask options associated with the HALT mode. The first mask option enables the HALT mode feature, while the second mask option disables the HALT mode. With the HALT mode enable mask option, the device will enter and exit the HALT mode as described above. With the HALT disable mask option, the device cannot be placed in the HALT mode (writing a "1" to the HALT flag will have no effect).

The WATCHDOG detector circuit is inhibited during the HALT mode. However, the clock monitor circuit if enabled remains active during HALT mode in order to ensure a clock monitor error if the device inadvertently enters the HALT mode as a result of a runaway program or power glitch.

IDLE MODE

The device is placed in the IDLE mode by writing a "1" to the IDLE flag (G6 data bit). In this mode, all activities, except the associated on-board oscillator circuitry, the WATCHDOG logic, the clock monitor and the IDLE Timer T0, are stopped. The power supply requirements of the microcontroller in this mode of operation are typically around 30% of normal power requirement of the microcontroller.

As with the HALT mode, the device can be returned to normal operation with a reset, or with a Multi-Input Wakeup from the L Port. Alternately, the microcontroller resumes normal operation from the IDLE mode when the thirteenth bit (representing 4.096 ms at internal clock frequency of 1 MHz, $t_c = 1 \mu\text{s}$) of the IDLE Timer T0 is reached.

This toggle condition of the thirteenth bit of the IDLE Timer T0 is latched into the TOPND pending flag.

The user has the option of being interrupted with a transition on the thirteenth bit of the IDLE Timer T0. The interrupt can be enabled or disabled via the T0EN control bit. Setting the T0EN flag enables the interrupt and vice versa.

The user can enter the IDLE mode with the Timer T0 interrupt enabled. In this case, when the TOPND bit gets set, the device will first execute the Timer T0 interrupt service routine and then return to the instruction following the "Enter Idle Mode" instruction.

Alternatively, the user can enter the IDLE mode with the IDLE Timer T0 interrupt disabled. In this case, the device will resume normal operation with the instruction immediately following the "Enter IDLE Mode" instruction.

Note: It is necessary to program two NOP instructions following both the set HALT mode and set IDLE mode instructions. These NOP instructions are necessary to allow clock resynchronization following the HALT or IDLE modes.

Multi-Input Wakeup

The Multi-Input Wakeup feature is used to return (wakeup) the device from either the HALT or IDLE modes. Alternately Multi-Input Wakeup/Interrupt feature may also be used to generate up to 8 edge selectable external interrupts.

Figure 10 shows the Multi-Input Wakeup logic for the COP888CG microcontroller.

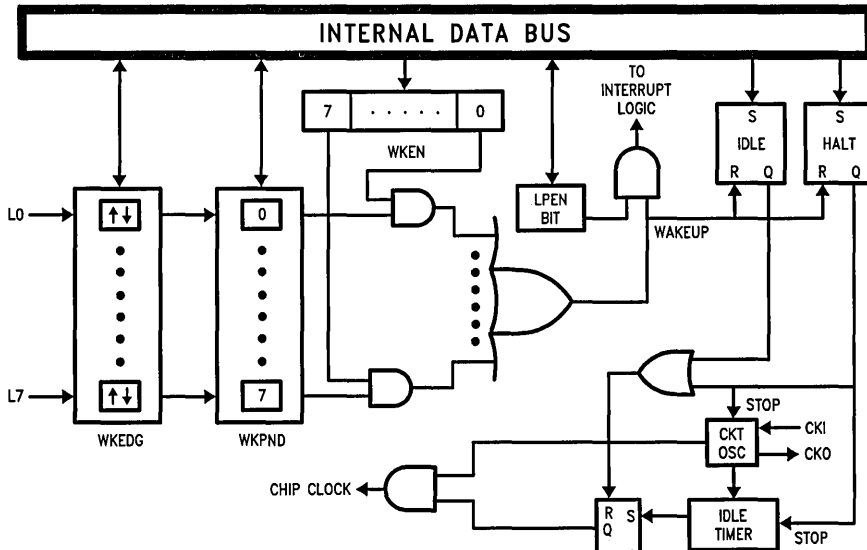

FIGURE 10. Multi-Input Wake Up Logic

TL/DD/9765-17

Multi-Input Wakeup (Continued)

The Multi-Input Wakeup feature utilizes the L Port. The user selects which particular L port bit (or combination of L Port bits) will cause the device to exit the HALT or IDLE modes. The selection is done through the Reg: WKEN. The Reg: WKEN is an 8-bit read/write register, which contains a control bit for every L port bit. Setting a particular WKEN bit enables a Wakeup from the associated L port pin.

The user can select whether the trigger condition on the selected L Port pin is going to be either a positive edge (low to high transition) or a negative edge (high to low transition). This selection is made via the Reg: WKEDG, which is an 8-bit control register with a bit assigned to each L Port pin. Setting the control bit will select the trigger condition to be a negative edge on that particular L Port pin. Resetting the bit selects the trigger condition to be a positive edge. Changing an edge select entails several steps in order to avoid a pseudo Wakeup condition as a result of the edge change. First, the associated WKEN bit should be reset, followed by the edge select change in WKEDG. Next, the associated WKPND bit should be cleared, followed by the associated WKEN bit being re-enabled.

An example may serve to clarify this procedure. Suppose we wish to change the edge select from positive (low going high) to negative (high going low) for L Port bit 5, where bit 5 has previously been enabled for an input interrupt. The program would be as follows:

```

RBIT 5, WKEN
SBIT 5, WKEDG
RBIT 5, WKPND
SBIT 5, WKEN

```

If the L port bits have been used as outputs and then changed to inputs with Multi-Input Wakeup/Interrupt, a safety procedure should also be followed to avoid inherited pseudo wakeup conditions. After the selected L port bits have been changed from output to input but before the associated WKEN bits are enabled, the associated edge select bits in WKEDG should be set or reset for the desired edge selects, followed by the associated WKPND bits being cleared.

This same procedure should be used following reset, since the L port inputs are left floating as a result of reset.

The occurrence of the selected trigger condition for Multi-Input Wakeup is latched into a pending register called WKPND. The respective bits of the WKPND register will be set on the occurrence of the selected trigger edge on the corresponding Port L pin. The user has the responsibility of clearing these pending flags. Since WKPND is a pending register for the occurrence of selected wakeup conditions, the device will not enter the HALT mode if any Wakeup bit is both enabled and pending. Consequently, the user has the responsibility of clearing the pending flags before attempting to enter the HALT mode.

WKEN, WKPND and WKEDG are all read/write registers, and are cleared at reset.

PORT L INTERRUPTS

Port L provides the user with an additional eight fully selectable, edge sensitive interrupts which are all vectored into the same service subroutine.

The interrupt from Port L shares logic with the wake up circuitry. The register WKEN allows interrupts from Port L to be individually enabled or disabled. The register WKEDG specifies the trigger condition to be either a positive or a negative edge. Finally, the register WKPND latches in the pending trigger conditions.

The GIE (Global Interrupt Enable) bit enables the interrupt function.

A control flag, LPEN, functions as a global interrupt enable for Port L interrupts. Setting the LPEN flag will enable interrupts and vice versa. A separate global pending flag is not needed since the register WKPND is adequate.

Since Port L is also used for waking the device out of the HALT or IDLE modes, the user can elect to exit the HALT or IDLE modes either with or without the interrupt enabled. If he elects to disable the interrupt, then the device will restart execution from the instruction immediately following the instruction that placed the microcontroller in the HALT or IDLE modes. In the other case, the device will first execute the interrupt service routine and then revert to normal operation.

The Wakeup signal will not start the chip running immediately since crystal oscillators or ceramic resonators have a finite start up time. The IDLE Timer (T₀) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the device to execute instructions. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry and the IDLE Timer T₀ are enabled. The IDLE Timer is loaded with a value of 256 and is clocked from the t_c instruction cycle clock. The t_c clock is derived by dividing down the oscillator clock by a factor of 10. A Schmitt trigger following the CKI on-chip inverter ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If the RC clock option is used, the fixed delay is under software control. A control flag, CLKDLY, in the G7 configuration bit allows the clock start up delay to be optionally inserted. Setting CLKDLY flag high will cause clock start up delay to be inserted and resetting it will exclude the clock start up delay. The CLKDLY flag is cleared during reset, so the clock start up delay is not present following reset with the RC clock options.

UART

The COP888CG contains a full-duplex software programmable UART. The UART (Figure 11) consists of a transmit shift register, a receiver shift register and seven addressable registers, as follows: a transmit buffer register (TBUF), a receiver buffer register (RBUF), a UART control and status register (ENU), a UART receive control and status register (ENUR), a UART interrupt and clock source register (ENUI), a prescaler select register (PSR) and baud (BAUD) register. The ENU register contains flags for transmit and receive functions; this register also determines the length of the data frame (7, 8 or 9 bits), the value of the ninth bit in transmission, and parity selection bits. The ENUR register flags framing, data overrun and parity errors while the UART is receiving.

Other functions of the ENUR register include saving the ninth bit received in the data frame, enabling or disabling the UART's attention mode of operation and providing additional receiver/transmitter status information via RCVG and XMTG bits. The determination of an internal or external clock source is done by the ENUI register, as well as selecting the number of stop bits and enabling or disabling transmit and receive interrupts. A control flag in this register can also select the UART mode of operation: asynchronous or synchronous.

FIGURE 11. UART Block Diagram

UART (Continued)

UART CONTROL AND STATUS REGISTERS

The operation of the UART is programmed through three registers: ENU, ENUR and ENUI. The function of the individual bits in these registers is as follows:

ENU-UART Control and Status Register (Address at 0BA)

PEN	PSEL1	XBIT9/ PSEL0	CHL1	CHL0	ERR	RBFL	TBMT
0RW	0RW	0RW	0RW	0RW	0R	0R	1R

Bit 7 Bit 0

ENUR-UART Receive Control and Status Register (Address at 0BB)

DOE	FE	PE	SPARE	RBIT9	ATTN	XMTG	RCVG
0RD	0RD	0RD	0RW*	0R	0RW	0R	0R

Bit7 Bit0

ENUI-UART Interrupt and Clock Source Register (Address at 0BC)

STP2	STP78	ETDX	SSEL	XRCLK	XTCLK	ERI	ETI
0RW	0RW	0RW	0RW	0RW	0RW	0RW	0RW

Bit7 Bit0

*Bit is not used.

- 0 Bit is cleared on reset.
- 1 Bit is set to one on reset.
- R Bit is read-only; it cannot be written by software.
- RW Bit is read/writes.
- D Bit is cleared on read; when read by software as a one, it is cleared automatically. Writing to the bit does not affect its state.

DESCRIPTION OF UART REGISTER BITS

ENU—UART CONTROL AND STATUS REGISTER

TBMT: This bit is set when the UART transfers a byte of data from the TBUF register into the TSFT register for transmission. It is automatically reset when software writes into the TBUF register.

RBFL: This bit is set when the UART has received a complete character and has copied it into the RBUF register. It is automatically reset when software reads the character from RBUF.

ERR: This bit is a global UART error flag which gets set if any or a combination of the errors (DOE, FE, PE) occur.

CHL1, CHL0: These bits select the character frame format. Parity is not included and is generated/verified by hardware.
 CHL1 = 0, CHL0 = 0 The frame contains eight data bits.
 CHL1 = 0, CHL0 = 1 The frame contains seven data bits.

CHL1 = 1, CHL0 = 0 The frame contains nine data bits.
 CHL1 = 1, CHL0 = 1 Loopback Mode selected. Transmitter output internally looped back to receiver input. Nine bit framing format is used.

XBIT9/PSEL0: Programs the ninth bit for transmission when the UART is operating with nine data bits per frame. For seven or eight data bits per frame, this bit in conjunction with PSEL1 selects parity.

PSEL1, PSEL0: Parity select bits.

- PSEL1 = 0, PSEL0 = 0 Odd Parity (if Parity enabled)
- PSEL1 = 0, PSEL0 = 1 Even Parity (if Parity enabled)

- PSEL1 = 1, PSEL0 = 0 Mark(1) (if Parity enabled)
- PSEL1 = 1, PSEL0 = 1 Space(0) (if Parity enabled)

PEN: This bit enables/disables Parity (7- and 8-bit modes only).
 PEN = 0 Parity disabled.
 PEN = 1 Parity enabled.

ENUR—UART RECEIVE CONTROL AND STATUS REGISTER

RCVG: This bit is set high whenever a framing error occurs and goes low when RDX goes high.

XMTG: This bit is set to indicate that the UART is transmitting. It gets reset at the end of the last frame (end of last Stop bit).

ATTN: ATTENTION Mode is enabled while this bit is set. This bit is cleared automatically on receiving a character with data bit nine set.

RBIT9: Contains the ninth data bit received when the UART is operating with nine data bits per frame.

SPARE: Reserved for future use.

PE: Flags a Parity Error.

- PE = 0 Indicates no Parity Error has been detected since the last time the ENUR register was read.
- PE = 1 Indicates the occurrence of a Parity Error.

FE: Flags a Framing Error.

- FE = 0 Indicates no Framing Error has been detected since the last time the ENUR register was read.
- FE = 1 Indicates the occurrence of a Framing Error.

DOE: Flags a Data Overrun Error.

- DOE = 0 Indicates no Data Overrun Error has been detected since the last time the ENUR register was read.
- DOE = 1 Indicates the occurrence of a Data Overrun Error.

ENUI—UART INTERRUPT AND CLOCK SOURCE REGISTER

ETI: This bit enables/disables interrupt from the transmitter section.

- ETI = 0 Interrupt from the transmitter is disabled.
- ETI = 1 Interrupt from the transmitter is enabled.

ERI: This bit enables/disables interrupt from the receiver section.

- ERI = 0 Interrupt from the receiver is disabled.
- ERI = 1 Interrupt from the receiver is enabled.

XTCLK: This bit selects the clock source for the transmitter-section.

- XTCLK = 0 The clock source is selected through the PSR and BAUD registers.
- XTCLK = 1 Signal on CKX (L1) pin is used as the clock.

XRCLK: This bit selects the clock source for the receiver section.

- XRCLK = 0 The clock source is selected through the PSR and BAUD registers.
- XRCLK = 1 Signal on CKX (L1) pin is used as the clock.

SSEL: UART mode select.

- SSEL = 0 Asynchronous Mode.
- SSEL = 1 Synchronous Mode.

UART (Continued)

ETDX: TDX (UART Transmit Pin) is the alternate function assigned to Port L pin L2; it is selected by setting ETDX bit. To simulate line break generation, software should reset ETDX bit and output logic zero to TDX pin through Port L data and configuration registers.

STP78: This bit is set to program the last Stop bit to be 7/8th of a bit in length.

STP2: This bit programs the number of Stop bits to be transmitted.

STP2 = 0 One Stop bit transmitted.

STP2 = 1 Two Stop bits transmitted.

Associated I/O Pins

Data is transmitted on the TDX pin and received on the RDX pin. TDX is the alternate function assigned to Port L pin L2; it is selected by setting ETDX (in the ENUI register) to one. RDX is an inherent function of Port L pin L3, requiring no setup.

The baud rate clock for the UART can be generated on-chip, or can be taken from an external source. Port L pin L1 (CKX) is the external clock I/O pin. The CKX pin can be either an input or an output, as determined by Port L Configuration and Data registers (Bit 1). As an input, it accepts a clock signal which may be selected to drive the transmitter and/or receiver. As an output, it presents the internal Baud Rate Generator output.

UART Operation

The UART has two modes of operation: asynchronous mode and synchronous mode.

ASYNCHRONOUS MODE

This mode is selected by resetting the SSEL (in the ENUI register) bit to zero. The input frequency to the UART is 16 times the baud rate.

The TSFT and TBUF registers double-buffer data for transmission. While TSFT is shifting out the current character on the TDX pin, the TBUF register may be loaded by software with the next byte to be transmitted. When TSFT finishes transmitting the current character the contents of TBUF are transferred to the TSFT register and the Transmit Buffer Empty Flag (TBMT in the ENU register) is set. The TBMT flag is automatically reset by the UART when software loads a new character into the TBUF register. There is also the XMTG bit which is set to indicate that the UART is transmitting. This bit gets reset at the end of the last frame (end of last Stop bit). TBUF is a read/write register.

The RSFT and RBUF registers double-buffer data being received. The UART receiver continually monitors the signal on the RDX pin for a low level to detect the beginning of a Start bit. Upon sensing this low level, it waits for half a bit time and samples again. If the RDX pin is still low, the receiver considers this to be a valid Start bit, and the remaining bits in the character frame are each sampled a single time, at the mid-bit position. Serial data input on the RDX pin is shifted into the RSFT register. Upon receiving the complete character, the contents of the RSFT register are copied into the RBUF register and the Received Buffer Full Flag (RBFL) is set. RBFL is automatically reset when software reads the character from the RBUF register. RBUF is a read only register. There is also the RCVG bit which is set high

when a framing error occurs and goes low once RDX goes high. TBMT, XMTG, RBFL and RCVG are read only bits.

SYNCHRONOUS MODE

In this mode data is transferred synchronously with the clock. Data is transmitted on the rising edge and received on the falling edge of the synchronous clock.

This mode is selected by setting SSEL bit in the ENUI register. The input frequency to the UART is the same as the baud rate.

When an external clock input is selected at the CKX pin, data transmit and receive are performed synchronously with this clock through TDX/RDX pins.

If data transmit and receive are selected with the CKX pin as clock output, the device generates the synchronous clock output at the CKX pin. The internal baud rate generator is used to produce the synchronous clock. Data transmit and receive are performed synchronously with this clock.

FRAMING FORMATS

The UART supports several serial framing formats (*Figure 12*). The format is selected using control bits in the ENU, ENUR and ENUI registers.

The first format (1, 1a, 1b, 1c) for data transmission (CHL0 = 1, CHL1 = 0) consists of Start bit, seven Data bits (excluding parity) and 7/8, one or two Stop bits. In applications using parity, the parity bit is generated and verified by hardware.

The second format (CHL0 = 0, CHL1 = 0) consists of one Start bit, eight Data bits (excluding parity) and 7/8, one or two Stop bits. Parity bit is generated and verified by hardware.

The third format for transmission (CHL0 = 0, CHL1 = 1) consists of one Start bit, nine Data bits and 7/8, one or two Stop bits. This format also supports the UART "ATTENTION" feature. When operating in this format, all eight bits of TBUF and RBUF are used for data. The ninth data bit is transmitted and received using two bits in the ENU and ENUR registers, called XBIT9 and RBIT9. RBIT9 is a read only bit. Parity is not generated or verified in this mode.

For any of the above framing formats, the last Stop bit can be programmed to be 7/8th of a bit in length. If two Stop bits are selected and the 7/8th bit is set (selected), the second Stop bit will be 7/8th of a bit in length.

The parity is enabled/disabled by PEN bit located in the ENU register. Parity is selected for 7- and 8-bit modes only. If parity is enabled (PEN = 1), the parity selection is then performed by PSEL0 and PSEL1 bits located in the ENU register.

Note that the XBIT9/PSEL0 bit located in the ENU register serves two mutually exclusive functions. This bit programs the ninth bit for transmission when the UART is operating with nine data bits per frame. There is no parity selection in this framing format. For other framing formats XBIT9 is not needed and the bit is PSEL0 used in conjunction with PSEL1 to select parity.

The frame formats for the receiver differ from the transmitter in the number of Stop bits required. The receiver only requires one Stop bit in a frame, regardless of the setting of the Stop bit selection bits in the control register. Note that an implicit assumption is made for full duplex UART operation that the framing formats are the same for the transmitter and receiver.

UART Operation (Continued)

TL/DD/9765-19

FIGURE 12. Framing Formats

UART INTERRUPTS

The UART is capable of generating interrupts. Interrupts are generated on Receive Buffer Full and Transmit Buffer Empty. Both interrupts have individual interrupt vectors. Two bytes of program memory space are reserved for each interrupt vector. The two vectors are located at addresses 0xEC to 0xEF Hex in the program memory space. The interrupts can be individually enabled or disabled using Enable Transmit Interrupt (ETI) and Enable Receive Interrupt (ERI) bits in the ENUI register.

The interrupt from the Transmitter is set pending, and remains pending, as long as both the TBMT and ETI bits are set. To remove this interrupt, software must either clear the ETI bit or write to the TBUF register (thus clearing the TBMT bit).

The interrupt from the receiver is set pending, and remains pending, as long as both the RBFL and ERI bits are set. To remove this interrupt, software must either clear the ERI bit or read from the RBUF register (thus clearing the RBFL bit).

Baud Clock Generation

The clock inputs to the transmitter and receiver sections of the UART can be individually selected to come either from an external source at the CKX pin (port L, pin L1) or from a

source selected in the PSR and BAUD registers. Internally, the basic baud clock is created from the oscillator frequency through a two-stage divider chain consisting of a 1-16 (increments of 0.5) prescaler and an 11-bit binary counter. (Figure 13) The divide factors are specified through two read/write registers shown in Figure 14. Note that the 11-bit Baud Rate Divisor spills over into the Prescaler Select Register (PSR). PSR is cleared upon reset.

As shown in Table I, a Prescaler Factor of 0 corresponds to NO CLOCK. NO CLOCK condition is the UART power down mode where the UART clock is turned off for power saving purpose. The user must also turn the UART clock off when a different baud rate is chosen.

The correspondences between the 5-bit Prescaler Select and Prescaler factors are shown in Table I. There are many ways to calculate the two divisor factors, but one particularly effective method would be to achieve a 1.8432 MHz frequency coming out of the first stage. The 1.8432 MHz prescaler output is then used to drive the software programmable baud rate counter to create a x16 clock for the following baud rates: 110, 134.5, 150, 300, 600, 1200, 1800, 2400, 3600, 4800, 7200, 9600, 19200 and 38400 (Table II). Other baud rates may be created by using appropriate divisors. The x16 clock is then divided by 16 to provide the rate for the serial shift registers of the transmitter and receiver.

Baud Clock Generation (Continued)

11101	15
11110	15.5
11111	16

TABLE II. Baud Rate Divisors (1.8432 MHz Prescaler Output)

Baud Rate	Baud Rate Divisor - 1 (N-1)
110 (110.03)	1046
134.5 (134.58)	855
150	767
300	383
600	191
1200	95
1800	63
2400	47
3600	31
4800	23
7200	15
9600	11
19200	5
38400	2

The entries in Table II assume a prescaler output of 1.8432 MHz. In the asynchronous mode the baud rate could be as high as 625k.

As an example, considering the Asynchronous Mode and a CKI clock of 4.608 MHz, the prescaler factor selected is:

$$4.608 / 1.8432 = 2.5$$

The 2.5 entry is available in Table I. The 1.8432 MHz prescaler output is then used with proper Baud Rate Divisor (Table II) to obtain different baud rates. For a baud rate of 19200 e.g., the entry in Table II is 5.

$$N - 1 = 5 \quad (N - 1 \text{ is the value from Table II})$$

$$N = 6 \quad (N \text{ is the Baud Rate Divisor})$$

$$\text{Baud Rate} = 1.8432 \text{ MHz} / (16 \times 6) = 19200$$

The divide by 16 is performed because in the asynchronous mode, the input frequency to the UART is 16 times the baud rate. The equation to calculate baud rates is given below.

The actual Baud Rate may be found from:

$$BR = Fc / (16 \times N \times P)$$

Baud Clock Generation (Continued)

Where:

BR is the Baud Rate

F_c is the CKI frequency

N is the Baud Rate Divisor (Table II).

P is the Prescaler Divide Factor selected by the value in the Prescaler Select Register (Table I)

Note: In the Synchronous Mode, the divisor 16 is replaced by two.

Example:

Asynchronous Mode:

$$\text{Crystal Frequency} = 5 \text{ MHz}$$

$$\text{Desired baud rate} = 9600$$

Using the above equation $N \times P$ can be calculated first.

$$N \times P = (5 \times 10^6) / (16 \times 9600) = 32.552$$

Now 32.552 is divided by each Prescaler Factor (Table II) to obtain a value closest to an integer. This factor happens to be 6.5 (P = 6.5).

$$N = 32.552 / 6.5 = 5.008 \quad (N = 5)$$

The programmed value (from Table II) should be 4 (N - 1).

Using the above values calculated for N and P:

$$\text{BR} = (5 \times 10^6) / (16 \times 5 \times 6.5) = 9615.384$$

$$\% \text{ error} = (9615.385 - 9600) / 9600 = 0.16$$

Effect of HALT/IDLE

The UART logic is reinitialized when either the HALT or IDLE modes are entered. This reinitialization sets the TBMT flag and resets all read only bits in the UART control and status registers. Read/Write bits remain unchanged. The Transmit Buffer (TBUF) is not affected, but the Transmit Shift register (TSFT) bits are set to one. The receiver registers RBUF and RSFT are not affected.

The device will exit from the HALT/IDLE modes when the Start bit of a character is detected at the RDX (L3) pin. This feature is obtained by using the Multi-Input Wakeup scheme provided on the device.

Before entering the HALT or IDLE modes the user program must select the Wakeup source to be on the RDX pin. This selection is done by setting bit 3 of WKEN (Wakeup Enable) register. The Wakeup trigger condition is then selected to be high to low transition. This is done via the WKEDG register (Bit 3 is zero.)

If the device is halted and crystal oscillator is used, the Wakeup signal will not start the chip running immediately because of the finite start up time requirement of the crystal oscillator. The idle timer (T0) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the device to execute code. The user has to consider this delay when data transfer is expected immediately after exiting the HALT mode.

Diagnostic

Bits CHARL0 and CHARL1 in the ENU register provide a loopback feature for diagnostic testing of the UART. When these bits are set to one, the following occur: The receiver input pin (RDX) is internally connected to the transmitter output pin (TDX); the output of the Transmitter Shift Register is "looped back" into the Receive Shift Register input. In this mode, data that is transmitted is immediately received. This feature allows the processor to verify the transmit and receive data paths of the UART.

Note that the framing format for this mode is the nine bit format; one Start bit, nine data bits, and 7/8, one or two Stop bits. Parity is not generated or verified in this mode.

Attention Mode

The UART Receiver section supports an alternate mode of operation, referred to as ATTENTION Mode. This mode of operation is selected by the ATTN bit in the ENUR register. The data format for transmission must also be selected as having nine Data bits and either 7/8, one or two Stop bits.

The ATTENTION mode of operation is intended for use in networking the device with other processors. Typically in such environments the messages consists of device addresses, indicating which of several destinations should receive them, and the actual data. This Mode supports a scheme in which addresses are flagged by having the ninth bit of the data field set to a 1. If the ninth bit is reset to a zero the byte is a Data byte.

While in ATTENTION mode, the UART monitors the communication flow, but ignores all characters until an address character is received. Upon receiving an address character, the UART signals that the character is ready by setting the RBFL flag, which in turn interrupts the processor if UART Receiver interrupts are enabled. The ATTN bit is also cleared automatically at this point, so that data characters as well as address characters are recognized. Software examines the contents of the RBUF and responds by deciding either to accept the subsequent data stream (by leaving the ATTN bit reset) or to wait until the next address character is seen (by setting the ATTN bit again).

Operation of the UART Transmitter is not affected by selection of this Mode. The value of the ninth bit to be transmitted is programmed by setting XBIT9 appropriately. The value of the ninth bit received is obtained by reading RBIT9. Since this bit is located in ENUR register where the error flags reside, a bit operation on it will reset the error flags.

Comparators

The devices contain two differential comparators, each with a pair of inputs (positive and negative) and an output. Ports I1-I3 and I4-I6 are used for the comparators. The following is the Port I assignment:

- I1 Comparator1 negative input
- I2 Comparator1 positive input
- I3 Comparator1 output
- I4 Comparator2 negative input
- I5 Comparator2 positive input
- I6 Comparator2 output

A Comparator Select Register (CMPSL) is used to enable the comparators, read the outputs of the comparators internally, and enable the outputs of the comparators to the pins. Two control bits (enable and output enable) and one result bit are associated with each comparator. The comparator result bits (CMP1RD and CMP2RD) are read only bits which will read as zero if the associated comparator is not enabled. The Comparator Select Register is cleared with reset, resulting in the comparators being disabled. The comparators should also be disabled before entering either the HALT or IDLE modes in order to save power. The configuration of the CMPSL register is as follows:

Comparators (Continued)

CMPSL REGISTER (ADDRESS X'00B7)

The CMPSL register contains the following bits:

- CMP1EN Enable comparator 1
- CMP1RD Comparator 1 result (this is a read only bit, which will read as 0 if the comparator is not enabled)
- CMP10E Selects pin 13 as comparator 1 output provided that CMP1EN is set to enable the comparator
- CMP2EN Enable comparator 2
- CMP2RD Comparator 2 result (this is a read only bit, which will read as 0 if the comparator is not enabled)
- CMP20E Selects pin 16 as comparator 2 output provided that CMP2EN is set to enable the comparator

Unused	CMP20E	CMP2RD	CMP2EN	CMP10E	CMP1RD	CMP1EN	Unused
Bit 7							Bit 0

Note that the two unused bits of CMPSL may be used as software flags.

Comparator outputs have the same spec as Ports L and G except that the rise and fall times are symmetrical.

Interrupts

The devices support a vectored interrupt scheme. It supports a total of fourteen interrupt sources. The following table lists all the possible device interrupt sources, their arbitration ranking and the memory locations reserved for the interrupt vector for each source.

Two bytes of program memory space are reserved for each interrupt source. All interrupt sources except the software interrupt are maskable. Each of the maskable interrupts have an Enable bit and a Pending bit. A maskable interrupt is active if its associated enable and pending bits are set. If GIE = 1 and an interrupt is active, then the processor will be interrupted as soon as it is ready to start executing an instruction except if the above conditions happen during the Software Trap service routine. This exception is described in the Software Trap sub-section.

The interruption process is accomplished with the INTR instruction (opcode 00), which is jammed inside the Instruction Register and replaces the opcode about to be executed. The following steps are performed for every interrupt:

1. The GIE (Global Interrupt Enable) bit is reset.
2. The address of the instruction about to be executed is pushed into the stack.
3. The PC (Program Counter) branches to address 00FF. This procedure takes 7 t_c cycles to execute.

FIGURE 15. Interrupt Block Diagram

TL/DD/9765-22

Interrupts (Continued)

Arbitration Ranking	Source	Description	Vector Address Hi-Low Byte
(1) Highest	Software	INTR Instruction	0yFE–0yFF
	Reserved	for Future Use	0yFC–0yFD
(2)	External	Pin G0 Edge	0yFA–0yFB
(3)	Timer T0	Underflow	0yF8–0yF9
(4)	Timer T1	T1A/Underflow	0yF6–0yF7
(5)	Timer T1	T1B	0yF4–0yF5
(6)	MICROWIRE/PLUS	BUSY Goes Low	0yF2–0yF3
	Reserved	for Future Use	0yF0–0yF1
(7)	UART	Receive	0yEE–0yEF
(8)	UART	Transmit	0yEC–0yED
(9)	Timer T2	T2A/Underflow	0yEA–0yEB
(10)	Timer T2	T2B	0yE8–0yE9
(11)	Timer T3	T3A/Underflow	0yE6–0yE7
(12)	Timer T3	T3B	0yE4–0yE5
(13)	Port L/Wakeup	Port L Edge	0yE2–0yE3
(14) Lowest	Default	VIS Instr. Execution without Any Interrupts	0yE0–0yE1

y is VIS page, y ≠ 0.

At this time, since GIE = 0, other maskable interrupts are disabled. The user is now free to do whatever context switching is required by saving the context of the machine in the stack with PUSH instructions. The user would then program a VIS (Vector Interrupt Select) instruction in order to branch to the interrupt service routine of the highest priority interrupt enabled and pending at the time of the VIS. Note that this is not necessarily the interrupt that caused the branch to address location 00FF Hex prior to the context switching.

Thus, if an interrupt with a higher rank than the one which caused the interruption becomes active before the decision of which interrupt to service is made by the VIS, then the interrupt with the higher rank will override any lower ones and will be acknowledged. The lower priority interrupt(s) are still pending, however, and will cause another interrupt immediately following the completion of the interrupt service routine associated with the higher priority interrupt just serviced. This lower priority interrupt will occur immediately following the RETI (Return from Interrupt) instruction at the end of the interrupt service routine just completed.

Inside the interrupt service routine, the associated pending bit has to be cleared by software. The RETI (Return from Interrupt) instruction at the end of the interrupt service routine will set the GIE (Global Interrupt Enable) bit, allowing the processor to be interrupted again if another interrupt is active and pending.

The VIS instruction looks at all the active interrupts at the time it is executed and performs an indirect jump to the beginning of the service routine of the one with the highest rank.

The addresses of the different interrupt service routines, called vectors, are chosen by the user and stored in ROM in a table starting at 01E0 (assuming that VIS is located between 00FF and 01DF). The vectors are 15-bit wide and therefore occupy 2 ROM locations.

VIS and the vector table must be located in the same 256-byte block (0y00 to 0yFF) except if VIS is located at the last address of a block. In this case, the table must be in the next block. The vector table cannot be inserted in the first 256-byte block (y ≠ 0).

The vector of the maskable interrupt with the lowest rank is located at 0yE0 (Hi-Order byte) and 0yE1 (Lo-Order byte) and so forth in increasing rank number. The vector of the maskable interrupt with the highest rank is located at 0yFA (Hi-Order byte) and 0yFB (Lo-Order byte).

The Software Trap has the highest rank and its vector is located at 0yFE and 0yFF.

If, by accident, a VIS gets executed and no interrupt is active, then the PC (Program Counter) will branch to a vector located at 0yE0–0yE1. This vector can point to the Software Trap (ST) interrupt service routine, or to another special service routine as desired.

Figure 15 shows the Interrupt block diagram.

SOFTWARE TRAP

The Software Trap (ST) is a special kind of non-maskable interrupt which occurs when the INTR instruction (used to acknowledge interrupts) is fetched from ROM and placed inside the instruction register. This may happen when the PC is pointing beyond the available ROM address space or when the stack is over-popped.

Interrupts (Continued)

When an ST occurs, the user can re-initialize the stack pointer and do a recovery procedure (similar to reset, but not necessarily containing all of the same initialization procedures) before restarting.

The occurrence of an ST is latched into the ST pending bit. The GIE bit is not affected and the ST pending bit (**not accessible by the user**) is used to inhibit other interrupts and to direct the program to the ST service routine with the VIS instruction. The RPND instruction is used to clear the software interrupt pending bit. This pending bit is also cleared on reset.

The ST has the highest rank among all interrupts.

Nothing (except another ST) can interrupt an ST being serviced.

WATCHDOG

The devices contain a WATCHDOG and clock monitor. The WATCHDOG is designed to detect the user program getting stuck in infinite loops resulting in loss of program control or "runaway" programs. The Clock Monitor is used to detect the absence of a clock or a very slow clock below a specified rate on the CKI pin.

The WATCHDOG consists of two independent logic blocks: WD UPPER and WD LOWER. WD UPPER establishes the upper limit on the service window and WD LOWER defines the lower limit of the service window.

Servicing the WATCHDOG consists of writing a specific value to a WATCHDOG Service Register named WDSVR which is memory mapped in the RAM. This value is composed of three fields, consisting of a 2-bit Window Select, a 5-bit Key Data field, and the 1-bit Clock Monitor Select field. Table III shows the WDSVR register.

The lower limit of the service window is fixed at 2048 instruction cycles. Bits 7 and 6 of the WDSVR register allow the user to pick an upper limit of the service window.

Table IV shows the four possible combinations of lower and upper limits for the WATCHDOG service window. This flexibility in choosing the WATCHDOG service window prevents any undue burden on the user software.

Bits 5, 4, 3, 2 and 1 of the WDSVR register represent the 5-bit Key Data field. The key data is fixed at 01100. Bit 0 of the WDSVR Register is the Clock Monitor Select bit.

TABLE III. WATCHDOG Service Register (WDSVR)

Window Select		Key Data					Clock Monitor
X	X	0	1	1	0	0	Y
7	6	5	4	3	2	1	0

TABLE IV. WATCHDOG Service Window Select

WDSVR Bit 7	WDSVR Bit 6	Service Window (Lower-Upper Limits)
0	0	2k–8k t_c Cycles
0	1	2k–16k t_c Cycles
1	0	2k–32k t_c Cycles
1	1	2k–64k t_c Cycles

Clock Monitor

The Clock Monitor aboard the device can be selected or deselected under program control. The Clock Monitor is guaranteed not to reject the clock if the instruction cycle clock ($1/t_c$) is greater or equal to 10 kHz. This equates to a clock input rate on CKI of greater or equal to 100 kHz.

WATCHDOG Operation

The WATCHDOG and Clock Monitor are disabled during reset. The device comes out of reset with the WATCHDOG armed, the WATCHDOG Window Select bits (bits 6, 7 of the WDSVR Register) set, and the Clock Monitor bit (bit 0 of the WDSVR Register) enabled. Thus, a Clock Monitor error will occur after coming out of reset, if the instruction cycle clock frequency has not reached a minimum specified value, including the case where the oscillator fails to start.

The WDSVR register can be written to only once after reset and the key data (bits 5 through 1 of the WDSVR Register) must match to be a valid write. This write to the WDSVR register involves two irrevocable choices: (i) the selection of the WATCHDOG service window (ii) enabling or disabling of the Clock Monitor. Hence, the first write to WDSVR Register involves selecting or deselecting the Clock Monitor, select the WATCHDOG service window and match the WATCHDOG key data. Subsequent writes to the WDSVR register will compare the value being written by the user to the WATCHDOG service window value and the key data (bits 7 through 1) in the WDSVR Register. Table V shows the sequence of events that can occur.

The user must service the WATCHDOG at least once before the upper limit of the service window expires. The WATCHDOG may not be serviced more than once in every lower limit of the service window. The user may service the WATCHDOG as many times as wished in the time period between the lower and upper limits of the service window. The first write to the WDSVR Register is also counted as a WATCHDOG service.

The WATCHDOG has an output pin associated with it. This is the WDOUT pin, on pin 1 of the port G. WDOUT is active low. The WDOUT pin is in the high impedance state in the inactive state. Upon triggering the WATCHDOG, the logic will pull the WDOUT (G1) pin low for an additional $16 t_c - 32 t_c$ cycles after the signal level on WDOUT pin goes below the lower Schmitt trigger threshold. After this delay, the device will stop forcing the WDOUT output low.

The WATCHDOG service window will restart when the WDOUT pin goes high. It is recommended that the user tie the WDOUT pin back to V_{CC} through a resistor in order to pull WDOUT high.

A WATCHDOG service while the WDOUT signal is active will be ignored. The state of the WDOUT pin is not guaranteed on reset, but if it powers up low then the WATCHDOG will time out and WDOUT will enter high impedance state.

The Clock Monitor forces the G1 pin low upon detecting a clock frequency error. The Clock Monitor error will continue until the clock frequency has reached the minimum specified value, after which the G1 output will enter the high impedance TRI-STATE mode following $16 t_c - 32 t_c$ clock cycles. The Clock Monitor generates a continual Clock Monitor error if the oscillator fails to start, or fails to reach the minimum specified frequency. The specification for the Clock Monitor is as follows:

$1/t_c > 10 \text{ kHz}$ —No clock rejection.

$1/t_c < 10 \text{ Hz}$ —Guaranteed clock rejection.

Watchdog and Clock Monitor Summary

The following salient points regarding the COP888CG WATCHDOG and CLOCK MONITOR should be noted:

- Both the WATCHDOG and CLOCK MONITOR detector circuits are inhibited during RESET.
- Following RESET, the WATCHDOG and CLOCK MONITOR are both enabled, with the WATCHDOG having the maximum service window selected.
- The WATCHDOG service window and CLOCK MONITOR enable/disable option can only be changed once, during the initial WATCHDOG service following RESET.
- The initial WATCHDOG service must match the key data value in the WATCHDOG Service register WDSVR in order to avoid a WATCHDOG error.
- Subsequent WATCHDOG services must match all three data fields in WDSVR in order to avoid WATCHDOG errors.
- The correct key data value cannot be read from the WATCHDOG Service register WDSVR. Any attempt to read this key data value of 01100 from WDSVR will read as key data value of all 0's.
- The WATCHDOG detector circuit is inhibited during both the HALT and IDLE modes.
- The CLOCK MONITOR detector circuit is active during both the HALT and IDLE modes. Consequently, the COP888 inadvertently entering the HALT mode will be detected as a CLOCK MONITOR error (provided that the CLOCK MONITOR enable option has been selected by the program).
- With the single-pin R/C oscillator mask option selected and the CLKDLY bit reset, the WATCHDOG service window will resume following HALT mode from where it left off before entering the HALT mode.
- With the crystal oscillator mask option selected, or with the single-pin R/C oscillator mask option selected and the CLKDLY bit set, the WATCHDOG service window will be set to its selected value from WDSVR following HALT. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following HALT, but must be serviced within the selected window to avoid a WATCHDOG error.
- The IDLE timer T0 is not initialized with RESET.
- The user can sync in to the IDLE counter cycle with an IDLE counter (T0) interrupt or by monitoring the TOPND flag. The TOPND flag is set whenever the thirteenth bit of the IDLE counter toggles (every 4096 instruction cycles). The user is responsible for resetting the TOPND flag.
- A hardware WATCHDOG service occurs just as the device exits the IDLE mode. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following IDLE, but must be serviced within the selected window to avoid a WATCHDOG error.
- Following RESET, the initial WATCHDOG service (where the service window and the CLOCK MONITOR enable/disable must be selected) may be programmed anywhere within the maximum service window (65,536 instruction cycles) initialized by RESET. Note that this initial WATCHDOG service may be programmed within the initial 2048 instruction cycles without causing a WATCHDOG error.

Detection of Illegal Conditions

The device can detect various illegal conditions resulting from coding errors, transient noise, power supply voltage drops, runaway programs, etc.

Reading of undefined ROM gets zeros. The opcode for software interrupt is zero. If the program fetches instructions from undefined ROM, this will force a software interrupt, thus signaling that an illegal condition has occurred.

The subroutine stack grows down for each call (jump to subroutine), interrupt, or PUSH, and grows up for each return or POP. The stack pointer is initialized to RAM location 06F Hex during reset. Consequently, if there are more returns than calls, the stack pointer will point to addresses 070 and 071 Hex (which are undefined RAM). Undefined RAM from addresses 070 to 07F (Segment 0), 140 to 17F (Segment 1), and all other segments (i.e., Segments 3 . . . etc.) is read as all 1's, which in turn will cause the program to return to address 7FFF Hex. This is an undefined ROM location and the instruction fetched (all 0's) from this location will generate a software interrupt signaling an illegal condition.

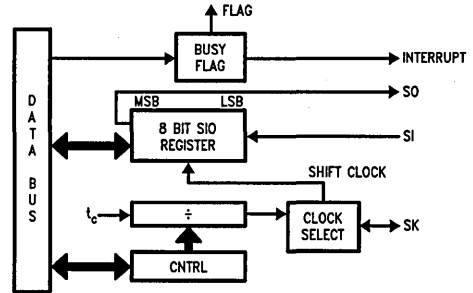

Thus, the chip can detect the following illegal conditions:

- Executing from undefined ROM
- Over "POP"ing the stack by having more returns than calls.

When the software interrupt occurs, the user can re-initialize the stack pointer and do a recovery procedure before re-starting (this recovery program is probably similar to that following reset, but might not contain the same program initialization procedures). The recovery program should reset the software interrupt pending bit using the RPND instruction.

MICROWIRE/PLUS

MICROWIRE/PLUS is a serial synchronous communications interface. The MICROWIRE/PLUS capability enables the device to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, E²PROMs etc.) and with other microcontrollers which support the MICROWIRE interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 12 shows a block diagram of the MICROWIRE/PLUS logic.

TL/DD/9765-23

FIGURE 16. MICROWIRE/PLUS Block Diagram

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS arrangement with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE/PLUS arrangement with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. In the master mode, the SK clock rate is selected by the two bits, SL0 and SL1, in the CNTRL register. Table VI details the different clock rates that may be selected.

TABLE V. WATCHDOG Service Actions

Key Data	Window Data	Clock Monitor	Action
Match	Match	Match	Valid Service: Restart Service Window
Don't Care	Mismatch	Don't Care	Error: Generate WATCHDOG Output
Mismatch	Don't Care	Don't Care	Error: Generate WATCHDOG Output

0	1	$4 \times t_c$
1	x	$8 \times t_c$

Where t_c is the instruction cycle clock

MICROWIRE/PLUS (Continued)

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. If enabled, an interrupt is generated when eight data bits have been shifted. The device may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. *Figure 13* shows how two devices, microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangements.

Warning:

The SIO register should only be loaded when the SK clock is low. Loading the SIO register while the SK clock is high will result in undefined data in the SIO register. SK clock is normally low when not shifting.

Setting the BUSY flag when the input SK clock is high in the MICROWIRE/PLUS slave mode may cause the current SK clock for the SIO shift register to be narrow. For safety, the BUSY flag should only be set when the input SK clock is low.

MICROWIRE/PLUS Master Mode Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the device. The MICROWIRE Master always initiates all data exchanges. The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table VII summarizes the bit settings required for Master mode of operation.

MICROWIRE/PLUS Slave Mode Operation

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by setting and resetting the appropriate bit in the Port G configuration register. Table VII summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated.

Alternate SK Phase Operation

The device allows either the normal SK clock or an alternate phase SK clock to shift data in and out of the SIO register. In both the modes the SK is normally low. In the normal mode data is shifted in on the rising edge of the SK clock and the data is shifted out on the falling edge of the SK clock. The SIO register is shifted on each falling edge of the SK clock. In the alternate SK phase operation, data is shifted in on the falling edge of the SK clock and shifted out on the rising edge of the SK clock.

A control flag, SKSEL, allows either the normal SK clock or the alternate SK clock to be selected. Resetting SKSEL causes the MICROWIRE/PLUS logic to be clocked from the normal SK signal. Setting the SKSEL flag selects the alternate SK clock. The SKSEL is mapped into the G6 configuration bit. The SKSEL flag will power up in the reset condition, selecting the normal SK signal.

TABLE VII

This table assumes that the control flag MSEL is set.

G4 (SO) Config. Bit	G5 (SK) Config. Bit	G4 Fun.	G5 Fun.	Operation
1	1	SO	Int. SK	MICROWIRE/PLUS Master
0	1	TRI-STATE	Int. SK	MICROWIRE/PLUS Master
1	0	SO	Ext. SK	MICROWIRE/PLUS Slave
0	0	TRI-STATE	Ext. SK	MICROWIRE/PLUS Slave

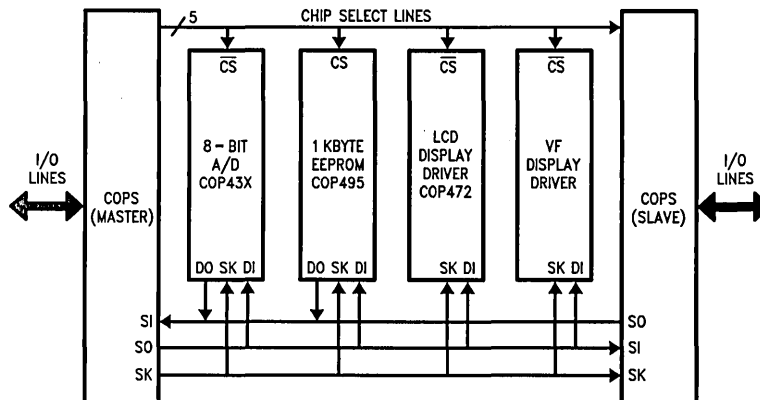

FIGURE 17. MICROWIRE/PLUS Application

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space.

Address S/ADD REG	Contents
0000 to 006F	On-Chip RAM bytes (112 bytes)
0070 to 007F	Unused RAM Address Space (Reads As All Ones)
xx80 to xxAF	Unused RAM Address Space (Reads Undefined Data)
xxB0	Timer T3 Lower Byte
XXB1	Timer T3 Upper Byte
xxB2	Timer T3 Autoload Register T3RA Lower Byte
xxB3	Timer T3 Autoload Register T3RA Upper Byte
xxB4	Timer T3 Autoload Register T3RB Lower Byte
xxB5	Timer T3 Autoload Register T3RB Upper Byte
xxB6	Timer T3 Control Register
xxB7	Comparator Select Register (CMPSL)
xxB8	UART Transmit Buffer (TBUF)
xxB9	UART Receive Buffer (RBUF)
xxBA	UART Control and Status Register (ENU)
xxBB	UART Receive Control and Status Register (ENUR)
xxBC	UART Interrupt and Clock Source Register (ENUI)
xxBD	UART Baud Register (BAUD)
xxBE	UART Prescale Select Register (PSR)
xxBF	Reserved for UART
xxC0	Timer T2 Lower Byte
xxC1	Timer T2 Upper Byte
xxC2	Timer T2 Autoload Register T2RA Lower Byte
xxC3	Timer T2 Autoload Register T2RA Upper Byte
xxC4	Timer T2 Autoload Register T2RB Lower Byte
xxC5	Timer T2 Autoload Register T2RB Upper Byte
xxC6	Timer T2 Control Register
xxC7	WATCHDOG Service Register (Reg:WDSVR)
xxC8	MIWU Edge Select Register (Reg:WKEDG)
xxC9	MIWU Enable Register (Reg:WKEN)
xxCA	MIWU Pending Register (Reg:WKPND)
xxCB	Reserved
xxCC	Reserved
xxCD to xxCF	Reserved

Address S/ADD REG	Contents
xxD0	Port L Data Register
xxD1	Port L Configuration Register
xxD2	Port L Input Pins (Read Only)
xxD3	Reserved for Port L
xxD4	Port G Data Register
xxD5	Port G Configuration Register
xxD6	Port G Input Pins (Read Only)
xxD7	Port I Input Pins (Read Only)
xxD8	Port C Data Register
xxD9	Port C Configuration Register
xxDA	Port C Input Pins (Read Only)
xxDB	Reserved for Port C
xxDC	Port D
xxDD to DF	Reserved for Port D
xxE0 to xxE5	Reserved for EE Control Registers
xxE6	Timer T1 Autoload Register T1RB Lower Byte
xxE7	Timer T1 Autoload Register T1RB Upper Byte
xxE8	ICNTRL Register
xxE9	MICROWIRE/PLUS Shift Register
xxEA	Timer T1 Lower Byte
xxEB	Timer T1 Upper Byte
xxEC	Timer T1 Autoload Register T1RA Lower Byte
xxED	Timer T1 Autoload Register T1RA Upper Byte
xxEE	CNTRL Control Register
xxEF	PSW Register
xxF0 to FB	On-Chip RAM Mapped as Registers
xxFC	X Register
xxFD	SP Register
xxFE	B Register
xxFF	S Register
0100–013F	On-Chip 64 RAM Bytes

Reading memory locations 0070H–007FH (Segment 0) will return all ones. Reading unused memory locations 0080H–00AFH (Segment 0) will return undefined data. Reading unused memory locations 0140–017F (Segment 1) will return all ones. Reading memory locations from other Segments (i.e., Segment 2, Segment 3, ... etc.) will return all ones.

Addressing Modes

There are ten addressing modes, six for operand addressing and four for transfer of control.

OPERAND ADDRESSING MODES

Register Indirect

This is the "normal" addressing mode. The operand is the data memory addressed by the B pointer or X pointer.

Register Indirect (with auto post increment or decrement of pointer)

This addressing mode is used with the LD and X instructions. The operand is the data memory addressed by the B pointer or X pointer. This is a register indirect mode that automatically post increments or decrements the B or X register after executing the instruction.

Direct

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

Immediate

The instruction contains an 8-bit immediate field as the operand.

Short Immediate

This addressing mode is used with the Load B Immediate instruction. The instruction contains a 4-bit immediate field as the operand.

Indirect

This addressing mode is used with the LAID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a data operand from the program memory.

TRANSFER OF CONTROL ADDRESSING MODES

Relative

This mode is used for the JP instruction, with the instruction field being added to the program counter to get the new program location. JP has a range from -31 to +32 to allow a 1-byte relative jump (JP + 1 is implemented by a NOP instruction). There are no "pages" when using JP, since all 15 bits of PC are used.

Absolute

This mode is used with the JMP and JSR instructions, with the instruction field of 12 bits replacing the lower 12 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory segment.

Absolute Long

This mode is used with the JMPL and JSRL instructions, with the instruction field of 15 bits replacing the entire 15 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory space.

Indirect

This mode is used with the JID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a location in the program memory. The contents of this program memory location serve as a partial address (lower 8 bits of PC) for the jump to the next instruction.

Note: The VIS is a special case of the Indirect Transfer of Control addressing mode, where the double byte vector associated with the interrupt is transferred from adjacent addresses in the program memory into the program counter (PC) in order to jump to the associated interrupt service routine.

Instruction Set

Register and Symbol Definition

Registers	
A	8-Bit Accumulator Register
B	8-Bit Address Register
X	8-Bit Address Register
SP	8-Bit Stack Pointer Register
PC	15-Bit Program Counter Register
PU	Upper 7 Bits of PC
PL	Lower 8 Bits of PC
C	1 Bit of PSW Register for Carry
HC	1 Bit of PSW Register for Half Carry
GIE	1 Bit of PSW Register for Global Interrupt Enable
VU	Interrupt Vector Upper Byte
VL	Interrupt Vector Lower Byte

Symbols	
[B]	Memory Indirectly Addressed by B Register
[X]	Memory Indirectly Addressed by X Register
MD	Direct Addressed Memory
Mem	Direct Addressed Memory or [B]
Meml	Direct Addressed Memory or [B] or Immediate Data
Imm	8-Bit Immediate Data
Reg	Register Memory: Addresses F0 to FF (Includes B, X and SP)
Bit	Bit Number (0 to 7)
←	Loaded with
↔	Exchanged with

Instruction Set (Continued)

INSTRUCTION SET

ADD	A,Meml	ADD	$A \leftarrow A + \text{Meml}$
ADC	A,Meml	ADD with Carry	$A \leftarrow A + \text{Meml} + C$, $C \leftarrow \text{Carry}$
SUBC	A,Meml	Subtract with Carry	$HC \leftarrow \text{Half Carry}$ $A \leftarrow A - \text{Meml} + C$, $C \leftarrow \text{Carry}$ $HC \leftarrow \text{Half Carry}$
AND	A,Meml	Logical AND	$A \leftarrow A \text{ and Meml}$
ANDSZ	A,Imm	Logical AND Immed., Skip if Zero	Skip next if $(A \text{ and Imm}) = 0$
OR	A,Meml	Logical OR	$A \leftarrow A \text{ or Meml}$
XOR	A,Meml	Logical EXclusive OR	$A \leftarrow A \text{ xor Meml}$
IFEQ	MD,Imm	IF EQUAL	Compare MD and Imm, Do next if $MD = \text{Imm}$
IFEQ	A,Meml	IF EQUAL	Compare A and Meml, Do next if $A = \text{Meml}$
IFNE	A,Meml	IF Not Equal	Compare A and Meml, Do next if $A \neq \text{Meml}$
IFGT	A,Meml	IF Greater Than	Compare A and Meml, Do next if $A > \text{Meml}$
IFBNE	#	If B Not Equal	Do next if lower 4 bits of $B \neq \text{Imm}$
DRSZ	Reg	Decrement Reg., Skip if Zero	$\text{Reg} \leftarrow \text{Reg} - 1$, Skip if $\text{Reg} = 0$
SBIT	#,Mem	Set BIT	1 to bit, Mem (bit = 0 to 7 immediate)
RBIT	#,Mem	Reset BIT	0 to bit, Mem
IFBIT	#,Mem	IF BIT	If bit in A or Mem is true do next instruction
RPND		Reset PeNDing Flag	Reset Software Interrupt Pending Flag
X	A,Mem	EXchange A with Memory	$A \leftrightarrow \text{Mem}$
X	A,[X]	EXchange A with Memory [X]	$A \leftrightarrow [X]$
LD	A,Meml	LoAD A with Memory	$A \leftarrow \text{Meml}$

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instructions taking two bytes).

Most single byte instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

Bytes and Cycles per Instruction

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

	[B]	Direct	Immed.

Where,

i is the immediate data

Md is a directly addressed memory location

* is an unused opcode

Note: The opcode 60 Hex is also the opcode for IFBIT #i,A**Mask Options**

The COP888CG mask programmable options are shown below. The options are programmed at the same time as the ROM pattern submission.

OPTION 1: CLOCK CONFIGURATION

- = 1 Crystal Oscillator (CKI/10)
 - G7 (CKO) is clock generator output to crystal/resonator
 - CKI is the clock input
- = 2 Single-pin RC controlled oscillator (CKI/10)
 - G7 is available as a HALT restart and/or general purpose input

OPTION 2: HALT

- = 1 Enable HALT mode
- = 2 Disable HALT mode

OPTION 3: BONDING OPTIONS

- = 1 44-Pin PLCC
- = 2 40-Pin DIP
- = 3 N/A
- = 4 28-Pin DIP

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (if clock option-1 has been selected). The CKI input frequency is divided down by 10 to produce the instruction cycle clock (1/t_c).

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface or maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bar graph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use window interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC® via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS-232 serial interface cable
MHW-PS3	Power supply 110V/60 MHz
MHW-PS4	Power supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MHW-884CG28D5PC	28 DIP	4.5V-5.5V	COP884CG
MHW-884CG28DWPC	28 DIP	2.5V-6.0V	COP884CG
MHW-888CG40D5PC	40 DIP	4.5V-5.5V	COP888CG
MHW-888CG40DWPC	40 DIP	2.5V-6.0V	COP888CG
MWH-888CG44D5PC	44 PLCC	4.5V-5.5V	COP888CG
MHW-888CG44DWPC	44 PLCC	2.5V-6.0V	COP888CG

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM®, PC-/XT®, PC-AT® or compatible	424410527-001

Development Support (Continued)

SIMULATOR

The COP8 Designer's Tool Kit is available for evaluating National Semiconductor's COP8 microcontroller family. The kit contains programmer's manuals, device datasheets, pocket reference guide, assembler and simulator, which allows the user to write, test, debug and run code on an industry standard compatible PC. The simulator has a windowed user interface and can handle script files that simulate hardware inputs, interrupts and automatic command processing. The capture file feature enables the user to record to a file current cycle count and output port changes which are caused by the program under test.

Simulator Ordering Information

Part Number	Description	Manual
COP8-TOOL-KIT	COP8 Designer's Tool Kit Assembler and Simulator	420420270-001 424420269-001

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulator device specific datasheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 Baud

Set-up: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs., 7 Days

COP688EG/COP684EG/COP888EG/COP884EG

Single-Chip microCMOS Microcontrollers

General Description

The COP888 family of microcontrollers uses an 8-bit single chip core architecture fabricated with National Semiconductor's M²CMOS™ process technology. The COP888EG/COP884EG is a member of this expandable 8-bit core processor family of microcontrollers. (Continued)

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μs instruction cycle time
- 8k bytes on-board ROM
- 256 bytes on-board RAM
- Single supply operation: 2.5V–6V
- Full duplex UART
- Two analog comparators
- MICROWIRE/PLUS™ serial I/O
- WATCHDOG™ and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- Three 16-bit timers, each with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Fourteen multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Three Timers (Each with 2 Interrupts)
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - UART (2)
 - Default VIS
- Versatile instruction set
- True bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 PLCC or 40 N or 28 N or 28 SO
 - 44 PLCC with 39 I/O pins
 - 40 N with 35 I/O pins
 - 28 SO or 28 N, each with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Temperature ranges: –40°C to +85°C, –55°C to +125°C
- Form factor emulation devices
- Real time emulation and full program debug offered by National's Development Systems

Block Diagram

FIGURE 1. COP888EG Block Diagram

TL/DD/11214-1

General Description (Continued)

They are fully static parts, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS serial I/O, three 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), full duplex UART, two comparators, and two power savings modes

(HALT and IDLE), both with a multi-sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The devices operate over a voltage range of 2.5V to 6V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The device contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input (Schmitt trigger inputs on ports L and G), output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. (See the memory map for the various addresses associated with the I/O ports.) Figure 3 shows the I/O port configurations. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

PORT L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

The Port L supports Multi-Input Wake Up on all eight pins. L1 is used for the UART external clock. L2 and L3 are used for the UART transmit and receive. L4 and L5 are used for the timer input functions T2A and T2B. L6 and L7 are used for the timer input functions T3A and T3B.

The Port L has the following alternate features:

L0	MIWU
L1	MIWU or CKX
L2	MIWU or TDx
L3	MIWU or RDX
L4	MIWU or T2A
L5	MIWU or T2B
L6	MIWU or T3A
L7	MIWU or T3B

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOUT WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin but is also used to bring the device out of HALT mode with a low to high transition on G7. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

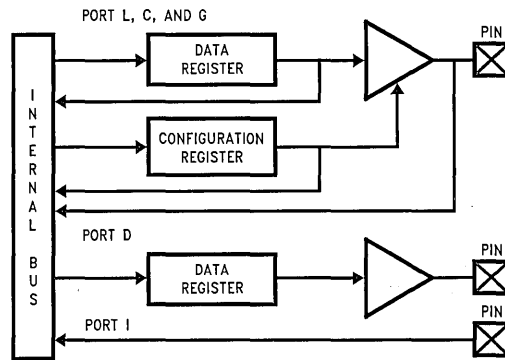

FIGURE 3. I/O Port Configurations

TL/DD/11214-6

Pin Descriptions (Continued)

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin (crystal clock option) or general purpose input (R/C clock option), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE™ Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

- G1 WDOUT WATCHDOG and/or Clock Monitor dedicated output
- G7 CKO Oscillator dedicated output or general purpose input

Port C is an 8-bit I/O port. The 40-pin device does not have a full complement of Port C pins. The unavailable pins are not terminated. A read operation for these unterminated pins will return unpredictable values.

PORT I is an eight-bit Hi-Z input port. The 28-pin device does not have a full complement of Port I pins. The unavailable pins are not terminated i.e., they are floating. A read operation for these unterminated pins will return unpredictable values. The user must ensure that the software takes this into account by either masking or restricting the accesses to bit operations. The unterminated Port I pins will draw power only when addressed.

Port I1–I3 are used for Comparator 1. Port I4–I6 are used for Comparator 2.

The Port I has the following alternate features.

- I1 COMP1–IN (Comparator 1 Negative Input)
- I2 COMP1+IN (Comparator 1 Positive Input)
- I3 COMP1OUT (Comparator 1 Output)
- I4 COMP2–IN (Comparator 2 Negative Input)
- I5 COMP2+IN (Comparator 2 Positive Input)
- I6 COMP2OUT (Comparator 2 Output)

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Functional Description

The architecture of the device is modified Harvard architecture. With the Harvard architecture, the control store program memory (ROM) is separated from the data store memory (RAM). Both ROM and RAM have their own separate addressing space with separate address buses. The architecture, though based on Harvard architecture, permits transfer of data from ROM to RAM.

CPU REGISTERS

The CPU can do an 8-bit addition, subtraction, logical or shift operation in one instruction (t_c) cycle time.

There are six CPU registers:

A is the 8-bit Accumulator Register

PC is the 15-bit Program Counter Register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is an 8-bit RAM address pointer, which can be optionally post auto incremented or decremented.

X is an 8-bit alternate RAM address pointer, which can be optionally post auto incremented or decremented.

SP is the 8-bit stack pointer, which points to the subroutine/interrupt stack (in RAM). The SP is initialized to RAM address 06F with reset.

S is the 8-bit Data Segment Address Register used to extend the lower half of the address range (00 to 7F) into 256 data segments of 128 bytes each.

All the CPU registers are memory mapped with the exception of the Accumulator (A) and the Program Counter (PC).

PROGRAM MEMORY

The program memory consists of 8092 bytes of ROM. These bytes may hold program instructions or constant data (data tables for the LAID instruction, jump vectors for the JID instruction, and interrupt vectors for the VIS instruction). The program memory is addressed by the 15-bit program counter (PC). All interrupts in the devices vector to program memory location 0FF Hex.

DATA MEMORY

The data memory address space includes the on-chip RAM and data registers, the I/O registers (Configuration, Data and Pin), the control registers, the MICROWIRE/PLUS SIO shift register, and the various registers, and counters associated with the timers (with the exception of the IDLE timer). Data memory is addressed directly by the instruction or indirectly by the B, X, SP pointers and S register.

The data memory consists of 256 bytes of RAM. Sixteen bytes of RAM are mapped as "registers" at addresses 0F0 to 0FF Hex. These registers can be loaded immediately, and also decremented and tested with the DRSZ (decrement register and skip if zero) instruction. The memory pointer registers X, SP, B and S are memory mapped into this space at address locations 0FC to 0FF Hex respectively, with the other registers being available for general usage. The instruction set permits any bit in memory to be set, reset or tested. All I/O and registers (except A and PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested. The accumulator (A) bits can also be directly and individually tested.

Data Memory Segment RAM Extension

Data memory address 0FF is used as a memory mapped location for the Data Segment Address Register (S).

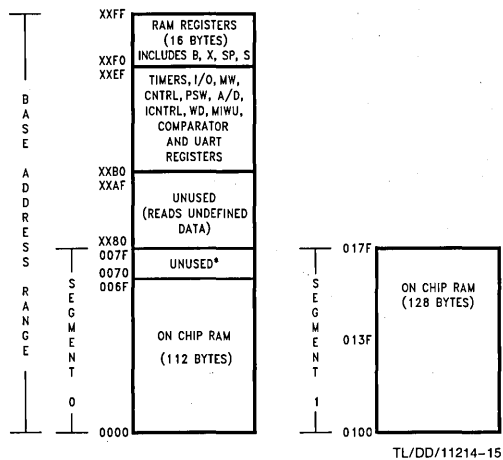

The data store memory is either addressed directly by a single byte address within the instruction, or indirectly relative to the reference of the B, X, or SP pointers (each contains a single-byte address). This single-byte address allows an addressing range of 256 locations from 00 to FF hex. The upper bit of this single-byte address divides the data store memory into two separate sections as outlined previously. With the exception of the RAM register memory from address locations 00F0 to 00FF, all RAM memory is memory mapped with the upper bit of the single-byte address being equal to zero. This allows the upper bit of the single-byte address to determine whether or not the base address range (from 0000 to 00FF) is extended. If this upper bit equals one (representing address range 0080 to 00FF), then address extension does not take place. Alternatively, if this upper bit equals zero, then the data segment extension register S is used to extend the base address range (from 0000 to 007F) from XX00 to XX7F, where XX represents the 8 bits from the S register. Thus the 128-byte data segment extensions are located from addresses 0100 to 017F for data segment 1, 0200 to 027F for data segment 2, etc., up to FF00 to FF7F for data segment 255. The base address range from 0000 to 007F represents data segment 0.

Figure 4 illustrates how the S register data memory extension is used in extending the lower half of the base address range (00 to 7F hex) into 256 data segments of 128 bytes each, with a total addressing range of 32 kbytes from XX00 to XX7F. This organization allows a total of 256 data segments of 128 bytes each with an additional upper base segment of 128 bytes. Furthermore, all addressing modes are available for all data segments. The S register must be changed under program control to move from one data segment (128 bytes) to another. However, the upper base segment (containing the 16 memory registers, I/O registers, control registers, etc.) is always available regardless of the contents of the S register, since the upper base segment (address range 0080 to 00FF) is independent of data segment extension.

The instructions that utilize the stack pointer (SP) always reference the stack as part of the base segment (Segment 0), regardless of the contents of the S register. The S register is not changed by these instructions. Consequently, the stack (used with subroutine linkage and interrupts) is always located in the base segment. The stack pointer will be initialized to point at data memory location 006F as a result of reset.

The 128 bytes of RAM contained in the base segment are split between the lower and upper base segments. The first 116 bytes of RAM are resident from address 0000 to 006F in the lower base segment, while the remaining 16 bytes of RAM represent the 16 data memory registers located at addresses 00F0 to 00FF of the upper base segment. No RAM is located at the upper sixteen addresses (0070 to 007F) of the lower base segment.

Additional RAM beyond these initial 128 bytes, however, will always be memory mapped in groups of 128 bytes (or less) at the data segment address extensions (XX00 to XX7F) of the lower base segment. The additional 128 bytes of RAM are memory mapped at address locations 0100 to 017F hex.

*Reads as all ones.

FIGURE 4. RAM Organization

Reset

The $\overline{\text{RESET}}$ input when pulled low initializes the microcontroller. Initialization will occur whenever the $\overline{\text{RESET}}$ input is pulled low. Upon initialization, the data and configuration registers for ports L, G and C are cleared, resulting in these Ports being initialized to the TRI-STATE mode. Pin G1 of the G Port is an exception (as noted below) since pin G1 is dedicated as the WATCHDOG and/or Clock Monitor error output pin. Port D is set high. The PC, PSW, ICNTRL, CNTRL, T2CNTRL and T3CNTRL control registers are cleared. The UART registers PSR, ENU (except that TBMT bit is set), ENUR and ENUI are cleared. The Comparator Select Register is cleared. The S register is initialized to zero. The Multi-Input Wakeup registers WKEN, WKEDG and WKPND are cleared. The stack pointer, SP, is initialized to 6F Hex.

The device comes out of reset with both the WATCHDOG logic and the Clock Monitor detector armed, with the WATCHDOG service window bits set and the Clock Monitor bit set. The WATCHDOG and Clock Monitor circuits are inhibited during reset. The WATCHDOG service window bits being initialized high default to the maximum WATCHDOG service window of $64k t_C$ clock cycles. The Clock Monitor bit being initialized high will cause a Clock Monitor error following reset if the clock has not reached the minimum specified frequency at the termination of reset. A Clock Monitor error will cause an active low error output on pin G1. This error output will continue until $16 t_C - 32 t_C$ clock cycles following the clock frequency reaching the minimum specified value, at which time the G1 output will enter the TRI-STATE mode.

The external RC network shown in Figure 5 should be used to ensure that the $\overline{\text{RESET}}$ pin is held low until the power supply to the chip stabilizes.

Reset (Continued)

$RC > 5 \times$ Power Supply Rise Time

FIGURE 5. Recommended Reset Circuit

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Figure 6 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table A shows the component values required for various standard crystal values.

R/C OSCILLATOR

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart input.

Table B shows the variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/11214-18

6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5V$

Note: $3k \leq R \leq 200k$

$50 \text{ pF} \leq C \leq 200 \text{ pF}$

Current Drain

The total current drain of the chip depends on:

1. Oscillator operation mode—I1
2. Internal switching current—I2
3. Internal leakage current—I3
4. Output source current—I4
5. DC current caused by external input not at V_{CC} or GND—I5
6. Comparator DC supply current when enabled—I6
7. Clock Monitor current when enabled—I7

Thus the total current drain, I_t is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5 + I_6 + I_7$$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw more current as the CKI input frequency increases up to the maximum 10 MHz value. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

where C = equivalent capacitance of the chip

V = operating voltage

f = CKI frequency

Control Registers

CNTRL Register (Address X'00EE)

The Timer1 (T1) and MICROWIRE/PLUS control register contains the following bits:

- SL1 & SL0 Select the MICROWIRE/PLUS clock divide by (00 = 2, 01 = 4, 1x = 8)
- IEDG External interrupt edge polarity select (0 = Rising edge, 1 = Falling edge)
- MSEL Selects G5 and G4 as MICROWIRE/PLUS signals SK and SO respectively
- T1C0 Timer T1 Start/Stop control in timer modes 1 and 2
Timer T1 Underflow Interrupt Pending Flag in timer mode 3
- T1C1 Timer T1 mode control bit
- T1C2 Timer T1 mode control bit
- T1C3 Timer T1 mode control bit

T1C3	T1C2	T1C1	T1C0	MSEL	IEDG	SL1	SL0
------	------	------	------	------	------	-----	-----

Bit 7

Bit 0

Control Registers (Continued)

PSW Register (Address X'00EF)

The PSW register contains the following select bits:

GIE	Global interrupt enable (enables interrupts)
EXEN	Enable external interrupt
BUSY	MICROWIRE/PLUS busy shifting flag
EXPND	External interrupt pending
T1ENA	Timer T1 Interrupt Enable for Timer Underflow or T1A Input capture edge
T1PND	Timer T1 Interrupt Pending Flag (Autoreload RA in mode 1, T1 Underflow in Mode 2, T1A capture edge in mode 3)
C	Carry Flag
HC	Half Carry Flag

HC	C	T1PND	T1ENA	EXPND	BUSY	EXEN	GIE
----	---	-------	-------	-------	------	------	-----

Bit 7

Bit 0

The Half-Carry bit is also affected by all the instructions that affect the Carry flag. The SC (Set Carry) and RC (Reset Carry) instructions will respectively set or clear both the carry flags. In addition to the SC and RC instructions, ADC, SUBC, RRC and RLC instructions affect the carry and Half Carry flags.

ICNTRL Register (Address X'00E8)

The ICNTRL register contains the following bits:

T1ENB	Timer T1 Interrupt Enable for T1B Input capture edge
T1PNDB	Timer T1 Interrupt Pending Flag for T1B capture edge
μ WEN	Enable MICROWIRE/PLUS interrupt
μ WPND	MICROWIRE/PLUS interrupt pending
T0EN	Timer T0 Interrupt Enable (Bit 12 toggle)
T0PND	Timer T0 Interrupt pending
LPEN	L Port Interrupt Enable (Multi-Input Wakeup/Interrupt)
Bit 7 could be used as a flag

Bit 7

Bit 0

Timers

The device contains a very versatile set of timers (T0, T1, T2, T3). All timers and associated autoreload/capture registers power up containing random data.

TIMER T0 (IDLE TIMER)

The devices support applications that require maintaining real time and low power with the IDLE mode. This IDLE mode support is furnished by the IDLE timer T0, which is a 16-bit timer. The Timer T0 runs continuously at the fixed rate of the instruction cycle clock, t_c . The user cannot read or write to the IDLE Timer T0, which is a count down timer.

The Timer T0 supports the following functions:

Exit out of the Idle Mode (See Idle Mode description)

WATCHDOG logic (See WATCHDOG description)

Start up delay out of the HALT mode

The IDLE Timer T0 can generate an interrupt when the thirteenth bit toggles. This toggle is latched into the T0PND pending flag, and will occur every 4 ms at the maximum clock frequency ($t_c = 1 \mu s$). A control flag T0EN allows the interrupt from the thirteenth bit of Timer T0 to be enabled or disabled. Setting T0EN will enable the interrupt, while resetting it will disable the interrupt.

Timers (Continued)

TIMER T1, TIMER T2 AND TIMER T3

The devices have a set of three powerful timer/counter blocks, T1, T2 and T3. The associated features and functioning of a timer block are described by referring to the timer block Tx. Since the three timer blocks, T1, T2 and T3 are identical, all comments are equally applicable to any of the three timer blocks.

Each timer block consists of a 16-bit timer, Tx, and two supporting 16-bit autoreload/capture registers, RxA and RxB. Each timer block has two pins associated with it, TxA and TxB. The pin TxA supports I/O required by the timer block, while the pin TxB is an input to the timer block. The powerful and flexible timer block allows the device to easily perform all timer functions with minimal software overhead. The timer block has three operating modes: Processor Independent PWM mode, External Event Counter mode, and Input Capture mode.

The control bits TxC3, TxC2, and TxC1 allow selection of the different modes of operation.

Mode 1. Processor Independent PWM Mode

As the name suggests, this mode allows the device to generate a PWM signal with very minimal user intervention. The user only has to define the parameters of the PWM signal (ON time and OFF time). Once begun, the timer block will continuously generate the PWM signal completely independent of the microcontroller. The user software services the timer block only when the PWM parameters require updating.

In this mode the timer Tx counts down at a fixed rate of t_c . Upon every underflow the timer is alternately reloaded with the contents of supporting registers, RxA and RxB. The very first underflow of the timer causes the timer to reload from the register RxA. Subsequent underflows cause the timer to be reloaded from the registers alternately beginning with the register RxB.

The Tx Timer control bits, TxC3, TxC2 and TxC1 set up the timer for PWM mode operation.

Figure 7 shows a block diagram of the timer in PWM mode. The underflows can be programmed to toggle the TxA output pin. The underflows can also be programmed to generate interrupts.

Underflows from the timer are alternately latched into two pending flags, TxPND A and TxPND B. The user must reset these pending flags under software control. Two control enable flags, TxENA and TxENB, allow the interrupts from the timer underflow to be enabled or disabled. Setting the timer enable flag TxENA will cause an interrupt when a timer underflow causes the RxA register to be reloaded into the timer. Setting the timer enable flag TxENB will cause an interrupt when a timer underflow causes the RxB register to be reloaded into the timer. Resetting the timer enable flags will disable the associated interrupts.

Either or both of the timer underflow interrupts may be enabled. This gives the user the flexibility of interrupting once per PWM period on either the rising or falling edge of the PWM output. Alternatively, the user may choose to interrupt on both edges of the PWM output.

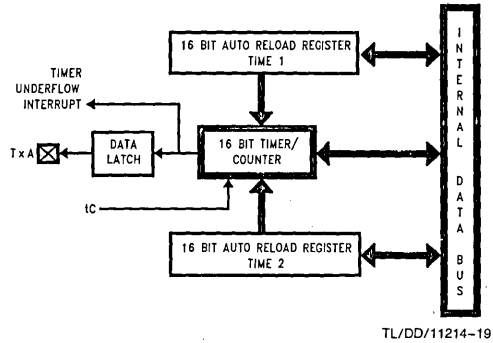

FIGURE 7. Timer in PWM Mode

Mode 2. External Event Counter Mode

This mode is quite similar to the processor independent PWM mode described above. The main difference is that the timer, Tx, is clocked by the input signal from the TxA pin. The Tx timer control bits, TxC3, TxC2 and TxC1 allow the timer to be clocked either on a positive or negative edge from the TxA pin. Underflows from the timer are latched into the TxPND A pending flag. Setting the TxENA control flag will cause an interrupt when the timer underflows.

In this mode the input pin TxB can be used as an independent positive edge sensitive interrupt input if the TxENB control flag is set. The occurrence of a positive edge on the TxB input pin is latched into the TxPND B flag.

Figure 8 shows a block diagram of the timer in External Event Counter mode.

Note: The PWM output is not available in this mode since the TxA pin is being used as the counter input clock.

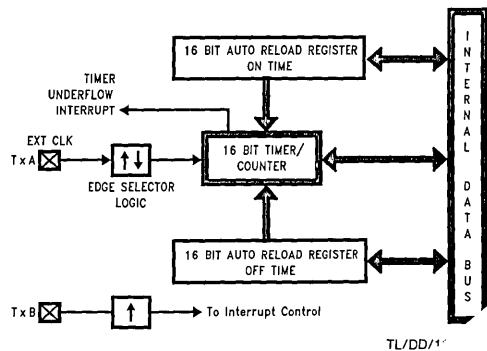

FIGURE 8. Timer in External Event Counter Mode

Mode 3. Input Capture Mode

The device can precisely measure external time external events by placing the timer in input capture mode.

In this mode, the timer Tx is clocked at the t_c rate. The two registers, RxA and RxB, are used to capture the time of an event. Each register, RxA and RxB, acts as an input capture register. RxA acts as the rising edge capture register and RxB acts as the falling edge capture register.

Timers (Continued)

The timer value gets copied over into the register when a trigger event occurs on its corresponding pin. Control bits, TxC3, TxC2 and TxC1, allow the trigger events to be specified either as a positive or a negative edge. The trigger condition for each input pin can be specified independently.

The trigger conditions can also be programmed to generate interrupts. The occurrence of the specified trigger condition on the TxA and TxB pins will be respectively latched into the pending flags, TxPND A and TxPND B. The control flag TxENA allows the interrupt on TxA to be either enabled or disabled. Setting the TxENA flag enables interrupts to be generated when the selected trigger condition occurs on the TxA pin. Similarly, the flag TxENB controls the interrupts from the TxB pin.

Underflows from the timer can also be programmed to generate interrupts. Underflows are latched into the timer TxCO pending flag (the TxCO control bit serves as the timer underflow interrupt pending flag in the Input Capture mode). Consequently, the TxCO control bit should be reset when entering the Input Capture mode. The timer underflow interrupt is enabled with the TxENA control flag. When a TxA interrupt occurs in the Input Capture mode, the user must check both the TxPND A and TxCO pending flags in order to determine whether a TxA input capture or a timer underflow (or both) caused the interrupt.

Figure 9 shows a block diagram of the timer in Input Capture mode.

TL/DD/11214-21

FIGURE 9. Timer in Input Capture Mode

TIMER CONTROL FLAGS

The timers T1, T2 and T3 have identical control structures. The control bits and their functions are summarized below.

TxC0	Timer Start/Stop control in Modes 1 and 2 (Processor Independent PWM and External Event Counter), where 1 = Start, 0 = Stop Timer Underflow Interrupt Pending Flag in Mode 3 (Input Capture)
TxPND A	Timer Interrupt Pending Flag
TxPND B	Timer Interrupt Pending Flag
TxENA	Timer Interrupt Enable Flag
TxENB	Timer Interrupt Enable Flag 1 = Timer Interrupt Enabled 0 = Timer Interrupt Disabled
TxC3	Timer mode control
TxC2	Timer mode control
TxC1	Timer mode control

Timers (Continued)

The timer mode control bits (TxC3, TxC2 and TxC1) are detailed below:

TxC3	TxC2	TxC1	Timer Mode	Interrupt A Source	Interrupt B Source	Timer Counts On
0	0	0	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Pos. Edge
0	0	1	MODE 2 (External Event Counter)	Timer Underflow	Pos. TxB Edge	TxA Neg. Edge
1	0	1	MODE 1 (PWM) TxA Toggle	Autoreload RA	Autoreload RB	t_c
1	0	0	MODE 1 (PWM) No TxA Toggle	Autoreload RA	Autoreload RB	t_c
0	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Pos. Edge	Pos. TxA Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	0	MODE 3 (Capture) Captures: TxA Pos. Edge TxB Neg. Edge	Pos. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c
0	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Pos. Edge	Neg. TxB Edge or Timer Underflow	Pos. TxB Edge	t_c
1	1	1	MODE 3 (Capture) Captures: TxA Neg. Edge TxB Neg. Edge	Neg. TxA Edge or Timer Underflow	Neg. TxB Edge	t_c

Power Save Modes

The devices offer the user two power save modes of operation: HALT and IDLE. In the HALT mode, all microcontroller activities are stopped. In the IDLE mode, the on-board oscillator circuitry the WATCHDOG logic, the Clock Monitor and timer T0 are active but all other microcontroller activities are stopped. In either mode, all on-board RAM, registers, I/O states, and timers (with the exception of T0) are unaltered.

HALT MODE

The devices can be placed in the HALT mode by writing a "1" to the HALT flag (G7 data bit). All microcontroller activities, including the clock and timers, are stopped. The WATCHDOG logic on the device is disabled during the HALT mode. However, the clock monitor circuitry if enabled remains active and will cause the WATCHDOG output pin (WDOUT) to go low. If the HALT mode is used and the user does not want to activate the WDOUT pin, the Clock Monitor should be disabled after the device comes out of reset (resetting the Clock Monitor control bit with the first write to the WDSVR register). In the HALT mode, the power requirements of the device are minimal and the applied voltage (V_{CC}) may be decreased to V_r ($V_r = 2.0V$) without altering the state of the machine.

The devices support three different ways of exiting the HALT mode. The first method of exiting the HALT mode is with the Multi-Input Wakeup feature on the L port. The second method is with a low to high transition on the CKO (G7) pin. This method precludes the use of the crystal clock con-

figuration (since CKO becomes a dedicated output), and so may be used with an RC clock configuration. The third method of exiting the HALT mode is by pulling the RESET pin low.

Since a crystal or ceramic resonator may be selected as the oscillator, the Wakeup signal is not allowed to start the chip running immediately since crystal oscillators and ceramic resonators have a delayed start up time to reach full amplitude and frequency stability. The IDLE timer is used to generate a fixed delay to ensure that the oscillator has indeed stabilized before allowing instruction execution. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry is enabled. The IDLE timer is loaded with a value of 256 and is clocked with the t_c instruction cycle clock. The t_c clock is derived by dividing the oscillator clock down by a factor of 10. The Schmitt trigger following the CKI inverter on the chip ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If an RC clock option is being used, the fixed delay is introduced optionally. A control bit, CLKDLY, mapped as configuration bit G7, controls whether the delay is to be introduced or not. The delay is included if CLKDLY is set, and excluded if CLKDLY is reset. The CLKDLY bit is cleared on reset.

Power Save Modes (Continued)

The devices have two mask options associated with the HALT mode. The first mask option enables the HALT mode feature, while the second mask option disables the HALT mode. With the HALT mode enable mask option, the device will enter and exit the HALT mode as described above. With the HALT disable mask option, the device cannot be placed in the HALT mode (writing a "1" to the HALT flag will have no effect).

The WATCHDOG detector circuit is inhibited during the HALT mode. However, the clock monitor circuit if enabled remains active during HALT mode in order to ensure a clock monitor error if the device inadvertently enters the HALT mode as a result of a runaway program or power glitch.

IDLE MODE

The device is placed in the IDLE mode by writing a "1" to the IDLE flag (G6 data bit). In this mode, all activities, except the associated on-board oscillator circuitry, the WATCHDOG logic, the clock monitor and the IDLE Timer T0, are stopped. The power supply requirements of the microcontroller in this mode of operation are typically around 30% of normal power requirement of the microcontroller.

As with the HALT mode, the device can be returned to normal operation with a reset, or with a Multi-Input Wakeup from the L Port. Alternately, the microcontroller resumes normal operation from the IDLE mode when the thirteenth bit (representing 4.096 ms at internal clock frequency of 1 MHz, $t_c = 1 \mu s$) of the IDLE Timer toggles.

This toggle condition of the thirteenth bit of the IDLE Timer T0 is latched into the TOPND pending flag.

The user has the option of being interrupted with a transition on the thirteenth bit of the IDLE Timer T0. The interrupt can be enabled or disabled via the T0EN control bit. Setting the T0EN flag enables the interrupt and vice versa.

The user can enter the IDLE mode with the Timer T0 interrupt enabled. In this case, when the TOPND bit gets set, the device will first execute the Timer T0 interrupt service routine and then return to the instruction following the "Enter Idle Mode" instruction.

Alternatively, the user can enter the IDLE mode with the IDLE Timer T0 interrupt disabled. In this case, the device will resume normal operation with the instruction immediately following the "Enter Idle Mode" instruction.

Note: It is necessary to program two NOP instructions following both the set HALT mode and set IDLE mode instructions. These NOP instructions are necessary to allow clock resynchronization following the HALT or IDLE modes.

Multi-Input Wakeup

The Multi-Input Wakeup feature is used to return (wakeup) the device from either the HALT or IDLE modes. Alternately Multi-Input Wakeup/Interrupt feature may also be used to generate up to 8 edge selectable external interrupts.

Figure 10 shows the Multi-Input Wakeup logic.

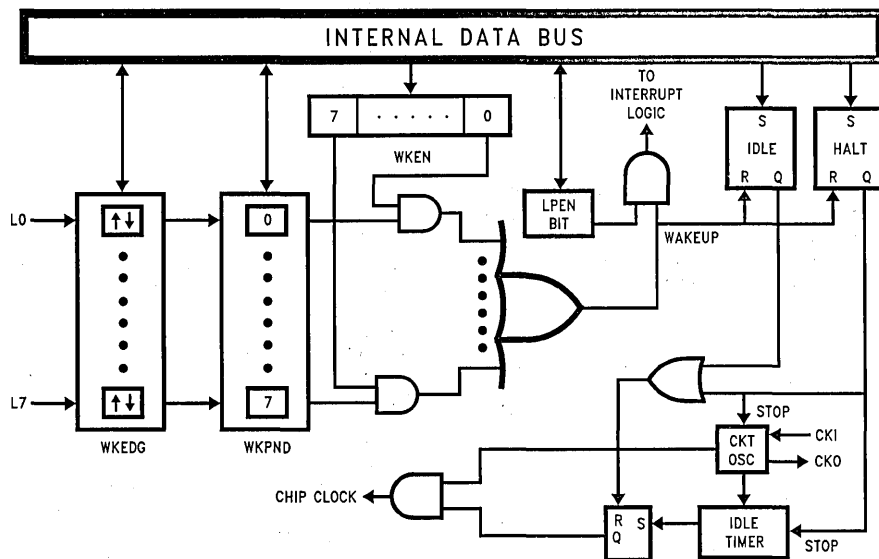

FIGURE 10. Multi-Input Wake Up Logic

TL/DD/11214-22

Multi-Input Wakeup (Continued)

The Multi-Input Wakeup feature utilizes the L Port. The user selects which particular L port bit (or combination of L Port bits) will cause the device to exit the HALT or IDLE modes. The selection is done through the Reg: WKEN. The Reg: WKEN is an 8-bit read/write register, which contains a control bit for every L port bit. Setting a particular WKEN bit enables a Wakeup from the associated L port pin.

The user can select whether the trigger condition on the selected L Port pin is going to be either a positive edge (low to high transition) or a negative edge (high to low transition). This selection is made via the Reg: WKEDG, which is an 8-bit control register with a bit assigned to each L Port pin. Setting the control bit will select the trigger condition to be a negative edge on that particular L Port pin. Resetting the bit selects the trigger condition to be a positive edge. Changing an edge select entails several steps in order to avoid a pseudo Wakeup condition as a result of the edge change. First, the associated WKEN bit should be reset, followed by the edge select change in WKEDG. Next, the associated WKPND bit should be cleared, followed by the associated WKEN bit being re-enabled.

An example may serve to clarify this procedure. Suppose we wish to change the edge select from positive (low going high) to negative (high going low) for L Port bit 5, where bit 5 has previously been enabled for an input interrupt. The program would be as follows:

```

RBIT 5, WKEN
SBIT 5, WKEDG
RBIT 5, WKPND
SBIT 5, WKEN

```

If the L port bits have been used as outputs and then changed to inputs with Multi-Input Wakeup/Interrupt, a safety procedure should also be followed to avoid inherited pseudo wakeup conditions. After the selected L port bits have been changed from output to input but before the associated WKEN bits are enabled, the associated edge select bits in WKEDG should be set or reset for the desired edge selects, followed by the associated WKPND bits being cleared.

This same procedure should be used following reset, since the L port inputs are left floating as a result of reset.

The occurrence of the selected trigger condition for Multi-Input Wakeup is latched into a pending register called WKPND. The respective bits of the WKPND register will be set on the occurrence of the selected trigger edge on the corresponding Port L pin. The user has the responsibility of clearing these pending flags. Since WKPND is a pending register for the occurrence of selected wakeup conditions, the device will not enter the HALT mode if any Wakeup bit is both enabled and pending. Consequently, the user has the responsibility of clearing the pending flags before attempting to enter the HALT mode.

WKEN, WKPND and WKEDG are all read/write registers, and are cleared at reset.

PORT L INTERRUPTS

Port L provides the user with an additional eight fully selectable, edge sensitive interrupts which are all vectored into the same service subroutine.

The interrupt from Port L shares logic with the wake up circuitry. The register WKEN allows interrupts from Port L to be individually enabled or disabled. The register WKEDG specifies the trigger condition to be either a positive or a negative edge. Finally, the register WKPND latches in the pending trigger conditions.

The GIE (Global Interrupt Enable) bit enables the interrupt function.

A control flag, LPEN, functions as a global interrupt enable for Port L interrupts. Setting the LPEN flag will enable interrupts and vice versa. A separate global pending flag is not needed since the register WKPND is adequate.

Since Port L is also used for waking the device out of the HALT or IDLE modes, the user can elect to exit the HALT or IDLE modes either with or without the interrupt enabled. If he elects to disable the interrupt, then the device will restart execution from the instruction immediately following the instruction that placed the microcontroller in the HALT or IDLE modes. In the other case, the device will first execute the interrupt service routine and then revert to normal operation.

The Wakeup signal will not start the chip running immediately since crystal oscillators or ceramic resonators have a finite start up time. The IDLE Timer (T₀) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the device to execute instructions. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry and the IDLE Timer T₀ are enabled. The IDLE Timer is loaded with a value of 256 and is clocked from the t_c instruction cycle clock. The t_c clock is derived by dividing down the oscillator clock by a factor of 10. A Schmitt trigger following the CKI on-chip inverter ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If the RC clock option is used, the fixed delay is under software control. A control flag, CLKDLY, in the G7 configuration bit allows the clock start up delay to be optionally inserted. Setting CLKDLY flag high will cause clock start up delay to be inserted and resetting it will exclude the clock start up delay. The CLKDLY flag is cleared during reset, so the clock start up delay is not present following reset with the RC clock options.

UART

The device contains a full-duplex software programmable UART. The UART (*Figure 11*) consists of a transmit shift register, a receiver shift register and seven addressable registers, as follows: a transmit buffer register (TBUF), a receiver buffer register (RBUF), a UART control and status register (ENU), a UART receive control and status register (ENUR), a UART interrupt and clock source register (ENUI), a prescaler select register (PSR) and baud (BAUD) register. The ENU register contains flags for transmit and receive functions; this register also determines the length of the data frame (7, 8 or 9 bits), the value of the ninth bit in transmission, and parity selection bits. The ENUR register flags framing, data overrun and parity errors while the UART is receiving.

Other functions of the ENUR register include saving the ninth bit received in the data frame, enabling or disabling the UART's attention mode of operation and providing additional receiver/transmitter status information via RCVG and XMTG bits. The determination of an internal or external clock source is done by the ENUI register, as well as selecting the number of stop bits and enabling or disabling transmit and receive interrupts. A control flag in this register can also select the UART mode of operation: asynchronous or synchronous.

ORW	ORW	ORW	ORW	ORW	ORW	ORW	ORW

Bit7 Bit0

*Bit is not used.

- 0 Bit is cleared on reset.
- 1 Bit is set to one on reset.
- R Bit is read-only; it cannot be written by software.
- RW Bit is read/write.
- D Bit is cleared on read; when read by software as a one, it is cleared automatically. Writing to the bit does not affect its state.

DESCRIPTION OF UART REGISTER BITS

ENU—UART CONTROL AND STATUS REGISTER

TBMT: This bit is set when the UART transfers a byte of data from the TBUF register into the TSFT register for transmission. It is automatically reset when software writes into the TBUF register.

RBFL: This bit is set when the UART has received a complete character and has copied it into the RBUF register. It is automatically reset when software reads the character from RBUF.

ERR: This bit is a global UART error flag which gets set if any or a combination of the errors (DOE, FE, PE) occur.

CHL1, CHL0: These bits select the character frame format. Parity is not included and is generated/verified by hardware.
 CHL1 = 0, CHL0 = 0 The frame contains eight data bits.
 CHL1 = 0, CHL0 = 1 The frame contains seven data bits.

CHL1 = 1, CHL0 = 0 The frame contains nine data bits.
 CHL1 = 1, CHL0 = 1 Loopback Mode selected. Transmitter output internally looped back to receiver input. Nine bit framing format is used.

XBIT9/PSEL0: Programs the ninth bit for transmission when the UART is operating with nine data bits per frame. For seven or eight data bits per frame, this bit in conjunction with PSEL1 selects parity.

PSEL1, PSEL0: Parity select bits.

- PSEL1 = 0, PSEL0 = 0 Odd Parity (if Parity enabled)
- PSEL1 = 0, PSEL0 = 1 Even Parity (if Parity enabled)

- PSEL1 = 1, PSEL0 = 0 Mark(1) (if Parity enabled)
- PSEL1 = 1, PSEL0 = 1 Space(0) (if Parity enabled)

PEN: This bit enables/disables Parity (7- and 8-bit modes only).

- PEN = 0 Parity disabled.
- PEN = 1 Parity enabled.

ENUR—UART RECEIVE CONTROL AND STATUS REGISTER

RCVG: This bit is set high whenever a framing error occurs and goes low when RDX goes high.

XMTG: This bit is set to indicate that the UART is transmitting. It gets reset at the end of the last frame (end of last Stop bit).

ATTN: ATTENTION Mode is enabled while this bit is set. This bit is cleared automatically on receiving a character with data bit nine set.

RBIT9: Contains the ninth data bit received when the UART is operating with nine data bits per frame.

SPARE: Reserved for future use.

PE: Flags a Parity Error.

- PE = 0 Indicates no Parity Error has been detected since the last time the ENUR register was read.
- PE = 1 Indicates the occurrence of a Parity Error.

FE: Flags a Framing Error.

- FE = 0 Indicates no Framing Error has been detected since the last time the ENUR register was read.
- FE = 1 Indicates the occurrence of a Framing Error.

DOE: Flags a Data Overrun Error.

- DOE = 0 Indicates no Data Overrun Error has been detected since the last time the ENUR register was read.
- DOE = 1 Indicates the occurrence of a Data Overrun Error.

ENUI—UART INTERRUPT AND CLOCK SOURCE REGISTER

ETI: This bit enables/disables interrupt from the transmitter section.

- ETI = 0 Interrupt from the transmitter is disabled.
- ETI = 1 Interrupt from the transmitter is enabled.

ERI: This bit enables/disables interrupt from the receiver section.

- ERI = 0 Interrupt from the receiver is disabled.
- ERI = 1 Interrupt from the receiver is enabled.

XTCLK: This bit selects the clock source for the transmitter section.

- XTCLK = 0 The clock source is selected through the PSR and BAUD registers.
- XTCLK = 1 Signal on CKX (L1) pin is used as the clock.

XRCLK: This bit selects the clock source for the receiver section.

- XRCLK = 0 The clock source is selected through the PSR and BAUD registers.
- XRCLK = 1 Signal on CKX (L1) pin is used as the clock.

SSEL: UART mode select.

- SSEL = 0 Asynchronous Mode.
- SSEL = 1 Synchronous Mode.

UART (Continued)

ETDX: TDX (UART Transmit Pin) is the alternate function assigned to Port L pin L2; it is selected by setting ETDX bit. To simulate line break generation, software should reset ETDX bit and output logic zero to TDX pin through Port L data and configuration registers.

STP78: This bit is set to program the last Stop bit to be 7/8th of a bit in length.

STP2: This bit programs the number of Stop bits to be transmitted.

STP2 = 0 One Stop bit transmitted.

STP2 = 1 Two Stop bits transmitted.

Associated I/O Pins

Data is transmitted on the TDX pin and received on the RDX pin. TDX is the alternate function assigned to Port L pin L2; it is selected by setting ETDX (in the ENUI register) to one. RDX is an inherent function of Port L pin L3, requiring no setup.

The baud rate clock for the UART can be generated on-chip, or can be taken from an external source. Port L pin L1 (CKX) is the external clock I/O pin. The CKX pin can be either an input or an output, as determined by Port L Configuration and Data registers (Bit 1). As an input, it accepts a clock signal which may be selected to drive the transmitter and/or receiver. As an output, it presents the internal Baud Rate Generator output.

UART Operation

The UART has two modes of operation: asynchronous mode and synchronous mode.

ASYNCHRONOUS MODE

This mode is selected by resetting the SSEL (in the ENUI register) bit to zero. The input frequency to the UART is 16 times the baud rate.

The TSFT and TBUF registers double-buffer data for transmission. While TSFT is shifting out the current character on the TDX pin, the TBUF register may be loaded by software with the next byte to be transmitted. When TSFT finishes transmitting the current character the contents of TBUF are transferred to the TSFT register and the Transmit Buffer Empty Flag (TBMT in the ENU register) is set. The TBMT flag is automatically reset by the UART when software loads a new character into the TBUF register. There is also the XMTG bit which is set to indicate that the UART is transmitting. This bit gets reset at the end of the last frame (end of last Stop bit). TBUF is a read/write register.

The RSFT and RBUF registers double-buffer data being received. The UART receiver continually monitors the signal on the RDX pin for a low level to detect the beginning of a Start bit. Upon sensing this low level, it waits for half a bit time and samples again. If the RDX pin is still low, the receiver considers this to be a valid Start bit, and the remaining bits in the character frame are each sampled a single time, at the mid-bit position. Serial data input on the RDX pin is shifted into the RSFT register. Upon receiving the complete character, the contents of the RSFT register are copied into the RBUF register and the Received Buffer Full Flag (RBFL) is set. RBFL is automatically reset when software reads the character from the RBUF register. RBUF is a read only register. There is also the RCVG bit which is set high

when a framing error occurs and goes low once RDX goes high. TBMT, XMTG, RBFL and RCVG are read only bits.

SYNCHRONOUS MODE

In this mode data is transferred synchronously with the clock. Data is transmitted on the rising edge and received on the falling edge of the synchronous clock.

This mode is selected by setting SSEL bit in the ENUI register. The input frequency to the UART is the same as the baud rate.

When an external clock input is selected at the CKX pin, data transmit and receive are performed synchronously with this clock through TDX/RDX pins.

If data transmit and receive are selected with the CKX pin as clock output, the device generates the synchronous clock output at the CKX pin. The internal baud rate generator is used to produce the synchronous clock. Data transmit and receive are performed synchronously with this clock.

FRAMING FORMATS

The UART supports several serial framing formats (*Figure 12*). The format is selected using control bits in the ENU, ENUR and ENUI registers.

The first format (1, 1a, 1b, 1c) for data transmission (CHL0 = 1, CHL1 = 0) consists of Start bit, seven Data bits (excluding parity) and 7/8, one or two Stop bits. In applications using parity, the parity bit is generated and verified by hardware.

The second format (CHL0 = 0, CHL1 = 0) consists of one Start bit, eight Data bits (excluding parity) and 7/8, one or two Stop bits. Parity bit is generated and verified by hardware.

The third format for transmission (CHL0 = 0, CHL1 = 1) consists of one Start bit, nine Data bits and 7/8, one or two Stop bits. This format also supports the UART "ATTENTION" feature. When operating in this format, all eight bits of TBUF and RBUF are used for data. The ninth data bit is transmitted and received using two bits in the ENU and ENUR registers, called XBIT9 and RBIT9. RBIT9 is a read only bit. Parity is not generated or verified in this mode.

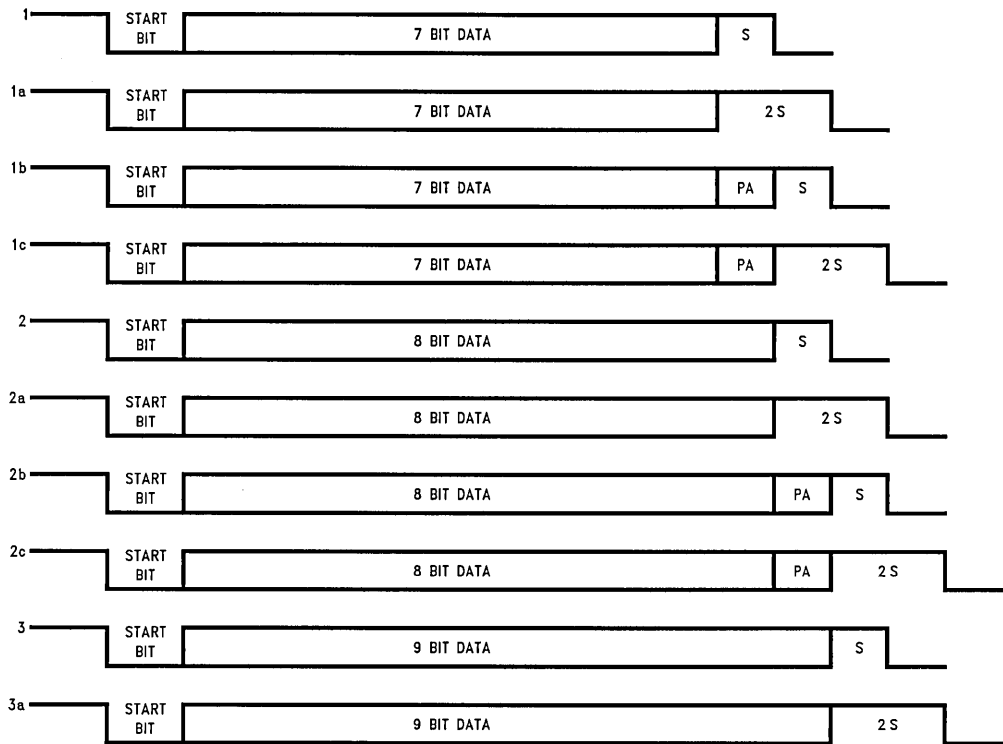

For any of the above framing formats, the last Stop bit can be programmed to be 7/8th of a bit in length. If two Stop bits are selected and the 7/8th bit is set (selected), the second Stop bit will be 7/8th of a bit in length.

The parity is enabled/disabled by PEN bit located in the ENU register. Parity is selected for 7- and 8-bit modes only. If parity is enabled (PEN = 1), the parity selection is then performed by PSEL0 and PSEL1 bits located in the ENU register.

Note that the XBIT9/PSEL0 bit located in the ENU register serves two mutually exclusive functions. This bit programs the ninth bit for transmission when the UART is operating with nine data bits per frame. There is no parity selection in this framing format. For other framing formats XBIT9 is not needed and the bit is PSEL0 used in conjunction with PSEL1 to select parity.

The frame formats for the receiver differ from the transmitter in the number of Stop bits required. The receiver only requires one Stop bit in a frame, regardless of the setting of the Stop bit selection bits in the control register. Note that an implicit assumption is made for full duplex UART operation that the framing formats are the same for the transmitter and receiver.

UART Operation (Continued)

TL/DD/11214-24

FIGURE 12. Framing Formats

UART INTERRUPTS

The UART is capable of generating interrupts. Interrupts are generated on Receive Buffer Full and Transmit Buffer Empty. Both interrupts have individual interrupt vectors. Two bytes of program memory space are reserved for each interrupt vector. The two vectors are located at addresses 0xEC to 0xEF Hex in the program memory space. The interrupts can be individually enabled or disabled using Enable Transmit Interrupt (ETI) and Enable Receive Interrupt (ERI) bits in the ENUI register.

The interrupt from the Transmitter is set pending, and remains pending, as long as both the TBMT and ETI bits are set. To remove this interrupt, software must either clear the ETI bit or write to the TBUF register (thus clearing the TBMT bit).

The interrupt from the receiver is set pending, and remains pending, as long as both the RBFL and ERI bits are set. To remove this interrupt, software must either clear the ERI bit or read from the RBUF register (thus clearing the RBFL bit).

Baud Clock Generation

The clock inputs to the transmitter and receiver sections of the UART can be individually selected to come either from an external source at the CKX pin (port L, pin L1) or from a

source selected in the PSR and BAUD registers. Internally, the basic baud clock is created from the oscillator frequency through a two-stage divider chain consisting of a 1-16 (increments of 0.5) prescaler and an 11-bit binary counter. (Figure 13) The divide factors are specified through two read/write registers shown in Figure 14. Note that the 11-bit Baud Rate Divisor spills over into the Prescaler Select Register (PSR). PSR is cleared upon reset.

As shown in Table I, a Prescaler Factor of 0 corresponds to NO CLOCK. NO CLOCK condition is the UART power down mode where the UART clock is turned off for power saving purpose. The user must also turn the UART clock off when a different baud rate is chosen.

The correspondences between the 5-bit Prescaler Select and Prescaler factors are shown in Table I. There are many ways to calculate the two divisor factors, but one particularly effective method would be to achieve a 1.8432 MHz frequency coming out of the first stage. The 1.8432 MHz prescaler output is then used to drive the software programmable baud rate counter to create a x16 clock for the following baud rates: 110, 134.5, 150, 300, 600, 1200, 1800, 2400, 3600, 4800, 7200, 9600, 19200 and 38400 (Table II). Other baud rates may be created by using appropriate divisors. The x16 clock is then divided by 16 to provide the rate for the serial shift registers of the transmitter and receiver.

TABLE II. Baud Rate Divisors
(1.8432 MHz Prescaler Output)

Baud Rate	Baud Rate Divisor - 1 (N-1)
110 (110.03)	1046
134.5 (134.58)	855
150	767
300	383
600	191
1200	95
1800	63
2400	47
3600	31
4800	23
7200	15
9600	11
19200	5
38400	2

The entries in Table II assume a prescaler output of 1.8432 MHz. In the asynchronous mode the baud rate could be as high as 625k.

As an example, considering the Asynchronous Mode and a CKI clock of 4.608 MHz, the prescaler factor selected is:

$$4.608 / 1.8432 = 2.5$$

The 2.5 entry is available in Table I. The 1.8432 MHz prescaler output is then used with proper Baud Rate Divisor (Table II) to obtain different baud rates. For a baud rate of 19200 e.g., the entry in Table II is 5.

$$N - 1 = 5 \text{ (N - 1 is the value from Table II)}$$

$$N = 6 \text{ (N is the Baud Rate Divisor)}$$

$$\text{Baud Rate} = 1.8432 \text{ MHz} / (16 \times 6) = 19200$$

The divide by 16 is performed because in the asynchronous mode, the input frequency to the UART is 16 times the baud rate. The equation to calculate baud rates is given below.

The actual Baud Rate may be found from:

$$BR = Fc / (16 \times N \times P)$$

Baud Clock Generation (Continued)

Where:

BR is the Baud Rate

Fc is the CKI frequency

N is the Baud Rate Divisor (Table II).

P is the Prescaler Divide Factor selected by the value in the Prescaler Select Register (Table I)

Note: In the Synchronous Mode, the divisor 16 is replaced by two.

Example:

Asynchronous Mode:

$$\text{Crystal Frequency} = 5 \text{ MHz}$$

$$\text{Desired baud rate} = 9600$$

Using the above equation $N \times P$ can be calculated first.

$$N \times P = (5 \times 10^6) / (16 \times 9600) = 32.552$$

Now 32.552 is divided by each Prescaler Factor (Table II) to obtain a value closest to an integer. This factor happens to be 6.5 ($P = 6.5$).

$$N = 32.552 / 6.5 = 5.008 \quad (N = 5)$$

The programmed value (from Table II) should be 4 ($N - 1$).

Using the above values calculated for N and P:

$$BR = (5 \times 10^6) / (16 \times 5 \times 6.5) = 9615.384$$

$$\% \text{ error} = (9615.385 - 9600) / 9600 = 0.16$$

Effect of HALT/IDLE

The UART logic is reinitialized when either the HALT or IDLE modes are entered. This reinitialization sets the TBMT flag and resets all read only bits in the UART control and status registers. Read/Write bits remain unchanged. The Transmit Buffer (TBUF) is not affected, but the Transmit Shift register (TSFT) bits are set to one. The receiver registers RBUF and RSFT are not affected.

The device will exit from the HALT/IDLE modes when the Start bit of a character is detected at the RDX (L3) pin. This feature is obtained by using the Multi-Input Wakeup scheme provided on the device.

Before entering the HALT or IDLE modes the user program must select the Wakeup source to be on the RDX pin. This selection is done by setting bit 3 of WKEN (Wakeup Enable) register. The Wakeup trigger condition is then selected to be high to low transition. This is done via the WKEDG register (Bit 3 is zero.)

If the device is halted and crystal oscillator is used, the Wakeup signal will not start the chip running immediately because of the finite start up time requirement of the crystal oscillator. The idle timer (T0) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the device to execute code. The user has to consider this delay when data transfer is expected immediately after exiting the HALT mode.

Diagnostic

Bits CHARL0 and CHARL1 in the ENU register provide a loopback feature for diagnostic testing of the UART. When these bits are set to one, the following occur: The receiver input pin (RDX) is internally connected to the transmitter output pin (TDX); the output of the Transmitter Shift Register is "looped back" into the Receive Shift Register input. In this mode, data that is transmitted is immediately received. This feature allows the processor to verify the transmit and receive data paths of the UART.

Note that the framing format for this mode is the nine bit format; one Start bit, nine data bits, and 7/8, one or two Stop bits. Parity is not generated or verified in this mode.

Attention Mode

The UART Receiver section supports an alternate mode of operation, referred to as ATTENTION Mode. This mode of operation is selected by the ATTN bit in the ENUR register. The data format for transmission must also be selected as having nine Data bits and either 7/8, one or two Stop bits.

The ATTENTION mode of operation is intended for use in networking the device with other processors. Typically in such environments the messages consists of device addresses, indicating which of several destinations should receive them, and the actual data. This Mode supports a scheme in which addresses are flagged by having the ninth bit of the data field set to a 1. If the ninth bit is reset to a zero the byte is a Data byte.

While in ATTENTION mode, the UART monitors the communication flow, but ignores all characters until an address character is received. Upon receiving an address character, the UART signals that the character is ready by setting the RBFL flag, which in turn interrupts the processor if UART Receiver interrupts are enabled. The ATTN bit is also cleared automatically at this point, so that data characters as well as address characters are recognized. Software examines the contents of the RBUF and responds by deciding either to accept the subsequent data stream (by leaving the ATTN bit reset) or to wait until the next address character is seen (by setting the ATTN bit again).

Operation of the UART Transmitter is not affected by selection of this Mode. The value of the ninth bit to be transmitted is programmed by setting XBIT9 appropriately. The value of the ninth bit received is obtained by reading RBIT9. Since this bit is located in ENUR register where the error flags reside, a bit operation on it will reset the error flags.

Comparators

The devices contain two differential comparators, each with a pair of inputs (positive and negative) and an output. Ports I1-I3 and I4-I6 are used for the comparators. The following is the Port I assignment:

- I1 Comparator1 negative input
- I2 Comparator1 positive input
- I3 Comparator1 output
- I4 Comparator2 negative input
- I5 Comparator2 positive input
- I6 Comparator2 output

A Comparator Select Register (CMPSL) is used to enable the comparators, read the outputs of the comparators internally, and enable the outputs of the comparators to the pins. Two control bits (enable and output enable) and one result bit are associated with each comparator. The comparator result bits (CMP1RD and CMP2RD) are read only bits which will read as zero if the associated comparator is not enabled. The Comparator Select Register is cleared with reset, resulting in the comparators being disabled. The comparators should also be disabled before entering either the HALT or IDLE modes in order to save power. The configuration of the CMPSL register is as follows:

Comparators (Continued)

CMPSL REGISTER (ADDRESS X'00B7)

The CMPSL register contains the following bits:

- CMP1EN Enable comparator 1
- CMP1RD Comparator 1 result (this is a read only bit, which will read as 0 if the comparator is not enabled)
- CMP10E Selects pin I3 as comparator 1 output provided that CMPIEN is set to enable the comparator
- CMP2EN Enable comparator 2
- CMP2RD Comparator 2 result (this is a read only bit, which will read as 0 if the comparator is not enabled)
- CMP20E Selects pin I6 as comparator 2 output provided that CMP2EN is set to enable the comparator

Unused	CMP20E	CMP2RD	CMP2EN	CMP10E	CMP1RD	CMP1EN	Unused
--------	--------	--------	--------	--------	--------	--------	--------

Bit 7

Bit 0

Note that the two unused bits of CMPSL may be used as software flags.

Comparator outputs have the same spec as Ports L and G except that the rise and fall times are symmetrical.

Interrupts

The devices support a vectored interrupt scheme. It supports a total of fourteen interrupt sources. The following table lists all the possible device interrupt sources, their arbitration ranking and the memory locations reserved for the interrupt vector for each source.

Two bytes of program memory space are reserved for each interrupt source. All interrupt sources except the software interrupt are maskable. Each of the maskable interrupts have an Enable bit and a Pending bit. A maskable interrupt is active if its associated enable and pending bits are set. If GIE = 1 and an interrupt is active, then the processor will be interrupted as soon as it is ready to start executing an instruction except if the above conditions happen during the Software Trap service routine. This exception is described in the Software Trap sub-section.

The interruption process is accomplished with the INTR instruction (opcode 00), which is jammed inside the Instruction Register and replaces the opcode about to be executed. The following steps are performed for every interrupt:

1. The GIE (Global Interrupt Enable) bit is reset.
2. The address of the instruction about to be executed is pushed into the stack.
3. The PC (Program Counter) branches to address 00FF. This procedure takes 7 t_c cycles to execute.

FIGURE 15. Interrupt Block Diagram

TL/DD/11214-27

Interrupts (Continued)

Arbitration Ranking	Source	Description	Vector Address Hi-Low Byte
(1) Highest	Software	INTR Instruction	0yFE–0yFF
	Reserved	for Future Use	0yFC–0yFD
(2)	External	Pin G0 Edge	0yFA–0yFB
(3)	Timer T0	Underflow	0yF8–0yF9
(4)	Timer T1	T1A/Underflow	0yF6–0yF7
(5)	Timer T1	T1B	0yF4–0yF5
(6)	MICROWIRE/PLUS	BUSY Goes Low	0yF2–0yF3
	Reserved	for Future Use	0yF0–0yF1
(7)	UART	Receive	0yEE–0yEF

(9)	Timer T2	T2A/Underflow	0yEA–0yEB
(10)	Timer T2	T2B	0yE8–0yE9
(11)	Timer T3	T3A/Underflow	0yE6–0yE7
(12)	Timer T3	T3B	0yE4–0yE5
(13)	Port L/Wakeup	Port L Edge	0yE2–0yE3
(14) Lowest	Default	VIS Instr. Execution without Any Interrupts	0yE0–0yE1

y is VIS page, y ≠ 0.

At this time, since $GIE = 0$, other maskable interrupts are disabled. The user is now free to do whatever context switching is required by saving the context of the machine in the stack with PUSH instructions. The user would then program a VIS (Vector Interrupt Select) instruction in order to branch to the interrupt service routine of the highest priority interrupt enabled and pending at the time of the VIS. Note that this is not necessarily the interrupt that caused the branch to address location 00FF Hex prior to the context switching.

Thus, if an interrupt with a higher rank than the one which caused the interruption becomes active before the decision of which interrupt to service is made by the VIS, then the interrupt with the higher rank will override any lower ones and will be acknowledged. The lower priority interrupt(s) are still pending, however, and will cause another interrupt immediately following the completion of the interrupt service routine associated with the higher priority interrupt just serviced. This lower priority interrupt will occur immediately following the RETI (Return from Interrupt) instruction at the end of the interrupt service routine just completed.

Inside the interrupt service routine, the associated pending bit has to be cleared by software. The RETI (Return from Interrupt) instruction at the end of the interrupt service routine will set the GIE (Global Interrupt Enable) bit, allowing the processor to be interrupted again if another interrupt is active and pending.

The VIS instruction looks at all the active interrupts at the time it is executed and performs an indirect jump to the beginning of the service routine of the one with the highest rank.

The addresses of the different interrupt service routines, called vectors, are chosen by the user and stored in ROM in a table starting at 01E0 (assuming that VIS is located between 00FF and 01DF). The vectors are 15-bit wide and therefore occupy 2 ROM locations.

VIS and the vector table must be located in the same 256-byte block (0y00 to 0yFF) except if VIS is located at the last address of a block. In this case, the table must be in the next block. The vector table cannot be inserted in the first 256-byte block (y ≠ 0).

The vector of the maskable interrupt with the lowest rank is located at 0yE0 (Hi-Order byte) and 0yE1 (Lo-Order byte) and so forth in increasing rank number. The vector of the maskable interrupt with the highest rank is located at 0yFA (Hi-Order byte) and 0yFB (Lo-Order byte).

The Software Trap has the highest rank and its vector is located at 0yFE and 0yFF.

If, by accident, a VIS gets executed and no interrupt is active, then the PC (Program Counter) will branch to a vector located at 0yE0–0yE1. This vector can point to the Software Trap (ST) interrupt service routine, or to another special service routine as desired.

Figure 15 shows the Interrupt block diagram.

SOFTWARE TRAP

The Software Trap (ST) is a special kind of non-maskable interrupt which occurs when the INTR instruction (used to acknowledge interrupts) is fetched from ROM and placed inside the instruction register. This may happen when the PC is pointing beyond the available ROM address space or when the stack is over-popped.

Interrupts (Continued)

When an ST occurs, the user can re-initialize the stack pointer and do a recovery procedure (similar to reset, but not necessarily containing all of the same initialization procedures) before restarting.

The occurrence of an ST is latched into the ST pending bit. The GIE bit is not affected and the ST pending bit (**not accessible by the user**) is used to inhibit other interrupts and to direct the program to the ST service routine with the VIS instruction. The RPND instruction is used to clear the software interrupt pending bit. This pending bit is also cleared on reset.

The ST has the highest rank among all interrupts.

Nothing (except another ST) can interrupt an ST being serviced.

WATCHDOG

The devices contain a WATCHDOG and clock monitor. The WATCHDOG is designed to detect the user program getting stuck in infinite loops resulting in loss of program control or "runaway" programs. The Clock Monitor is used to detect the absence of a clock or a very slow clock below a specified rate on the CKI pin.

The WATCHDOG consists of two independent logic blocks: WD UPPER and WD LOWER. WD UPPER establishes the upper limit on the service window and WD LOWER defines the lower limit of the service window.

Servicing the WATCHDOG consists of writing a specific value to a WATCHDOG Service Register named WDSVR which is memory mapped in the RAM. This value is composed of three fields, consisting of a 2-bit Window Select, a 5-bit Key Data field, and the 1-bit Clock Monitor Select field. Table III shows the WDSVR register.

The lower limit of the service window is fixed at 2048 instruction cycles. Bits 7 and 6 of the WDSVR register allow the user to pick an upper limit of the service window.

Table IV shows the four possible combinations of lower and upper limits for the WATCHDOG service window. This flexibility in choosing the WATCHDOG service window prevents any undue burden on the user software.

Bits 5, 4, 3, 2 and 1 of the WDSVR register represent the 5-bit Key Data field. The key data is fixed at 01100. Bit 0 of the WDSVR Register is the Clock Monitor Select bit.

TABLE III. WATCHDOG Service Register (WDSVR)

Window Select		Key Data					Clock Monitor
X	X	0	1	1	0	0	Y
7	6	5	4	3	2	1	0

TABLE IV. WATCHDOG Service Window Select

WDSVR Bit 7	WDSVR Bit 6	Service Window (Lower-Upper Limits)
0	0	2k–8k t_c Cycles
0	1	2k–16k t_c Cycles
1	0	2k–32k t_c Cycles
1	1	2k–64k t_c Cycles

Clock Monitor

The Clock Monitor aboard the device can be selected or deselected under program control. The Clock Monitor is guaranteed not to reject the clock if the instruction cycle clock ($1/t_c$) is greater or equal to 10 kHz. This equates to a clock input rate on CKI of greater or equal to 100 kHz.

WATCHDOG Operation

The WATCHDOG and Clock Monitor are disabled during reset. The device comes out of reset with the WATCHDOG armed, the WATCHDOG Window Select bits (bits 6, 7 of the WDSVR Register) set, and the Clock Monitor bit (bit 0 of the WDSVR Register) enabled. Thus, a Clock Monitor error will occur after coming out of reset, if the instruction cycle clock frequency has not reached a minimum specified value, including the case where the oscillator fails to start.

The WDSVR register can be written to only once after reset and the key data (bits 5 through 1 of the WDSVR Register) must match to be a valid write. This write to the WDSVR register involves two irrevocable choices: (i) the selection of the WATCHDOG service window (ii) enabling or disabling of the Clock Monitor. Hence, the first write to WDSVR Register involves selecting or deselecting the Clock Monitor, select the WATCHDOG service window and match the WATCHDOG key data. Subsequent writes to the WDSVR register will compare the value being written by the user to the WATCHDOG service window value and the key data (bits 7 through 1) in the WDSVR Register. Table V shows the sequence of events that can occur.

The user must service the WATCHDOG at least once before the upper limit of the service window expires. The WATCHDOG may not be serviced more than once in every lower limit of the service window. The user may service the WATCHDOG as many times as wished in the time period between the lower and upper limits of the service window. The first write to the WDSVR Register is also counted as a WATCHDOG service.

The WATCHDOG has an output pin associated with it. This is the WDOUT pin, on pin 1 of the port G. WDOUT is active low. The WDOUT pin is in the high impedance state in the inactive state. Upon triggering the WATCHDOG, the logic will pull the WDOUT (G1) pin low for an additional 16 t_c –32 t_c cycles after the signal level on WDOUT pin goes below the lower Schmitt trigger threshold. After this delay, the device will stop forcing the WDOUT output low.

The WATCHDOG service window will restart when the WDOUT pin goes high. It is recommended that the user tie the WDOUT pin back to V_{CC} through a resistor in order to pull WDOUT high.

A WATCHDOG service while the WDOUT signal is active will be ignored. The state of the WDOUT pin is not guaranteed on reset, but if it powers up low then the WATCHDOG will time out and WDOUT will enter high impedance state.

The Clock Monitor forces the G1 pin low upon detecting a clock frequency error. The Clock Monitor error will continue until the clock frequency has reached the minimum specified value, after which the G1 output will enter the high impedance TRI-STATE mode following 16 t_c –32 t_c clock cycles. The Clock Monitor generates a continual Clock Monitor error if the oscillator fails to start, or fails to reach the minimum specified frequency. The specification for the Clock Monitor is as follows:

$1/t_c > 10$ kHz—No clock rejection.

$1/t_c < 10$ Hz—Guaranteed clock rejection.

WATCHDOG Operation (Continued)

WATCHDOG AND CLOCK MONITOR SUMMARY

The following salient points regarding the COP888EG WATCHDOG and CLOCK MONITOR should be noted:

- Both the WATCHDOG and CLOCK MONITOR detector circuits are inhibited during RESET.
- Following RESET, the WATCHDOG and CLOCK MONITOR are both enabled, with the WATCHDOG having the maximum service window selected.
- The WATCHDOG service window and CLOCK MONITOR enable/disable option can only be changed once, during the initial WATCHDOG service following RESET.
- The initial WATCHDOG service must match the key data value in the WATCHDOG Service register WDSVR in order to avoid a WATCHDOG error.
- Subsequent WATCHDOG services must match all three data fields in WDSVR in order to avoid WATCHDOG errors.
- The correct key data value cannot be read from the WATCHDOG Service register WDSVR. Any attempt to read this key data value of 01100 from WDSVR will read as key data value of all 0's.
- The WATCHDOG detector circuit is inhibited during both the HALT and IDLE modes.
- The CLOCK MONITOR detector circuit is active during both the HALT and IDLE modes. Consequently, the COP888 inadvertently entering the HALT mode will be detected as a CLOCK MONITOR error (provided that the CLOCK MONITOR enable option has been selected by the program).
- With the single-pin R/C oscillator mask option selected and the CLKDLY bit reset, the WATCHDOG service window will resume following HALT mode from where it left off before entering the HALT mode.
- With the crystal oscillator mask option selected, or with the single-pin R/C oscillator mask option selected and the CLKDLY bit set, the WATCHDOG service window will be set to its selected value from WDSVR following HALT. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following HALT, but must be serviced within the selected window to avoid a WATCHDOG error.
- The IDLE timer T0 is not initialized with RESET.
- The user can sync in to the IDLE counter cycle with an IDLE counter (T0) interrupt or by monitoring the TOPND flag. The TOPND flag is set whenever the thirteenth bit of the IDLE counter toggles (every 4096 instruction cycles). The user is responsible for resetting the TOPND flag.
- A hardware WATCHDOG service occurs just as the device exits the IDLE mode. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following IDLE, but must be serviced within the selected window to avoid a WATCHDOG error.
- Following RESET, the initial WATCHDOG service (where the service window and the CLOCK MONITOR enable/disable must be selected) may be programmed anywhere within the maximum service window (65,536 instruction cycles) initialized by RESET. Note that this initial WATCHDOG service may be programmed within the initial 2048 instruction cycles without causing a WATCHDOG error.

Detection of Illegal Conditions

The device can detect various illegal conditions resulting from coding errors, transient noise, power supply voltage drops, runaway programs, etc.

Reading of undefined ROM gets zeros. The opcode for software interrupt is zero. If the program fetches instructions from undefined ROM, this will force a software interrupt, thus signaling that an illegal condition has occurred.

The subroutine stack grows down for each call (jump to subroutine), interrupt, or PUSH, and grows up for each return or POP. The stack pointer is initialized to RAM location 06F Hex during reset. Consequently, if there are more returns than calls, the stack pointer will point to addresses 070 and 071 Hex (which are undefined RAM). Undefined RAM from addresses 070 to 07F (Segment 0), 140 to 17F (Segment 1), and all other segments (i.e., Segments 3 . . . etc.) is read as all 1's, which in turn will cause the program to return to address 7FFF Hex. This is an undefined ROM location and the instruction fetched (all 0's) from this location will generate a software interrupt signaling an illegal condition.

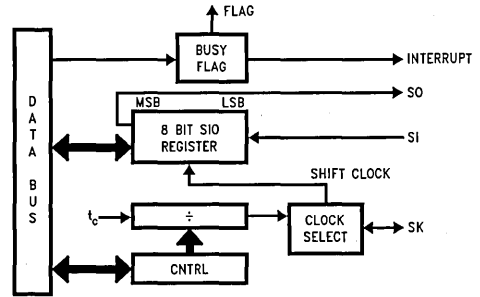

Thus, the chip can detect the following illegal conditions:

- a. Executing from undefined ROM
- b. Over "POP"ing the stack by having more returns than calls.

When the software interrupt occurs, the user can re-initialize the stack pointer and do a recovery procedure before re-starting (this recovery program is probably similar to that following reset, but might not contain the same program initialization procedures). The recovery program should reset the software interrupt pending bit using the RPND instruction.

MICROWIRE/PLUS

MICROWIRE/PLUS is a serial synchronous communications interface. The MICROWIRE/PLUS capability enables the device to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, E²PROMs etc.) and with other microcontrollers which support the MICROWIRE interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 12 shows a block diagram of the MICROWIRE/PLUS logic.

TL/DD/11214-28

FIGURE 16. MICROWIRE/PLUS Block Diagram

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS arrangement with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE/PLUS arrangement with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. In the master mode, the SK clock rate is selected by the two bits, SL0 and SL1, in the CNTRL register. Table VI details the different clock rates that may be selected.

TABLE V. WATCHDOG Service Actions

Key Data	Window Data	Clock Monitor	Action
Match	Match	Match	Valid Service: Restart Service Window
Don't Care	Mismatch	Don't Care	Error: Generate WATCHDOG Output
Mismatch	Don't Care	Don't Care	Error: Generate WATCHDOG Output
Don't Care	Don't Care	Mismatch	Error: Generate WATCHDOG Output

TABLE VI. MICROWIRE/PLUS Master Mode Clock Select

SL1	SL0	SK
0	0	$2 \times t_c$
0	1	$4 \times t_c$
1	x	$8 \times t_c$

Where t_c is the instruction cycle clock

MICROWIRE/PLUS (Continued)

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. If enabled, an interrupt is generated when eight data bits have been shifted. The device may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. Figure 13 shows how two devices, microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangements.

Warning:

The SIO register should only be loaded when the SK clock is low. Loading the SIO register while the SK clock is high will result in undefined data in the SIO register. SK clock is normally low when not shifting.

Setting the BUSY flag when the input SK clock is high in the MICROWIRE/PLUS slave mode may cause the current SK clock for the SIO shift register to be narrow. For safety, the BUSY flag should only be set when the input SK clock is low.

MICROWIRE/PLUS Master Mode Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the device. The MICROWIRE Master always initiates all data exchanges. The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table VII summarizes the bit settings required for Master mode of operation.

MICROWIRE/PLUS Slave Mode Operation

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by setting and resetting the appropriate bit in the Port G configuration register. Table VII summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated.

Alternate SK Phase Operation

The device allows either the normal SK clock or an alternate phase SK clock to shift data in and out of the SIO register. In both the modes the SK is normally low. In the normal mode data is shifted in on the rising edge of the SK clock and the data is shifted out on the falling edge of the SK clock. The SIO register is shifted on each falling edge of the SK clock. In the alternate SK phase operation, data is shifted in on the falling edge of the SK clock and shifted out on the rising edge of the SK clock.

A control flag, SKSEL, allows either the normal SK clock or the alternate SK clock to be selected. Resetting SKSEL causes the MICROWIRE/PLUS logic to be clocked from the normal SK signal. Setting the SKSEL flag selects the alternate SK clock. The SKSEL is mapped into the G6 configuration bit. The SKSEL flag will power up in the reset condition, selecting the normal SK signal.

TABLE VII

This table assumes that the control flag MSEL is set.

G4 (SO) Config. Bit	G5 (SK) Config. Bit	G4 Fun.	G5 Fun.	Operation
1	1	SO	Int. SK	MICROWIRE/PLUS Master
0	1	TRI-STATE	Int. SK	MICROWIRE/PLUS Master
1	0	SO	Ext. SK	MICROWIRE/PLUS Slave
0	0	TRI-STATE	Ext. SK	MICROWIRE/PLUS Slave

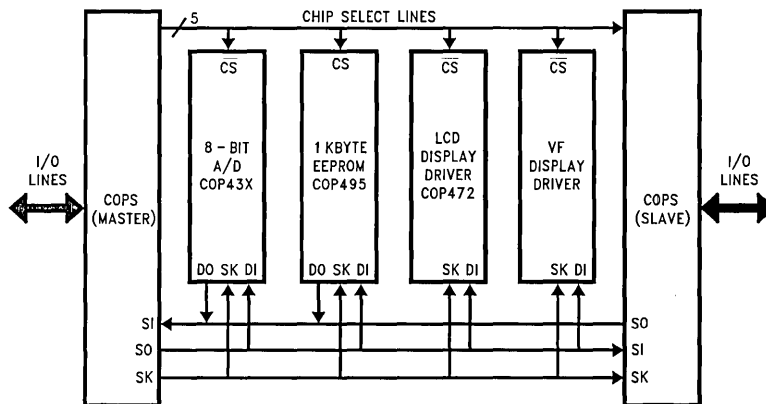

FIGURE 17. MICROWIRE/PLUS Application

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space.

Address S/ADD REG	Contents
0000 to 006F	On-Chip RAM bytes (112 bytes)
0070 to 007F	Unused RAM Address Space (Reads As All Ones)
xx80 to xxAF	Unused RAM Address Space (Reads Undefined Data)
xxB0	Timer T3 Lower Byte
XXB1	Timer T3 Upper Byte
xxB2	Timer T3 Autoload Register T3RA Lower Byte
xxB3	Timer T3 Autoload Register T3RA Upper Byte
xxB4	Timer T3 Autoload Register T3RB Lower Byte
xxB5	Timer T3 Autoload Register T3RB Upper Byte
xxB6	Timer T3 Control Register
xxB7	Comparator Select Register (CMPSL)
xxB8	UART Transmit Buffer (TBUF)
xxB9	UART Receive Buffer (RBUF)
xxBA	UART Control and Status Register (ENU)
xxBB	UART Receive Control and Status Register (ENUR)
xxBC	UART Interrupt and Clock Source Register (ENUI)
xxBD	UART Baud Register (BAUD)
xxBE	UART Prescale Select Register (PSR)
xxBF	Reserved for UART
xxC0	Timer T2 Lower Byte
xxC1	Timer T2 Upper Byte
xxC2	Timer T2 Autoload Register T2RA Lower Byte
xxC3	Timer T2 Autoload Register T2RA Upper Byte
xxC4	Timer T2 Autoload Register T2RB Lower Byte
xxC5	Timer T2 Autoload Register T2RB Upper Byte
xxC6	Timer T2 Control Register
xxC7	WATCHDOG Service Register (Reg:WDSVR)
xxC8	MIWU Edge Select Register (Reg:WKEDG)
xxC9	MIWU Enable Register (Reg:WKEN)
xxCA	MIWU Pending Register (Reg:WKPND)
xxCB	Reserved
xxCC	Reserved
xxCD to xxCF	Reserved

Address S/ADD REG	Contents
xxD0	Port L Data Register
xxD1	Port L Configuration Register
xxD2	Port L Input Pins (Read Only)
xxD3	Reserved for Port L
xxD4	Port G Data Register
xxD5	Port G Configuration Register
xxD6	Port G Input Pins (Read Only)
xxD7	Port I Input Pins (Read Only)
xxD8	Port C Data Register
xxD9	Port C Configuration Register
xxDA	Port C Input Pins (Read Only)
xxDB	Reserved for Port C
xxDC	Port D
xxDD to DF	Reserved for Port D
xxE0 to xxE5	Reserved for EE Control Registers
xxE6	Timer T1 Autoload Register T1RB Lower Byte
xxE7	Timer T1 Autoload Register T1RB Upper Byte
xxE8	ICNTRL Register
xxE9	MICROWIRE/PLUS Shift Register
xxEA	Timer T1 Lower Byte
xxEB	Timer T1 Upper Byte
xxEC	Timer T1 Autoload Register T1RA Lower Byte
xxED	Timer T1 Autoload Register T1RA Upper Byte
xxEE	CNTRL Control Register
xxEF	PSW Register
xxF0 to FB	On-Chip RAM Mapped as Registers
xxFC	X Register
xxFD	SP Register
xxFE	B Register
xxFF	S Register
0100-017F	On-Chip 128 RAM Bytes

Reading memory locations 0070H-007FH (Segment 0) will return all ones. Reading unused memory locations 0080H-00AFH (Segment 0) will return undefined data. Reading memory locations from other Segments (i.e., Segment 2, Segment 3, ... etc.) will return all ones.

Addressing Modes

There are ten addressing modes, six for operand addressing and four for transfer of control.

OPERAND ADDRESSING MODES

Register Indirect

This is the "normal" addressing mode. The operand is the data memory addressed by the B pointer or X pointer.

Register Indirect (with auto post increment or decrement of pointer)

This addressing mode is used with the LD and X instructions. The operand is the data memory addressed by the B pointer or X pointer. This is a register indirect mode that automatically post increments or decrements the B or X register after executing the instruction.

Direct

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

Immediate

The instruction contains an 8-bit immediate field as the operand.

Short Immediate

This addressing mode is used with the Load B Immediate instruction. The instruction contains a 4-bit immediate field as the operand.

Indirect

This addressing mode is used with the LAID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a data operand from the program memory.

TRANSFER OF CONTROL ADDRESSING MODES

Relative

This mode is used for the JP instruction, with the instruction field being added to the program counter to get the new program location. JP has a range from -31 to +32 to allow a 1-byte relative jump (JP + 1 is implemented by a NOP instruction). There are no "pages" when using JP, since all 15 bits of PC are used.

Absolute

This mode is used with the JMP and JSR instructions, with the instruction field of 12 bits replacing the lower 12 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory segment.

Absolute Long

This mode is used with the JMPL and JSRL instructions, with the instruction field of 15 bits replacing the entire 15 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory space.

Indirect

This mode is used with the JID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a location in the program memory. The contents of this program memory location serve as a partial address (lower 8 bits of PC) for the jump to the next instruction.

Note: The VIS is a special case of the Indirect Transfer of Control addressing mode, where the double byte vector associated with the interrupt is transferred from adjacent addresses in the program memory into the program counter (PC) in order to jump to the associated interrupt service routine.

Instruction Set

Register and Symbol Definition

Registers	
A	8-Bit Accumulator Register
B	8-Bit Address Register
X	8-Bit Address Register
SP	8-Bit Stack Pointer Register
PC	15-Bit Program Counter Register
PU	Upper 7 Bits of PC
PL	Lower 8 Bits of PC
C	1 Bit of PSW Register for Carry
HC	1 Bit of PSW Register for Half Carry
GIE	1 Bit of PSW Register for Global Interrupt Enable
VU	Interrupt Vector Upper Byte
VL	Interrupt Vector Lower Byte

Symbols	
[B]	Memory Indirectly Addressed by B Register
[X]	Memory Indirectly Addressed by X Register
MD	Direct Addressed Memory
Mem	Direct Addressed Memory or [B]
Meml	Direct Addressed Memory or [B] or Immediate Data
Imm	8-Bit Immediate Data
Reg	Register Memory: Addresses F0 to FF (Includes B, X and SP)
Bit	Bit Number (0 to 7)
←	Loaded with
↔	Exchanged with

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instructions taking two bytes).

Most single byte instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

Bytes and Cycles per Instruction

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

Where,

i is the immediate data

Md is a directly addressed memory location

* is an unused opcode

Note: The opcode 60 Hex is also the opcode for IFBIT #i,A**Mask Options**

The COP888CG mask programmable options are shown below. The options are programmed at the same time as the ROM pattern submission.

OPTION 1: CLOCK CONFIGURATION

- = 1 Crystal Oscillator (CKI/10)
G7 (CK0) is clock generator output to crystal/resonator
CKI is the clock input
- = 2 Single-pin RC controlled oscillator (CKI/10)
G7 is available as a HALT restart and/or general purpose input

OPTION 2: HALT

- = 1 Enable HALT mode
- = 2 Disable HALT mode

OPTION 3: BONDING OPTIONS

- = 1 44-Pin PLCC
- = 2 40-Pin DIP
- = 3 N/A
- = 4 28-Pin DIP/SO

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (if clock option-1 has been selected). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface or maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bar graph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use window interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC® via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS-232 serial interface cable
MHW-PS3	Power supply 110V/60 MHz
MHW-PS4	Power supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MHW-884EG28D5PC	28 DIP	4.5V-5.5V	COP884EG
MHW-884EG28DWPC	28 DIP	2.5V-6.0V	COP884EG
MHW-888EG40D5PC	40 DIP	4.5V-5.5V	COP888EG
MHW-888EG40DWPC	40 DIP	2.5V-6.0V	COP888EG
MWH-888EG44D5PC	44 PLCC	4.5V-5.5V	COP888EG
MHW-888EG44DWPC	44 PLCC	2.5V-6.0V	COP888EG

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM®, PC-/XT®, PC-AT® or compatible	424410527-001

Development Support (Continued)

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific datasheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code

from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

Single Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP888EGMHXL-X	X = 1: crystal X = 3: R/C	44 LDCC	Multi-Chip Module (MCM), UV erasable	COP888EG
COP888EGMHD-X	X = 1: crystal X = 3: R/C	40 DIP	MCM, UV erasable	COP888EG

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-SCRM-DIP	MCM Scrambler Board for 40 DIP socket	COP888EGMHD
COP8-SCRM-PCC	MCM Scrambler Board for 44 PLCC/LDCC	COP888EGMHXL
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP scrambler board	COP888EGMHD
COP8-PRGM-PCC	Duplicator Board with COP8-SCRM-PCC scrambler board	COP888EGMEL

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 Baud

Set-up: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs., 7 Days

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

COP688CS/COP684CS/COP888CS/COP884CS/ COP988CS/COP984CS Single-Chip microCMOS Microcontroller

General Description

The COP888 family of microcontrollers uses an 8-bit single chip core architecture fabricated with National Semiconductor's M²C²MOS™ process technology. The COP888CS is a member of this expandable 8-bit core processor family of microcontrollers. (Continued)

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μs instruction cycle time
- 4096 bytes on-board ROM
- 192 bytes on-board RAM
- Single supply operation: 2.5V–6V
- Full duplex UART
- One analog comparator
- MICROWIRE/PLUS™ serial I/O
- WATCHDOG™ and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- One 16-bit timer, with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Ten multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Timer (2)
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - UART (2)
 - Default VIS
- Versatile instruction set
- True bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 PLCC or 40 N or 28 N or 28 SOIC
 - 44 PLCC with 39 I/O pins
 - 40 N with 35 I/O pins
 - 28 SO or 28 N, each with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Form factor emulation devices
- Real time emulation and full program debug offered by National's Development Systems
- For other COP800 devices with a UART see COP888CG and COP888EG

FIGURE 1. COP888CS Block Diagram

TL/DD/10830-1

COP688CS/COP684CS/COP888CS/COP884CS/COP988CS/COP984CS

General Description (Continued)

It is a fully static part, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS serial I/O, one 16-bit timer/counter supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), full duplex UART, one comparator, and two power savings modes (HALT and

IDLE), both with a multi-sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The COP888CS operates over a voltage range of 2.5V to 6V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC}) 7V
 Voltage at Any Pin $-0.3V$ to $V_{CC} + 0.3V$
 Total Current into V_{CC} Pin (Source) 100 mA

Total Current out of GND Pin (Sink) 110 mA

Storage Temperature Range $-65^{\circ}C$ to $+140^{\circ}C$

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

Note 5: Parameter sampled but not 100% tested.

Note 6: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V

Note 5: Parameter sampled but not 100% tested.

Note 6: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

FIGURE 3. MICROWIRE/PLUS Timing

Typical Performance Characteristics (-40°C to +85°C)

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The COP888CS contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input (Schmitt trigger inputs on ports L and G), output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. (See the COP888CS memory map for the various addresses associated with the I/O ports.) Figure 4 shows the I/O port configurations for the COP888CS. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

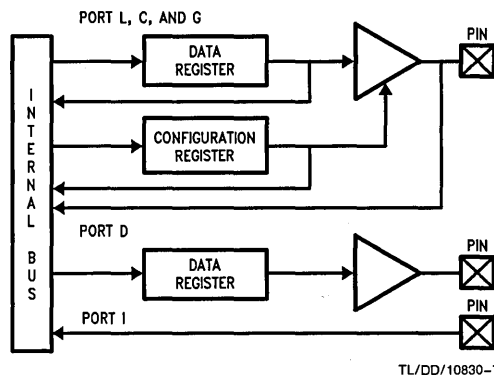

FIGURE 4. I/O Port Configurations

Port L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

The Port L supports Multi-Input Wake Up on all eight pins. L1 is used for the UART external clock. L2 and L3 are used for the UART transmit and receive.

The Port L has the following alternate features:

- L0 MIWU
- L1 MIWU or CKX
- L2 MIWU or TDX
- L3 MIWU or RDX

- L4 MIWU
- L5 MIWU
- L6 MIWU
- L7 MIWU

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOUT WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin but is also used to bring the device out of HALT mode with a low to high transition on G7. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin (crystal clock option) or general purpose input (R/C clock option), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

- G1 WDOUT WATCHDOG and/or Clock Monitor dedicated output
- G7 CKO Oscillator dedicated output or general purpose input

Port C is an 8-bit I/O port. The 40-pin device does not have a full complement of Port C pins. The unavailable pins are not terminated. A read operation for these unterminated pins will return unpredictable values.

Port I is an eight-bit Hi-Z input port. The 28-pin device does not have a full complement of Port I pins. The unavailable

Pin Descriptions (Continued)

pins are not terminated i.e., they are floating. A read operation for these unterminated pins will return unpredictable values. The user must ensure that the software takes this into account by either masking or restricting the accesses to bit operations. The unterminated Port I pins will draw power only when addressed.

Ports I1–I3 are used for Comparator 1.

Ports I1–I3 have the following alternate features.

- I1 COMP1–IN (Comparator 1 Negative Input)
- I2 COMP1+IN (Comparator 1 Positive Input)
- I3 COMP1OUT (Comparator 1 Output)

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Functional Description

The architecture of the COP888CS is modified Harvard architecture. With the Harvard architecture, the control store program memory (ROM) is separated from the data store memory (RAM). Both ROM and RAM have their own separate addressing space with separate address buses. The COP888CS architecture, though based on Harvard architecture, permits transfer of data from ROM to RAM.

CPU REGISTERS

The CPU can do an 8-bit addition, subtraction, logical or shift operation in one instruction (t_c) cycle time.

There are six CPU registers:

A is the 8-bit Accumulator Register

PC is the 15-bit Program Counter Register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is an 8-bit RAM address pointer, which can be optionally post auto incremented or decremented.

X is an 8-bit alternate RAM address pointer, which can be optionally post auto incremented or decremented.

SP is the 8-bit stack pointer, which points to the subroutine/interrupt stack (in RAM). The SP is initialized to RAM address 06F with reset.

S is the 8-bit Data Segment Address Register used to extend the lower half of the address range (00 to 7F) into 256 data segments of 128 bytes each.

All the CPU registers are memory mapped with the exception of the Accumulator (A) and the Program Counter (PC).

PROGRAM MEMORY

Program memory for the COP888CS consists of 4096 bytes of ROM. These bytes may hold program instructions or constant data (data tables for the LAID instruction, jump vectors for the JID instruction, and interrupt vectors for the VIS instruction). The program memory is addressed by the 15-bit program counter (PC). All interrupts in the COP888CS vector to program memory location 0FF Hex.

DATA MEMORY

The data memory address space includes the on-chip RAM and data registers, the I/O registers (Configuration, Data

and Pin), the control registers, the MICROWIRE/PLUS SIO shift register, and the various registers, and counters associated with the timers (with the exception of the IDLE timer). Data memory is addressed directly by the instruction or indirectly by the B, X, SP pointers and S register.

The COP888CS has 192 bytes of RAM. Sixteen bytes of RAM are mapped as "registers" at addresses 0F0 to 0FF Hex. These registers can be loaded immediately, and also decremented and tested with the DRSZ (decrement register and skip if zero) instruction. The memory pointer registers X, SP, B and S are memory mapped into this space at address locations 0FC to 0FF Hex respectively, with the other registers being available for general usage.

The instruction set of the COP888CS permits any bit in memory to be set, reset or tested. All I/O and registers on the COP888CS (except A and PC) are memory mapped; therefore, I/O bits and register bits can be directly and individually set, reset and tested. The accumulator (A) bits can also be directly and individually tested.

Data Memory Segment RAM Extension

Data memory address 0FF is used as a memory mapped location for the Data Segment Address Register (S) in the COP888CS.

The data store memory is either addressed directly by a single byte address within the instruction, or indirectly relative to the reference of the B, X, or SP pointers (each contains a single-byte address). This single-byte address allows an addressing range of 256 locations from 00 to FF hex. The upper bit of this single-byte address divides the data store memory into two separate sections as outlined previously. With the exception of the RAM register memory from address locations 00F0 to 00FF, all RAM memory is memory mapped with the upper bit of the single-byte address being equal to zero. This allows the upper bit of the single-byte address to determine whether or not the base address range (from 0000 to 00FF) is extended. If this upper bit equals one (representing address range 0080 to 00FF), then address extension does not take place. Alternatively, if this upper bit equals zero, then the data segment extension register S is used to extend the base address range (from 0000 to 007F) from XX00 to XX7F, where XX represents the 8 bits from the S register. Thus the 128-byte data segment extensions are located from addresses 0100 to 017F for data segment 1, 0200 to 027F for data segment 2, etc., up to FF00 to FF7F for data segment 255. The base address range from 0000 to 007F represents data segment 0.

Figure 5 illustrates how the S register data memory extension is used in extending the lower half of the base address range (00 to 7F hex) into 256 data segments of 128 bytes each, with a total addressing range of 32 kbytes from XX00 to XX7F. This organization allows a total of 256 data segments of 128 bytes each with an additional upper base segment of 128 bytes. Furthermore, all addressing modes are available for all data segments. The S register must be changed under program control to move from one data segment (128 bytes) to another. However, the upper base segment (containing the 16 memory registers, I/O registers, control registers, etc.) is always available regardless of the

Data Memory Segment RAM Extension (Continued)

contents of the S register, since the upper base segment (address range 0080 to 00FF) is independent of data segment extension.

The instructions that utilize the stack pointer (SP) always reference the stack as part of the base segment (Segment 0), regardless of the contents of the S register. The S register is not changed by these instructions. Consequently, the stack (used with subroutine linkage and interrupts) is always located in the base segment. The stack pointer will be initialized to point at data memory location 006F as a result of reset.

The 128 bytes of RAM contained in the base segment are split between the lower and upper base segments. The first 112 bytes of RAM are resident from address 0000 to 006F in the lower base segment, while the remaining 16 bytes of RAM represent the 16 data memory registers located at addresses 00F0 to 00FF of the upper base segment. No RAM is located at the upper sixteen addresses (0070 to 007F) of the lower base segment.

Additional RAM beyond these initial 128 bytes, however, will always be memory mapped in groups of 128 bytes (or less) at the data segment address extensions (XX00 to XX7F) of the lower base segment. The additional 64 bytes of RAM in the COP888CS (beyond the initial 128 bytes) are memory mapped at address locations 0100 to 013F hex.

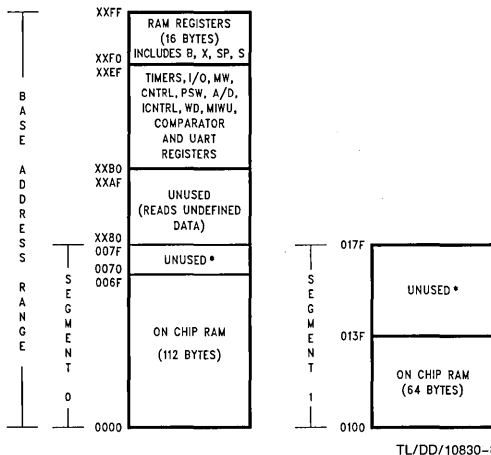

FIGURE 5. RAM Organization

Reset

The RESET input when pulled low initializes the microcontroller. Initialization will occur whenever the RESET input is pulled low. Upon initialization, the data and configuration registers for ports L, G and C are cleared, resulting in these Ports being initialized to the TRI-STATE mode. Pin G1 of the G Port is an exception (as noted below) since pin G1 is dedicated as the WATCHDOG and/or Clock Monitor error output pin. Port D is set high. The PC, PSW, ICNTRL, CNTRL, are cleared. The UART registers PSR, ENU (except that TBMT bit is set), ENUR and ENUI are cleared. The Comparator Select Register is cleared. The S register is initialized to zero. The Multi-Input Wakeup registers WKEN,

WKEDG and WKPND are cleared. The stack pointer, SP, is initialized to 6F Hex.

The COP888CS comes out of reset with both the WATCHDOG logic and the Clock Monitor detector armed, with the WATCHDOG service window bits set and the Clock Monitor bit set. The WATCHDOG and Clock Monitor circuits are inhibited during reset. The WATCHDOG service window bits being initialized high default to the maximum WATCHDOG service window of 64k t_C clock cycles. The Clock Monitor bit being initialized high will cause a Clock Monitor error following reset if the clock has not reached the minimum specified frequency at the termination of reset. A Clock Monitor error will cause an active low error output on pin G1. This error output will continue until 16 t_C –32 t_C clock cycles following the clock frequency reaching the minimum specified value, at which time the G1 output will enter the TRI-STATE mode.

The external RC network shown in Figure 6 should be used to ensure that the RESET pin is held low until the power supply to the chip stabilizes.

TL/DD/10830-9

$RC > 5 \times$ Power Supply Rise Time

FIGURE 6. Recommended Reset Circuit

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_C$).

Figure 7 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table A shows the component values required for various standard crystal values.

R/C OSCILLATOR

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart input.

Table B shows the variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/10830-10

FIGURE 7. Crystal and R/C Oscillator Diagrams

Oscillator Circuits (Continued)

TABLE A. Crystal Oscillator Configuration, $T_A = 25^\circ\text{C}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)	Conditions
0	1	30	30–36	10	$V_{CC} = 5V$
0	1	30	30–36	4	$V_{CC} = 5.0V$

3.3	82	2.2 to 2.7	3.7 to 4.6	$V_{CC} = 5V$
5.6	100	1.1 to 1.3	7.4 to 9.0	$V_{CC} = 5V$
6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5V$

Note: $3k \leq R \leq 200k$
 $50 \text{ pF} \leq C \leq 200 \text{ pF}$

Current Drain

The total current drain of the chip depends on:

- Oscillator operation mode—I1
- Internal switching current—I2
- Internal leakage current—I3
- Output source current—I4
- DC current caused by external input not at V_{CC} or GND—I5
- Comparator DC supply current when enabled—I6
- Clock Monitor current when enabled—I7

Thus the total current drain, I_t , is given as

$$I_t = I_1 + I_2 + I_3 + I_4 + I_5 + I_6 + I_7$$

To reduce the total current drain, each of the above components must be minimum.

The chip will draw more current as the CKI input frequency increases up to the maximum 10 MHz value. Operating with a crystal network will draw more current than an external square-wave. Switching current, governed by the equation below, can be reduced by lowering voltage and frequency. Leakage current can be reduced by lowering voltage and temperature. The other two items can be reduced by carefully designing the end-user's system.

$$I_2 = C \times V \times f$$

where C = equivalent capacitance of the chip
 V = operating voltage
 f = CKI frequency

Control Registers

CNTRL Register (Address X'00EE)

The Timer1 (T1) and MICROWIRE/PLUS control register contains the following bits:

- SL1 & SL0 Select the MICROWIRE/PLUS clock divide by (00 = 2, 01 = 4, 1x = 8)
- IEDG External interrupt edge polarity select (0 = Rising edge, 1 = Falling edge)
- MSEL Selects G5 and G4 as MICROWIRE/PLUS signals SK and SO respectively
- T1C0 Timer T1 Start/Stop control in timer modes 1 and 2
 Timer T1 Underflow Interrupt Pending Flag in timer mode 3
- T1C1 Timer T1 mode control bit
- T1C2 Timer T1 mode control bit
- T1C3 Timer T1 mode control bit

------	------	------	------	------	------	-----	-----

Bit 7

Bit 0

PSW Register (Address X'00EF)

The PSW register contains the following select bits:

- GIE Global interrupt enable (enables interrupts)
- EXEN Enable external interrupt
- BUSY MICROWIRE/PLUS busy shifting flag
- EXPND External interrupt pending
- T1ENA Timer T1 Interrupt Enable for Timer Underflow or T1A Input capture edge
- T1PNDA Timer T1 Interrupt Pending Flag (Autoreload RA in mode 1, T1 Underflow in Mode 2, T1A capture edge in mode 3)
- C Carry Flag
- HC Half Carry Flag

HC	C	T1PNDA	T1ENA	EXPND	BUSY	EXEN	GIE
----	---	--------	-------	-------	------	------	-----

Bit 7

Bit 0

The Half-Carry bit is also affected by all the instructions that affect the Carry flag. The SC (Set Carry) and RC (Reset Carry) instructions will respectively set or clear both the carry flags. In addition to the SC and RC instructions, ADC, SUBC, RRC and RLC instructions affect the carry and Half Carry flags.

Control Registers (Continued)

ICNTRL Register (Address X'00E8)

The ICNTRL register contains the following bits:

T1ENB	Timer T1 Interrupt Enable for T1B Input capture edge
T1PNDB	Timer T1 Interrupt Pending Flag for T1B capture edge
μ WEN	Enable MICROWIRE/PLUS interrupt
μ WPND	MICROWIRE/PLUS interrupt pending
T0EN	Timer T0 Interrupt Enable (Bit 12 toggle)
T0PND	Timer T0 Interrupt pending
LPEN	L Port Interrupt Enable (Multi-Input Wakeup/Interrupt)

Bit 7 could be used as a flag

Unused	LPEN	T0PND	T0EN	μ WPND	μ WEN	T1PNDB	T1ENB	
Bit 7								Bit 0

Timers

The COP888CS contains a very versatile set of timers (T0, T1). All timers and associated autoreload/capture registers power up containing random data.

TIMER T0 (IDLE TIMER)

The COP888CS supports applications that require maintaining real time and low power with the IDLE mode. This IDLE mode support is furnished by the IDLE timer T0, which is a 16-bit timer. The Timer T0 runs continuously at the fixed rate of the instruction cycle clock, t_c . The user cannot read or write to the IDLE Timer T0, which is a count down timer. The Timer T0 supports the following functions:

Exit out of the Idle Mode (See Idle Mode description)

WATCHDOG logic (See WATCHDOG description)

Start up delay out of the HALT mode

The IDLE Timer T0 can generate an interrupt when the thirteenth bit toggles. This toggle is latched into the T0PND pending flag, and will occur every 4 ms at the maximum clock frequency ($t_c = 1 \mu\text{s}$). A control flag T0EN allows the

interrupt from the thirteenth bit of Timer T0 to be enabled or disabled. Setting T0EN will enable the interrupt, while resetting it will disable the interrupt.

TIMER T1

The COP888CS has a powerful timer/counter block.

The timer block consists of a 16-bit timer, T1, and two supporting 16-bit autoreload/capture registers, R1A and R1B. It has two pins associated with it, T1A and T1B. The pin T1A supports I/O required by the timer block, while the pin T1B is an input to the timer block. The powerful and flexible timer block allows the COP888CS to easily perform all timer functions with minimal software overhead. The timer block has three operating modes: Processor Independent PWM mode, External Event Counter mode, and Input Capture mode.

The control bits T1C3, T1C2, and T1C1 allow selection of the different modes of operation.

Mode 1. Processor Independent PWM Mode

As the name suggests, this mode allows the COP888CS to generate a PWM signal with very minimal user intervention.

The user only has to define the parameters of the PWM signal (ON time and OFF time). Once begun, the timer block will continuously generate the PWM signal completely independent of the microcontroller. The user software services the timer block only when the PWM parameters require updating.

In this mode the timer T1 counts down at a fixed rate of t_c . Upon every underflow the timer is alternately reloaded with the contents of supporting registers, R1A and R1B. The very first underflow of the timer causes the timer to reload from the register R1A. Subsequent underflows cause the timer to be reloaded from the registers alternately beginning with the register R1B.

The T1 Timer control bits, T1C3, T1C2 and T1C1 set up the timer for PWM mode operation.

Figure 8 shows a block diagram of the timer in PWM mode. The underflows can be programmed to toggle the T1A output pin. The underflows can also be programmed to generate interrupts.

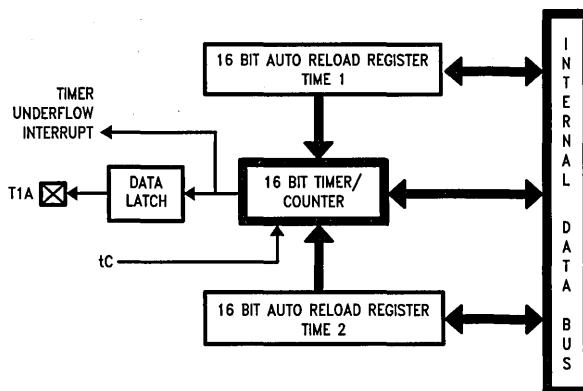

FIGURE 8. Timer in PWM Mode

TL/DD/10830-12

Timers (Continued)

Underflows from the timer are alternately latched into two pending flags, T1PNDA and T1PNDB. The user must reset these pending flags under software control. Two control enable flags, T1ENA and T1ENB, allow the interrupts from the timer underflow to be enabled or disabled. Setting the timer enable flag T1ENA will cause an interrupt when a timer underflow causes the R1A register to be reloaded into the timer. Setting the timer enable flag T1ENB will cause an interrupt when a timer underflow causes the R1B register to be reloaded into the timer. Resetting the timer enable flags will disable the associated interrupts.

Either or both of the timer underflow interrupts may be enabled. This gives the user the flexibility of interrupting once per PWM period on either the rising or falling edge of the PWM output. Alternatively, the user may choose to interrupt on both edges of the PWM output.

Mode 2. External Event Counter Mode

This mode is quite similar to the processor independent PWM mode described above. The main difference is that the timer, T1, is clocked by the input signal from the T1A pin. The Tx timer control bits, T1C3, T1C2 and T1C1 allow the timer to be clocked either on a positive or negative edge from the T1A pin. Underflows from the timer are latched into the T1PNDA pending flag. Setting the T1ENA control flag will cause an interrupt when the timer underflows.

In this mode the input pin T1B can be used as an independent positive edge sensitive interrupt input if the T1ENB control flag is set. The occurrence of a positive edge on the T1B input pin is latched into the T1PNDB flag.

Figure 9 shows a block diagram of the timer in External Event Counter mode.

Note: The PWM output is not available in this mode since the T1A pin is being used as the counter input clock.

Mode 3. Input Capture Mode

The COP888CS can precisely measure external frequencies or time external events by placing the timer block, T1, in the input capture mode.

In this mode, the timer T1 is constantly running at the fixed t_c rate. The two registers, R1A and R1B, act as capture registers. Each register acts in conjunction with a pin. The register R1A acts in conjunction with the T1A pin and the register R1B acts in conjunction with the T1B pin.

The timer value gets copied over into the register when a trigger event occurs on its corresponding pin. Control bits, T1C3, T1C2 and T1C1, allow the trigger events to be specified either as a positive or a negative edge. The trigger condition for each input pin can be specified independently.

The trigger conditions can also be programmed to generate interrupts. The occurrence of the specified trigger condition on the T1A and T1B pins will be respectively latched into the pending flags, T1PNDA and T1PNDB. The control flag T1ENA allows the interrupt on T1A to be either enabled or disabled. Setting the T1ENA flag enables interrupts to be generated when the selected trigger condition occurs on the T1A pin. Similarly, the flag T1ENB controls the interrupts from the T1B pin.

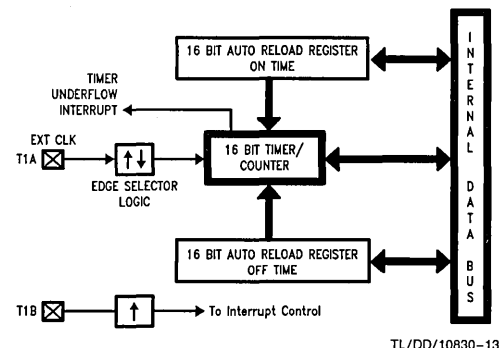

Underflows from the timer can also be programmed to generate interrupts. Underflows are latched into the timer T1C0 pending flag (the T1C0 control bit serves as the timer underflow interrupt pending flag in the Input Capture mode). Consequently, the T1C0 control bit should be reset when entering the Input Capture mode. The timer underflow interrupt is enabled with the T1ENA control flag. When a T1A interrupt occurs in the Input Capture mode, the user must check both the T1PNDA and T1C0 pending flags in order to determine whether a T1A input capture or a timer underflow (or both) caused the interrupt.

Figure 10 shows a block diagram of the timer in Input Capture mode.

TIMER CONTROL FLAGS

The control bits and their functions are summarized below.

- T1C0 Timer Start/Stop control in Modes 1 and 2 (Processor Independent PWM and External Event Counter), where 1 = Start, 0 = Stop
- T1C0 Timer Underflow Interrupt Pending Flag in Mode 3 (Input Capture)
- T1PNDA Timer Interrupt Pending Flag
- T1PNDB Timer Interrupt Pending Flag
- T1ENA Timer Interrupt Enable Flag
- T1ENB Timer Interrupt Enable Flag
1 = Timer Interrupt Enabled
0 = Timer Interrupt Disabled
- T1C3 Timer mode control
- T1C2 Timer mode control
- T1C1 Timer mode control

FIGURE 10. Timer in Input Capture Mode

Timers (Continued)

The timer mode control bits (T1C3, T1C2 and T1C1) are detailed below:

T1C3	T1C2	T1C1	Timer Mode	Interrupt A Source	Interrupt B Source	Timer Counts On
0	0	0	MODE 2 (External Event Counter)	Timer Underflow	Pos. T1B Edge	T1A Pos. Edge
0	0	1	MODE 2 (External Event Counter)	Timer Underflow	Pos. T1B Edge	T1A Neg. Edge
1	0	1	MODE 1 (PWM) T1A Toggle	Autoreload RA	Autoreload RB	t_c
1	0	0	MODE 1 (PWM) No T1A Toggle	Autoreload RA	Autoreload RB	t_c
0	1	0	MODE 3 (Capture) Captures: T1A Pos. Edge T1B Pos. Edge	Pos. T1A Edge or Timer Underflow	Pos. T1B Edge	t_c
1	1	0	MODE 3 (Capture) Captures: T1A Pos. Edge T1B Neg. Edge	Pos. T1A Edge or Timer Underflow	Neg. T1B Edge	t_c
0	1	1	MODE 3 (Capture) Captures: T1A Neg. Edge T1B Pos. Edge	Neg. T1B Edge or Timer Underflow	Pos. T1B Edge	t_c
1	1	1	MODE 3 (Capture) Captures: T1A Neg. Edge T1B Neg. Edge	Neg. T1A Edge or Timer Underflow	Neg. T1B Edge	t_c

Power Save Modes

The COP888CS offers the user two power save modes of operation: HALT and IDLE. In the HALT mode, all microcontroller activities are stopped. In the IDLE mode, the on-board oscillator circuitry the WATCHDOG logic, the Clock Monitor and timer T0 are active but all other microcontroller activities are stopped. In either mode, all on-board RAM, registers, I/O states, and timers (with the exception of T0) are unaltered.

HALT MODE

The COP888CS is placed in the HALT mode by writing a "1" to the HALT flag (G7 data bit). All microcontroller activities, including the clock and timers, are stopped. The WATCHDOG logic on the COP888CS is disabled during the HALT mode. However, the clock monitor circuitry if enabled remains active and will cause the WATCHDOG output pin (WDOUT) to go low. If the HALT mode is used and the user does not want to activate the WDOUT pin, the Clock Monitor should be disabled after the device comes out of reset (resetting the Clock Monitor control bit with the first write to the WDSVR register). In the HALT mode, the power requirements of the COP888CS are minimal and the applied voltage (V_{CC}) may be decreased to V_r ($V_r = 2.0V$) without altering the state of the machine.

The COP888CS supports three different ways of exiting the HALT mode. The first method of exiting the HALT mode is

with the Multi-Input Wakeup feature on the L port. The second method is with a low to high transition on the CKO (G7) pin. This method precludes the use of the crystal clock configuration (since CKO becomes a dedicated output), and so may be used with an RC clock configuration. The third method of exiting the HALT mode is by pulling the RESET pin low.

Since a crystal or ceramic resonator may be selected as the oscillator, the Wakeup signal is not allowed to start the chip running immediately since crystal oscillators and ceramic resonators have a delayed start up time to reach full amplitude and frequency stability. The IDLE timer is used to generate a fixed delay to ensure that the oscillator has indeed stabilized before allowing instruction execution. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry is enabled. The IDLE timer is loaded with a value of 256 and is clocked with the t_c instruction cycle clock. The t_c clock is derived by dividing the oscillator clock down by a factor of 10. The Schmitt trigger following the CKI inverter on the chip ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

Power Save Modes (Continued)

If an RC clock option is being used, the fixed delay is introduced optionally. A control bit, CLKDLY, mapped as configuration bit G7, controls whether the delay is to be introduced or not. The delay is included if CLKDLY is set, and excluded if CLKDLY is reset. The CLKDLY bit is cleared on reset.

The COP888CS has two mask options associated with the HALT mode. The first mask option enables the HALT mode feature, while the second mask option disables the HALT mode. With the HALT mode enable mask option, the COP888CS will enter and exit the HALT mode as described above. With the HALT disable mask option, the COP888CS cannot be placed in the HALT mode (writing a "1" to the HALT flag will have no effect).

The WATCHDOG detector circuit is inhibited during the HALT mode. However, the clock monitor circuit if enabled remains active during HALT mode in order to ensure a clock monitor error if the COP888CS inadvertently enters the HALT mode as a result of a runaway program or power glitch.

IDLE MODE

The COP888CS is placed in the IDLE mode by writing a "1" to the IDLE flag (G6 data bit). In this mode, all activities, except the associated on-board oscillator circuitry, the WATCHDOG logic, the clock monitor and the IDLE Timer T0, are stopped. The power supply requirements of the micro-controller in this mode of operation are typically around 30% of normal power requirement of the microcontroller.

As with the HALT mode, the COP888CS can be returned to normal operation with a reset, or with a Multi-Input Wakeup from the L Port. Alternately, the microcontroller resumes

normal operation from the IDLE mode when the thirteenth bit (representing 4.096 ms at internal clock frequency of 1 MHz, $t_c = 1 \mu\text{s}$) of the IDLE Timer toggles.

This toggle condition of the thirteenth bit of the IDLE Timer T0 is latched into the TOPND pending flag.

The user has the option of being interrupted with a transition on the thirteenth bit of the IDLE Timer T0. The interrupt can be enabled or disabled via the T0EN control bit. Setting the T0EN flag enables the interrupt and vice versa.

The user can enter the IDLE mode with the Timer T0 interrupt enabled. In this case, when the TOPND bit gets set, the COP888CS will first execute the Timer T0 interrupt service routine and then return to the instruction following the "Enter Idle Mode" instruction.

Alternatively, the user can enter the IDLE mode with the IDLE Timer T0 interrupt disabled. In this case, the COP888CS will resume normal operation with the instruction immediately following the "Enter IDLE Mode" instruction.

Note: It is necessary to program two NOP instructions following both the set HALT mode and set IDLE mode instructions. These NOP instructions are necessary to allow clock resynchronization following the HALT or IDLE modes.

Multi-Input Wakeup

The Multi-Input Wakeup feature is used to return (wakeup) the COP888CS from either the HALT or IDLE modes. Alternately Multi-Input Wakeup/Interrupt feature may also be used to generate up to 8 edge selectable external interrupts.

Figure 11 shows the Multi-Input Wakeup logic for the COP888CS microcontroller.

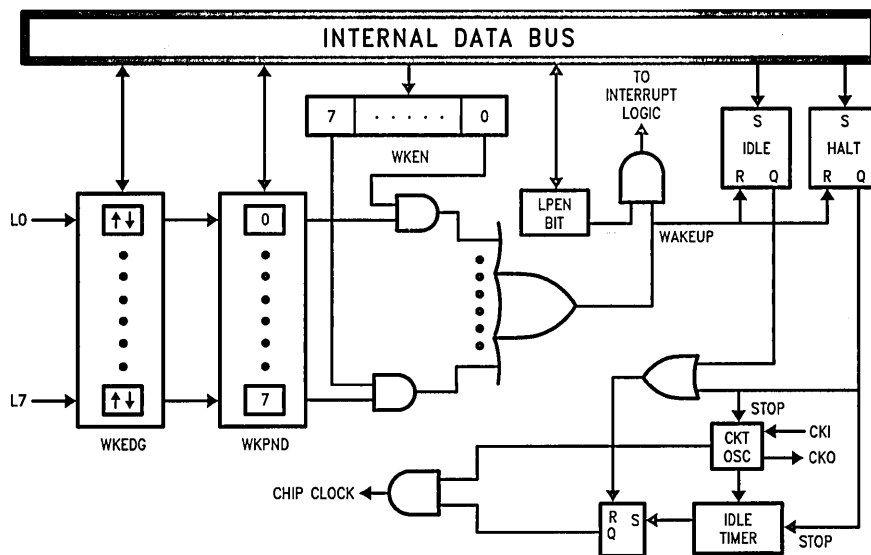

FIGURE 11. Multi-Input Wake Up Logic

TL/DD/10830-15

Multi-Input Wakeup (Continued)

The Multi-Input Wakeup feature utilizes the L Port. The user selects which particular L port bit (or combination of L Port bits) will cause the COP888CS to exit the HALT or IDLE modes. The selection is done through the Reg: WKEN. The Reg: WKEN is an 8-bit read/write register, which contains a control bit for every L port bit. Setting a particular WKEN bit enables a Wakeup from the associated L port pin.

The user can select whether the trigger condition on the selected L Port pin is going to be either a positive edge (low to high transition) or a negative edge (high to low transition). This selection is made via the Reg: WKEDG, which is an 8-bit control register with a bit assigned to each L Port pin. Setting the control bit will select the trigger condition to be a negative edge on that particular L Port pin. Resetting the bit selects the trigger condition to be a positive edge. Changing an edge select entails several steps in order to avoid a pseudo Wakeup condition as a result of the edge change. First, the associated WKEN bit should be reset, followed by the edge select change in WKEDG. Next, the associated WKPND bit should be cleared, followed by the associated WKEN bit being re-enabled.

An example may serve to clarify this procedure. Suppose we wish to change the edge select from positive (low going high) to negative (high going low) for L Port bit 5, where bit 5 has previously been enabled for an input interrupt. The program would be as follows:

```

RBIT 5, WKEN
SBIT 5, WKEDG
RBIT 5, WKPND
SBIT 5, WKEN

```

If the L port bits have been used as outputs and then changed to inputs with Multi-Input Wakeup/Interrupt, a safety procedure should also be followed to avoid inherited pseudo wakeup conditions. After the selected L port bits have been changed from output to input but before the associated WKEN bits are enabled, the associated edge select bits in WKEDG should be set or reset for the desired edge selects, followed by the associated WKPND bits being cleared.

This same procedure should be used following reset, since the L port inputs are left floating as a result of reset.

The occurrence of the selected trigger condition for Multi-Input Wakeup is latched into a pending register called WKPND. The respective bits of the WKPND register will be set on the occurrence of the selected trigger edge on the corresponding Port L pin. The user has the responsibility of clearing these pending flags. Since WKPND is a pending register for the occurrence of selected wakeup conditions, the COP888CS will not enter the HALT mode if any Wakeup bit is both enabled and pending. Consequently, the user has the responsibility of clearing the pending flags before attempting to enter the HALT mode.

WKEN, WKPND and WKEDG are all read/write registers, and are cleared at reset.

PORT L INTERRUPTS

Port L provides the user with an additional eight fully selectable, edge sensitive interrupts which are all vectored into the same service subroutine.

The interrupt from Port L shares logic with the wake up circuitry. The register WKEN allows interrupts from Port L to be individually enabled or disabled. The register WKEDG specifies the trigger condition to be either a positive or a negative edge. Finally, the register WKPND latches in the pending trigger conditions.

The GIE (Global Interrupt Enable) bit enables the interrupt function.

A control flag, LPEN, functions as a global interrupt enable for Port L interrupts. Setting the LPEN flag will enable interrupts and vice versa. A separate global pending flag is not needed since the register WKPND is adequate.

Since Port L is also used for waking the COP888CS out of the HALT or IDLE modes, the user can elect to exit the HALT or IDLE modes either with or without the interrupt enabled. If he elects to disable the interrupt, then the COP888CS will restart execution from the instruction immediately following the instruction that placed the microcontroller in the HALT or IDLE modes. In the other case, the COP888CS will first execute the interrupt service routine and then revert to normal operation.

The Wakeup signal will not start the chip running immediately since crystal oscillators or ceramic resonators have a finite start up time. The IDLE Timer (T0) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the COP888CS to execute instructions. In this case, upon detecting a valid Wakeup signal, only the oscillator circuitry and the IDLE Timer T0 are enabled. The IDLE Timer is loaded with a value of 256 and is clocked from the t_c instruction cycle clock. The t_c clock is derived by dividing down the oscillator clock by a factor of 10. A Schmitt trigger following the CKI on-chip inverter ensures that the IDLE timer is clocked only when the oscillator has a sufficiently large amplitude to meet the Schmitt trigger specifications. This Schmitt trigger is not part of the oscillator closed loop. The startup timeout from the IDLE timer enables the clock signals to be routed to the rest of the chip.

If the RC clock option is used, the fixed delay is under software control. A control flag, CLKDLY, in the G7 configuration bit allows the clock start up delay to be optionally inserted. Setting CLKDLY flag high will cause clock start up delay to be inserted and resetting it will exclude the clock start up delay. The CLKDLY flag is cleared during reset, so the clock start up delay is not present following reset with the RC clock options.

UART

The COP888CS contains a full-duplex software programmable UART. The UART (Figure 12) consists of a transmit shift register, a receiver shift register and seven addressable registers, as follows: a transmit buffer register (TBUF), a receiver buffer register (RBUF), a UART control and status register (ENU), a UART receive control and status register (ENUR), a UART interrupt and clock source register (ENUI), a prescaler select register (PSR) and baud (BAUD) register. The ENU register contains flags for transmit and receive functions; this register also determines the length of the data frame (7, 8 or 9 bits), the value of the ninth bit in transmission, and parity selection bits. The ENUR register flags framing, data overrun and parity errors while the UART is receiving.

Other functions of the ENUR register include saving the ninth bit received in the data frame, enabling or disabling the UART's attention mode of operation and providing additional receiver/transmitter status information via RCVG and XMTG bits. The determination of an internal or external clock source is done by the ENUI register, as well as selecting the number of stop bits and enabling or disabling transmit and receive interrupts. A control flag in this register can also select the UART mode of operation: asynchronous or synchronous.

UART CONTROL AND STATUS REGISTERS

The operation of the UART is programmed through three registers: ENU, ENUR and ENUI. The function of the individual bits in these registers is as follows:

ENU-UART Control and Status Register (Address at 0BA)

PEN	PSEL1	XBIT9/ PSEL0	CHL1	CHL0	ERR	RBFL	TBMT
0RW	0RW	0RW	0RW	0RW	0R	0R	1R

Bit 7 Bit 0

ENUR-UART Receive Control and Status Register (Address at 0BB)

DOE	FE	PE	SPARE	RBIT9	ATTN	XMTG	RCVG
0RD	0RD	0RD	0RW*	0R	0RW	0R	0R

Bit 7 Bit 0

ENUI-UART Interrupt and Clock Source Register (Address at 0BC)

STP2	STP78	ETDX	SSEL	XRCLK	XTCLK	ERI	ETI
0RW	0RW	0RW	0RW	0RW	0RW	0RW	0RW

Bit 7 Bit 0

*Bit is not used.

0 Bit is cleared on reset.

1 Bit is set to one on reset.

R Bit is read-only; it cannot be written by software.

RW Bit is read/write.

D Bit is cleared on read; when read by software as a one, it is cleared automatically. Writing to the bit does not affect its state.

FIGURE 12. UART Block Diagram

TL/DD/10830-16

UART (Continued)**DESCRIPTION OF UART REGISTER BITS****ENU—UART CONTROL AND STATUS REGISTER**

TBMT: This bit is set when the UART transfers a byte of data from the TBUF register into the TSFT register for transmission. It is automatically reset when software writes into the TBUF register.

RBF: This bit is set when the UART has received a complete character and has copied it into the RBUF register. It is automatically reset when software reads the character from RBUF.

ERR: This bit is a global UART error flag which gets set if any or a combination of the errors (DOE, FE, PE) occur.

CHL1, CHL0: These bits select the character frame format. Parity is not included and is generated/verified by hardware.
 CHL1 = 0, CHL0 = 0 The frame contains eight data bits.
 CHL1 = 0, CHL0 = 1 The frame contains seven data bits.
 CHL1 = 1, CHL0 = 0 The frame contains nine data bits.
 CHL1 = 1, CHL0 = 1 Loopback Mode selected. Transmitter output internally looped back to receiver input. Nine bit framing format is used.

XBIT9/PSEL0: Programs the ninth bit for transmission when the UART is operating with nine data bits per frame. For seven or eight data bits per frame, this bit in conjunction with PSEL1 selects parity.

PSEL1, PSEL0: Parity select bits.

PSEL1 = 0, PSEL0 = 0 Odd Parity (if Parity enabled)
 PSEL1 = 0, PSEL0 = 1 Even Parity (if Parity enabled)
 PSEL1 = 1, PSEL0 = 0 Mark(1) (if Parity enabled)
 PSEL1 = 1, PSEL0 = 1 Space(0) (if Parity enabled)

PEN: This bit enables/disables Parity (7- and 8-bit modes only).

PEN = 0 Parity disabled.
 PEN = 1 Parity enabled.

ENUR—UART RECEIVE CONTROL AND STATUS REGISTER

RCVG: This bit is set high whenever a framing error occurs and goes low when RDX goes high.

XMTG: This bit is set to indicate that the UART is transmitting. It gets reset at the end of the last frame (end of last Stop bit).

ATTN: ATTENTION Mode is enabled while this bit is set. This bit is cleared automatically on receiving a character with data bit nine set.

RBIT9: Contains the ninth data bit received when the UART is operating with nine data bits per frame.

SPARE: Reserved for future use.

PE: Flags a Parity Error.

PE = 0 Indicates no Parity Error has been detected since the last time the ENUR register was read.
 PE = 1 Indicates the occurrence of a Parity Error.

FE: Flags a Framing Error.

FE = 0 Indicates no Framing Error has been detected since the last time the ENUR register was read.
 FE = 1 Indicates the occurrence of a Framing Error.

DOE: Flags a Data Overrun Error.

DOE = 0 Indicates no Data Overrun Error has been detected since the last time the ENUR register was read.

DOE = 1 Indicates the occurrence of a Data Overrun Error.

ENUI—UART INTERRUPT AND CLOCK SOURCE REGISTER

ETI: This bit enables/disables interrupt from the transmitter section.

ETI = 0 Interrupt from the transmitter is disabled.
 ETI = 1 Interrupt from the transmitter is enabled.

ERI: This bit enables/disables interrupt from the receiver section.

ERI = 0 Interrupt from the receiver is disabled.
 ERI = 1 Interrupt from the receiver is enabled.

XTCLK: This bit selects the clock source for the transmitter-section.

XTCLK = 0 The clock source is selected through the PSR and BAUD registers.

XTCLK = 1 Signal on CKX (L1) pin is used as the clock.

XRCLK: This bit selects the clock source for the receiver section.

XRCLK = 0 The clock source is selected through the PSR and BAUD registers.

XRCLK = 1 Signal on CKX (L1) pin is used as the clock.

SSEL: UART mode select.

SSEL = 0 Asynchronous Mode.
 SSEL = 1 Synchronous Mode.

ETDX: TDX (UART Transmit Pin) is the alternate function assigned to Port L pin L2; it is selected by setting ETDX bit. To simulate line break generation, software should reset ETDX bit and output logic zero to TDX pin through Port L data and configuration registers.

STP78: This bit is set to program the last Stop bit to be 7/8th of a bit in length.

STP2: This bit programs the number of Stop bits to be transmitted.

STP2 = 0 One Stop bit transmitted.
 STP2 = 1 Two Stop bits transmitted.

Associated I/O Pins

Data is transmitted on the TDX pin and received on the RDX pin. TDX is the alternate function assigned to Port L pin L2; it is selected by setting ETDX (in the ENUI register) to one. RDX is an inherent function of Port L pin L3, requiring no setup.

The baud rate clock for the UART can be generated on-chip, or can be taken from an external source. Port L pin L1 (CKX) is the external clock I/O pin. The CKX pin can be either an input or an output, as determined by Port L Configuration and Data registers (Bit 1). As an input, it accepts a clock signal which may be selected to drive the transmitter and/or receiver. As an output, it presents the internal Baud Rate Generator output.

UART Operation

The UART has two modes of operation: asynchronous mode and synchronous mode.

ASYNCHRONOUS MODE

This mode is selected by resetting the SSEL (in the ENUI register) bit to zero. The input frequency to the UART is 16 times the baud rate.

The TSFT and TBUF registers double-buffer data for transmission. While TSFT is shifting out the current character on the TDX pin, the TBUF register may be loaded by software with the next byte to be transmitted. When TSFT finishes transmitting the current character the contents of TBUF are transferred to the TSFT register and the Transmit Buffer Empty Flag (TBMT in the ENU register) is set. The TBMT flag is automatically reset by the UART when software loads a new character into the TBUF register. There is also the XMTG bit which is set to indicate that the UART is transmitting. This bit gets reset at the end of the last frame (end of last Stop bit). TBUF is a read/write register.

The RSFT and RBUF registers double-buffer data being received. The UART receiver continually monitors the signal on the RDX pin for a low level to detect the beginning of a Start bit. Upon sensing this low level, it waits for half a bit time and samples again. If the RDX pin is still low, the receiver considers this to be a valid Start bit, and the remaining bits in the character frame are each sampled a single time, at the mid-bit position. Serial data input on the RDX pin is shifted into the RSFT register. Upon receiving the complete character, the contents of the RSFT register are copied into the RBUF register and the Received Buffer Full Flag (RBFL) is set. RBFL is automatically reset when software reads the character from the RBUF register. RBUF is a read only register. There is also the RCVG bit which is set high when a framing error occurs and goes low once RDX goes high. TBMT, XMTG, RBFL and RCVG are read only bits.

SYNCHRONOUS MODE

In this mode data is transferred synchronously with the clock. Data is transmitted on the rising edge and received on the falling edge of the synchronous clock.

This mode is selected by setting SSEL bit in the ENUI register. The input frequency to the UART is the same as the baud rate.

When an external clock input is selected at the CKX pin, data transmit and receive are performed synchronously with this clock through TDX/RDX pins.

If data transmit and receive are selected with the CKX pin as clock output, the μ C generates the synchronous clock output at the CKX pin. The internal baud rate generator is used to produce the synchronous clock. Data transmit and receive are performed synchronously with this clock.

FRAMING FORMATS

The UART supports several serial framing formats (*Figure 13*). The format is selected using control bits in the ENU, ENUR and ENUI registers.

The first format (1, 1a, 1b, 1c) for data transmission (CHL0 = 1, CHL1 = 0) consists of Start bit, seven Data bits (excluding parity) and 7/8, one or two Stop bits. In applications using parity, the parity bit is generated and verified by hardware.

The second format (CHL0 = 0, CHL1 = 0) consists of one Start bit, eight Data bits (excluding parity) and 7/8, one or two Stop bits. Parity bit is generated and verified by hardware.

The third format for transmission (CHL0 = 0, CHL1 = 1) consists of one Start bit, nine Data bits and 7/8, one or two Stop bits. This format also supports the UART "ATTENTION" feature. When operating in this format, all eight bits of TBUF and RBUF are used for data. The ninth data bit is transmitted and received using two bits in the ENU and ENUR registers, called XBIT9 and RBIT9. RBIT9 is a read only bit. Parity is not generated or verified in this mode.

For any of the above framing formats, the last Stop bit can be programmed to be 7/8th of a bit in length. If two Stop bits are selected and the 7/8th bit is set (selected), the second Stop bit will be 7/8th of a bit in length.

The parity is enabled/disabled by PEN bit located in the ENU register. Parity is selected for 7- and 8-bit modes only. If parity is enabled (PEN = 1), the parity selection is then performed by PSEL0 and PSEL1 bits located in the ENU register.

Note that the XBIT9/PSEL0 bit located in the ENU register serves two mutually exclusive functions. This bit programs the ninth bit for transmission when the UART is operating with nine data bits per frame. There is no parity selection in this framing format. For other framing formats XBIT9 is not needed and the bit is PSEL0 used in conjunction with PSEL1 to select parity.

The frame formats for the receiver differ from the transmitter in the number of Stop bits required. The receiver only requires one Stop bit in a frame, regardless of the setting of the Stop bit selection bits in the control register. Note that an implicit assumption is made for full duplex UART operation that the framing formats are the same for the transmitter and receiver.

UART Operation (Continued)

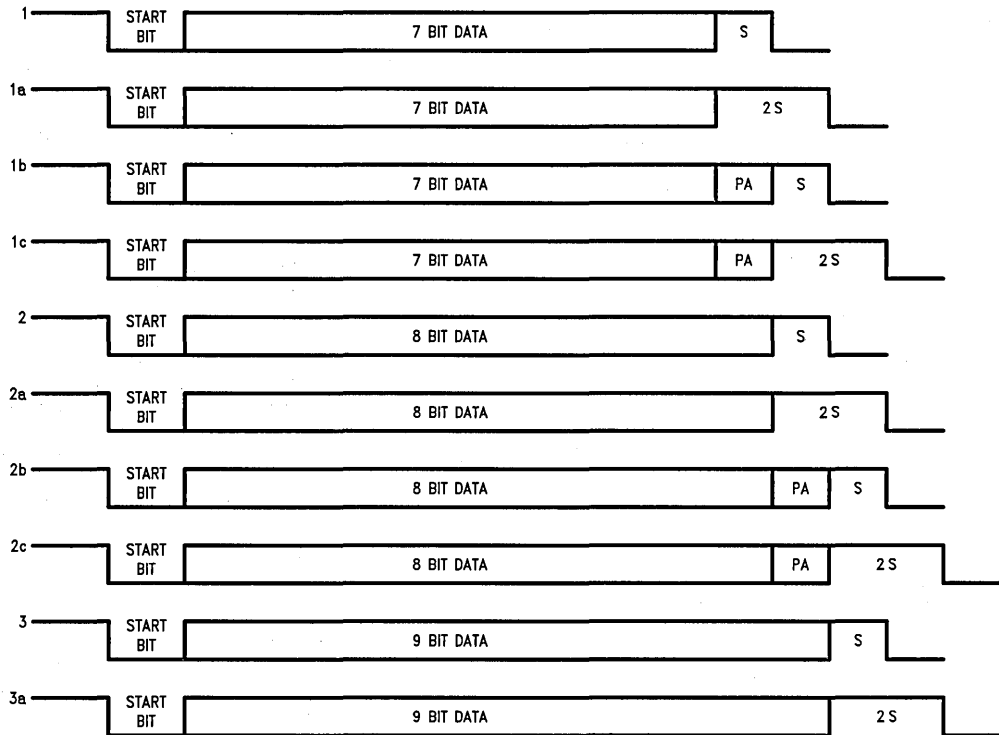

FIGURE 13. Framing Formats

TL/DD/10830-17

UART INTERRUPTS

The UART is capable of generating interrupts. Interrupts are generated on Receive Buffer Full and Transmit Buffer Empty. Both interrupts have individual interrupt vectors. Two bytes of program memory space are reserved for each interrupt vector. The two vectors are located at addresses 0xEC to 0xEF Hex in the program memory space. The interrupts can be individually enabled or disabled using Enable Transmit Interrupt (ETI) and Enable Receive Interrupt (ERI) bits in the ENUI register.

The interrupt from the Transmitter is set pending, and remains pending, as long as both the TBMT and ETI bits are set. To remove this interrupt, software must either clear the ETI bit or write to the TBUF register (thus clearing the TBMT bit).

The interrupt from the receiver is set pending, and remains pending, as long as both the RBFL and ERI bits are set. To remove this interrupt, software must either clear the ERI bit or read from the RBUF register (thus clearing the RBFL bit).

Baud Clock Generation

The clock inputs to the transmitter and receiver sections of the UART can be individually selected to come either from an external source at the CKX pin (port L, pin L1) or from a

source selected in the PSR and BAUD registers. Internally, the basic baud clock is created from the oscillator frequency through a two-stage divider chain consisting of a 1-16 (increments of 0.5) prescaler and an 11-bit binary counter. (Figure 14) The divide factors are specified through two read/write registers shown in Figure 15. Note that the 11-bit Baud Rate Divisor spills over into the Prescaler Select Register (PSR). PSR is cleared upon reset.

As shown in Table I, a Prescaler Factor of 0 corresponds to NO CLOCK. NO CLOCK condition is the UART power down mode where the UART clock is turned off for power saving purpose. The user must also turn the UART clock off when a different baud rate is chosen.

The correspondences between the 5-bit Prescaler Select and Prescaler factors are shown in Table I. There are many ways to calculate the two divisor factors, but one particularly effective method would be to achieve a 1.8432 MHz frequency coming out of the first stage. The 1.8432 MHz prescaler output is then used to drive the software programmable baud rate counter to create a x16 clock for the following baud rates: 110, 134.5, 150, 300, 600, 1200, 1800, 2400, 3600, 4800, 7200, 9600, 19200 and 38400 (Table II). Other baud rates may be created by using appropriate divisors. The x16 clock is then divided by 16 to provide the rate for the serial shift registers of the transmitter and receiver.

TABLE II. Baud Rate Divisors (1.8432 MHz Prescaler Output)

Baud Rate	Baud Rate Divisor - 1 (N-1)
110 (110.03)	1046
134.5 (134.58)	855
150	767
300	383
600	191
1200	95
1800	63
2400	47
3600	31
4800	23
7200	15
9600	11
19200	5
38400	2

The entries in Table II assume a prescaler output of 1.8432 MHz. In the asynchronous mode the baud rate could be as high as 625k.

As an example, considering the Asynchronous Mode and a CKI clock of 4.608 MHz, the prescaler factor selected is:

$$4.608 / 1.8432 = 2.5$$

The 2.5 entry is available in Table I. The 1.8432 MHz prescaler output is then used with proper Baud Rate Divisor (Table II) to obtain different baud rates. For a baud rate of 19200 e.g., the entry in Table II is 5.

$$N - 1 = 5 \text{ (} N - 1 \text{ is the value from Table II)}$$

$$N = 6 \text{ (} N \text{ is the Baud Rate Divisor)}$$

$$\text{Baud Rate} = 1.8432 \text{ MHz} / (16 \times 6) = 19200$$

The divide by 16 is performed because in the asynchronous mode, the input frequency to the UART is 16 times the baud rate. The equation to calculate baud rates is given below.

The actual Baud Rate may be found from:

$$BR = Fc / (16 \times N \times P)$$

Baud Clock Generation (Continued)

Where:

BR is the Baud Rate

Fc is the CKI frequency

N is the Baud Rate Divisor (Table II).

P is the Prescaler Divide Factor selected by the value in the Prescaler Select Register (Table I)

Note: In the Synchronous Mode, the divisor 16 is replaced by two if internal Baud Rate generator is used. Replaced by one if external clock is used.

Example:

Asynchronous Mode:

Crystal Frequency = 5 MHz

Desired baud rate = 9600

Using the above equation $N \times P$ can be calculated first.

$$N \times P = (5 \times 10^6) / (16 \times 9600) = 32.552$$

Now 32.552 is divided by each Prescaler Factor (Table II) to obtain a value closest to an integer. This factor happens to be 6.5 ($P = 6.5$).

$$N = 32.552 / 6.5 = 5.008 \quad (N = 5)$$

The programmed value (from Table II) should be 4 ($N - 1$).

Using the above values calculated for N and P:

$$BR = (5 \times 10^6) / (16 \times 5 \times 6.5) = 9615.384$$

$$\% \text{ error} = (9615.385 - 9600) / 9600 = 0.16$$

Effect of HALT/IDLE

The UART logic is reinitialized when either the HALT or IDLE modes are entered. This reinitialization sets the TBMT flag and resets all read only bits in the UART control and status registers. Read/Write bits remain unchanged. The Transmit Buffer (TBUF) is not affected, but the Transmit Shift register (TSFT) bits are set to one. The receiver registers RBUF and RSFT are not affected.

The μC will exit from the HALT/IDLE modes when the Start bit of a character is detected at the RDX (L3) pin. This feature is obtained by using the Multi-Input Wakeup scheme provided on the μC .

Before entering the HALT or IDLE modes the user program must select the Wakeup source to be on the RDX pin. This selection is done by setting bit 3 of WKEN (Wakeup Enable) register. The Wakeup trigger condition is then selected to be high to low transition. This is done via the WKEDG register (Bit 3 is zero.)

If the microcontroller is halted and crystal oscillator is used, the Wakeup signal will not start the chip running immediately because of the finite start up time requirement of the crystal oscillator. The idle timer (T0) generates a fixed delay to ensure that the oscillator has indeed stabilized before allowing the μC to execute code. The user has to consider this delay when data transfer is expected immediately after exiting the HALT mode.

Diagnostic

Bits CHARL0 and CHARL1 in the ENU register provide a loopback feature for diagnostic testing of the UART. When these bits are set to one, the following occur: The receiver input pin (RDX) is internally connected to the transmitter output pin (TDX); the output of the Transmitter Shift Regis-

ter is "looped back" into the Receive Shift Register input. In this mode, data that is transmitted is immediately received. This feature allows the processor to verify the transmit and receive data paths of the UART.

Note that the framing format for this mode is the nine bit format; one Start bit, nine data bits, and 7/8, one or two Stop bits. Parity is not generated or verified in this mode.

Attention Mode

The UART Receiver section supports an alternate mode of operation, referred to as ATTENTION Mode. This mode of operation is selected by the ATTN bit in the ENUR register. The data format for transmission must also be selected as having nine Data bits and either 7/8, one or two Stop bits.

The ATTENTION mode of operation is intended for use in networking the COP888CS with other processors. Typically in such environments the messages consists of device addresses, indicating which of several destinations should receive them, and the actual data. This Mode supports a scheme in which addresses are flagged by having the ninth bit of the data field set to a 1. If the ninth bit is reset to a zero the byte is a Data byte.

While in ATTENTION mode, the UART monitors the communication flow, but ignores all characters until an address character is received. Upon receiving an address character, the UART signals that the character is ready by setting the RBFL flag, which in turn interrupts the processor if UART Receiver interrupts are enabled. The ATTN bit is also cleared automatically at this point, so that data characters as well as address characters are recognized. Software examines the contents of the RBUF and responds by deciding either to accept the subsequent data stream (by leaving the ATTN bit reset) or to wait until the next address character is seen (by setting the ATTN bit again).

Operation of the UART Transmitter is not affected by selection of this Mode. The value of the ninth bit to be transmitted is programmed by setting XBIT9 appropriately. The value of the ninth bit received is obtained by reading RBIT9. Since this bit is located in ENUR register where the error flags reside, a bit operation on it will reset the error flags.

Comparator

The COP888CS contains one differential comparator, with a pair of inputs (positive and negative) and an output. Ports I1-I3 are used for the comparator. The following is the Port I assignment:

- I1 Comparator1 negative input
- I2 Comparator1 positive input
- I3 Comparator1 output

A Comparator Select Register (CMPSL) is used to enable the comparators, read the outputs of the comparator internally, and enable the output of the comparator to the pins. Two control bits (enable and output enable) and one result bit are associated with the comparator. The comparator result bit (CMP1RD) is read only bit which will read as zero if the comparator is not enabled. The Comparator Select Register is cleared with reset, resulting in the comparator being disabled. The comparator should also be disabled before entering either the HALT or IDLE modes in order to save power. The configuration of the CMPSL register is as follows:

Comparator (Continued)

CMPSL REGISTER (ADDRESS X'00B7)

The CMPSL register contains the following bits:

- CMP1EN Enable comparator 1
- CMP1RD Comparator 1 result (this is a read only bit, which will read as 0 if the comparator is not enabled)
- CMP10E Selects pin I3 as comparator 1 output provided that CMP1EN is set to enable the comparator

Unused	Unused	Unused	Unused	CMP10E	CMP1RD	CMP1EN	Unused
Bit 7				Bit 0			

Comparator outputs have the same spec as Ports L and G except that the rise and fall times are symmetrical.

Interrupts

The COP888CS supports a vectored interrupt scheme. It supports a total of fourteen interrupt sources. The following table lists all the possible COP888CS interrupt sources, their arbitration ranking and the memory locations reserved for the interrupt vector for each source.

Two bytes of program memory space are reserved for each interrupt source. All interrupt sources except the software interrupt are maskable. Each of the maskable interrupts have an Enable bit and a Pending bit. A maskable interrupt is active if its associated enable and pending bits are set. If GIE = 1 and an interrupt is active, then the processor will be interrupted as soon as it is ready to start executing an instruction except if the above conditions happen during the Software Trap service routine. This exception is described in the Software Trap sub-section.

The interruption process is accomplished with the INTR instruction (opcode 00), which is jammed inside the Instruction Register and replaces the opcode about to be executed. The following steps are performed for every interrupt:

1. The GIE (Global Interrupt Enable) bit is reset.
2. The address of the instruction about to be executed is pushed into the stack.
3. The PC (Program Counter) branches to address 00FF. This procedure takes 7 t_c cycles to execute.

At this time, since GIE = 0, other maskable interrupts are disabled. The user is now free to do whatever context switching is required by saving the context of the machine in the stack with PUSH instructions. The user would then program a VIS (Vector Interrupt Select) instruction in order to branch to the interrupt service routine of the highest priority interrupt enabled and pending at the time of the VIS. Note that this is not necessarily the interrupt that caused the branch to address location 00FF Hex prior to the context switching.

Thus, if an interrupt with a higher rank than the one which caused the interruption becomes active before the decision of which interrupt to service is made by the VIS, then the interrupt with the higher rank will override any lower ones and will be acknowledged. The lower priority interrupt(s) are still pending, however, and will cause another interrupt immediately following the completion of the interrupt service routine associated with the higher priority interrupt just serviced. This lower priority interrupt will occur immediately following the RETI (Return from Interrupt) instruction at the end of the interrupt service routine just completed.

Inside the interrupt service routine, the associated pending bit has to be cleared by software. The RETI (Return from Interrupt) instruction at the end of the interrupt service rou-

Arbitration Ranking	Source	Description	Vector Address Hi-Low Byte
(1) Highest	Software	INTR Instruction	0yFE-0yFF
	Reserved	for Future Use	0yFC-0yFD
(2)	External	Pin G0 Edge	0yFA-0yFB
(3)	Timer T0	Underflow	0yF8-0yF9
(4)	Timer T1	T1A/Underflow	0yF6-0yF7
(5)	Timer T1	T1B	0yF4-0yF5
(6)	MICROWIRE/PLUS	BUSY Goes Low	0yF2-0yF3
	Reserved	for Future Use	0yF0-0yF1
(7)	UART	Receive	0yEE-0yEF
(8)	UART	Transmit	0yEC-0yED
(9)	Reserved		0yEA-0yEB
(10)	Reserved		0yE8-0yE9
(11)	Reserved		0yE6-0yE7
(12)	Reserved		0yE4-0yE5
(13)	Port L/Wakeup	Port L Edge	0yE2-0yE3
(14) Lowest	Default	VIS Instr. Execution without Any Interrupts	0yE0-0yE1

y is VIS page, y ≠ 0.

Interrupts (Continued)

tine will set the GIE (Global Interrupt Enable) bit, allowing the processor to be interrupted again if another interrupt is active and pending.

The VIS instruction looks at all the active interrupts at the time it is executed and performs an indirect jump to the beginning of the service routine of the one with the highest rank.

The addresses of the different interrupt service routines, called vectors, are chosen by the user and stored in ROM in a table starting at 01E0 (assuming that VIS is located between 00FF and 01DF). The vectors are 15-bit wide and therefore occupy 2 ROM locations.

VIS and the vector table must be located in the same 256-byte block (0y00 to 0yFF) except if VIS is located at the last address of a block. In this case, the table must be in the next block. The vector table cannot be inserted in the first 256-byte block ($y \neq 0$).

The vector of the maskable interrupt with the lowest rank is located at 0yE0 (Hi-Order byte) and 0yE1 (Lo-Order byte) and so forth in increasing rank number. The vector of the maskable interrupt with the highest rank is located at 0yFA (Hi-Order byte) and 0yFB (Lo-Order byte).

The Software Trap has the highest rank and its vector is located at 0yFE and 0yFF.

If, by accident, a VIS gets executed and no interrupt is active, then the PC (Program Counter) will branch to a vector located at 0yE0–0yE1. This vector can point to the Software Trap (ST) interrupt service routine, or to another special service routine as desired.

Figure 16 shows the COP888CS Interrupt block diagram.

SOFTWARE TRAP

The Software Trap (ST) is a special kind of non-maskable interrupt which occurs when the INTR instruction (used to acknowledge interrupts) is fetched from ROM and placed inside the instruction register. This may happen when the PC is pointing beyond the available ROM address space or when the stack is over-popped.

When an ST occurs, the user can re-initialize the stack pointer and do a recovery procedure (similar to reset, but not necessarily containing all of the same initialization procedures) before restarting.

The occurrence of an ST is latched into the ST pending bit. The GIE bit is not affected and the ST pending bit (**not accessible by the user**) is used to inhibit other interrupts and to direct the program to the ST service routine with the VIS instruction. The RPND instruction is used to clear the software interrupt pending bit. This pending bit is also cleared on reset.

The ST has the highest rank among all interrupts.

Nothing (except another ST) can interrupt an ST being serviced.

WATCHDOG

The COP888CS contains a WATCHDOG and clock monitor. The WATCHDOG is designed to detect the user program getting stuck in infinite loops resulting in loss of program control or "runaway" programs. The Clock Monitor is used to detect the absence of a clock or a very slow clock below a specified rate on the CKI pin.

The WATCHDOG consists of two independent logic blocks: WD UPPER and WD LOWER. WD UPPER establishes the upper limit on the service window and WD LOWER defines the lower limit of the service window.

Servicing the WATCHDOG consists of writing a specific value to a WATCHDOG Service Register named WDSVR which is memory mapped in the RAM. This value is composed of three fields, consisting of a 2-bit Window Select, a 5-bit Key Data field, and the 1-bit Clock Monitor Select field. Table III shows the WDSVR register.

The lower limit of the service window is fixed at 2048 instruction cycles. Bits 7 and 6 of the WDSVR register allow the user to pick an upper limit of the service window.

FIGURE 16. COP888CS Interrupt Block Diagram

TL/DD/10830-20

WATCHDOG (Continued)

Table IV shows the four possible combinations of lower and upper limits for the WATCHDOG service window. This flexibility in choosing the WATCHDOG service window prevents any undue burden on the user software.

Bits 5, 4, 3, 2 and 1 of the WDSVR register represent the 5-bit Key Data field. The key data is fixed at 01100. Bit 0 of the WDSVR Register is the Clock Monitor Select bit.

TABLE III. WATCHDOG Service Register (WDSVR)

Window Select		Key Data					Clock Monitor
X	X	0	1	1	0	0	Y
7	6	5	4	3	2	1	0

TABLE IV. WATCHDOG Service Window Select

WDSVR Bit 7	WDSVR Bit 6	Service Window (Lower-Upper Limits)
0	0	2k–8k t_c Cycles
0	1	2k–16k t_c Cycles
1	0	2k–32k t_c Cycles
1	1	2k–64k t_c Cycles

Clock Monitor

The Clock Monitor aboard the COP888CS can be selected or deselected under program control. The Clock Monitor is guaranteed not to reject the clock if the instruction cycle clock ($1/t_c$) is greater or equal to 10 kHz. This equates to a clock input rate on CKI of greater or equal to 100 kHz.

WATCHDOG Operation

The WATCHDOG and Clock Monitor are disabled during reset. The COP888CS comes out of reset with the WATCHDOG armed, the WATCHDOG Window Select bits (bits 6, 7 of the WDSVR Register) set, and the Clock Monitor bit (bit 0 of the WDSVR Register) enabled. Thus, a Clock Monitor error will occur after coming out of reset, if the instruction cycle clock frequency has not reached a minimum specified value, including the case where the oscillator fails to start.

The WDSVR register can be written to only once after reset and the key data (bits 5 through 1 of the WDSVR Register) must match to be a valid write. This write to the WDSVR register involves two irrevocable choices: (i) the selection of the WATCHDOG service window (ii) enabling or disabling of the Clock Monitor. Hence, the first write to WDSVR Register involves selecting or deselecting the Clock Monitor, select the WATCHDOG service window and match the WATCHDOG key data. Subsequent writes to the WDSVR register will compare the value being written by the user to the WATCHDOG service window value and the key data (bits 7 through 1) in the WDSVR Register. Table V shows the sequence of events that can occur.

The user must service the WATCHDOG at least once before the upper limit of the service window expires. The WATCHDOG may not be serviced more than once in every lower limit of the service window. The user may service the WATCHDOG as many times as wished in the time period between the lower and upper limits of the service window. The first write to the WDSVR Register is also counted as a WATCHDOG service.

The WATCHDOG has an output pin associated with it. This is the WDOUT pin, on pin 1 of the port G. WDOUT is active low. The WDOUT pin is in the high impedance state in the inactive state. Upon triggering the WATCHDOG, the logic will pull the WDOUT (G1) pin low for an additional $16 t_c$ – $32 t_c$ cycles after the signal level on WDOUT pin goes below the lower Schmitt trigger threshold. After this delay, the COP888CS will stop forcing the WDOUT output low.

The WATCHDOG service window will restart when the WDOUT pin goes high. It is recommended that the user tie the WDOUT pin back to V_{CC} through a resistor in order to pull WDOUT high.

A WATCHDOG service while the WDOUT signal is active will be ignored. The state of the WDOUT pin is not guaranteed on reset, but if it powers up low then the WATCHDOG will time out and WDOUT will enter high impedance state.

The Clock Monitor forces the G1 pin low upon detecting a clock frequency error. The Clock Monitor error will continue until the clock frequency has reached the minimum specified value, after which the G1 output will enter the high impedance TRI-STATE mode following $16 t_c$ – $32 t_c$ clock cycles. The Clock Monitor generates a continual Clock Monitor error if the oscillator fails to start, or fails to reach the minimum specified frequency. The specification for the Clock Monitor is as follows:

$1/t_c > 10$ kHz—No clock rejection.

$1/t_c < 10$ Hz—Guaranteed clock rejection.

WATCHDOG AND CLOCK MONITOR SUMMARY

The following salient points regarding the COP888 WATCHDOG and CLOCK MONITOR should be noted:

- Both the WATCHDOG and Clock Monitor detector circuits are inhibited during RESET.
- Following RESET, the WATCHDOG and CLOCK MONITOR are both enabled, with the WATCHDOG having the maximum service window selected.
- The WATCHDOG service window and Clock Monitor enable/disable option can only be changed once, during the initial WATCHDOG service following RESET.
- The initial WATCHDOG service must match the key data value in the WATCHDOG Service register WDSVR in order to avoid a WATCHDOG error.
- Subsequent WATCHDOG services must match all three data fields in WDSVR in order to avoid WATCHDOG errors.
- The correct key data value cannot be read from the WATCHDOG Service register WDSVR. Any attempt to read this key data value of 01100 from WDSVR will read as key data value of all 0's.
- The WATCHDOG detector circuit is inhibited during both the HALT and IDLE modes.
- The Clock Monitor detector circuit is active during both the HALT and IDLE modes. Consequently, the COP888 inadvertently entering the HALT mode will be detected as a Clock Monitor error (provided that the Clock Monitor enable option has been selected by the program).
- With the single-pin R/C oscillator mask option selected and the CLKDLY bit reset, the WATCHDOG service window will resume following HALT mode from where it left off before entering the HALT mode.
- With the crystal oscillator mask option selected, or with the single-pin R/C oscillator mask option selected and the CLKDLY bit set, the WATCHDOG service window will

WATCHDOG Operation (Continued)

be set to its selected value from WDSVR following HALT. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following HALT, but must be serviced within the selected window to avoid a WATCHDOG error.

- The IDLE timer T0 is not initialized with RESET.
- The user can sync in to the IDLE counter cycle with an IDLE counter (T0) interrupt or by monitoring the TOPND flag. The TOPND flag is set whenever the thirteenth bit of the IDLE counter toggles (every 4096 instruction cycles). The user is responsible for resetting the TOPND flag.
- A hardware WATCHDOG service occurs just as the COP888 exits the IDLE mode. Consequently, the WATCHDOG should not be serviced for at least 2048 instruction cycles following IDLE, but must be serviced within the selected window to avoid a WATCHDOG error.
- Following RESET, the initial WATCHDOG service (where the service window and the CLOCK MONITOR enable/disable must be selected) may be programmed anywhere within the maximum service window (65,536 instruction cycles) initialized by RESET. Note that this initial WATCHDOG service may be programmed within the initial 2048 instruction cycles without causing a WATCHDOG error.

Detection of Illegal Conditions

The COP888CS can detect various illegal conditions resulting from coding errors, transient noise, power supply voltage drops, runaway programs, etc.

Reading of undefined ROM gets zeros. The opcode for software interrupt is zero. If the program fetches instructions from undefined ROM, this will force a software interrupt, thus signaling that an illegal condition has occurred.

The subroutine stack grows down for each call (jump to subroutine), interrupt, or PUSH, and grows up for each return or POP. The stack pointer is initialized to RAM location 06F Hex during reset. Consequently, if there are more returns than calls, the stack pointer will point to addresses 070 and 071 Hex (which are undefined RAM). Undefined RAM from addresses 070 to 07F (Segment 0), 140 to 17F (Segment 1), and all other segments (i.e., Segments 3 . . . etc.) is read as all 1's, which in turn will cause the program to return to address 7FFF Hex. This is an undefined ROM location and the instruction fetched (all 0's) from this location will generate a software interrupt signaling an illegal condition.

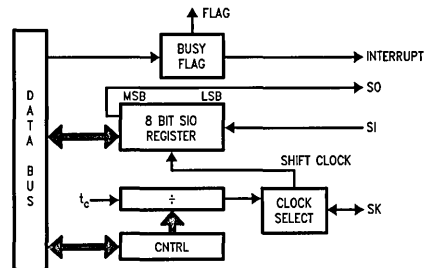

Thus, the chip can detect the following illegal conditions:

- Executing from undefined ROM
- Over "POP"ing the stack by having more returns than calls.

When the software interrupt occurs, the user can re-initialize the stack pointer and do a recovery procedure before re-starting (this recovery program is probably similar to that following reset, but might not contain the same program initialization procedures). The recovery program should reset the software interrupt pending bit using the RPND instruction.

MICROWIRE/PLUS

MICROWIRE/PLUS is a serial synchronous communications interface. The MICROWIRE/PLUS capability enables the COP888CS to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, E²PROMs etc.) and with other microcontrollers which support the MICROWIRE interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 17 shows a block diagram of the MICROWIRE/PLUS logic.

TL/DD/10830-21

FIGURE 17. MICROWIRE/PLUS Block Diagram

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS arrangement with the internal clock source is called the Master mode of operation. Similarly, operating the MICROWIRE/PLUS arrangement with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. In the master mode, the SK clock rate is selected by the two bits, SL0 and SL1, in the CNTRL register. Table VI details the different clock rates that may be selected.

MICROWIRE/PLUS (Continued)

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. If enabled, an interrupt is generated when eight data bits have been shifted. The COP888CS may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. *Figure 14* shows how two COP888CS microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangements.

Warning:

The SIO register should only be loaded when the SK clock is low. Loading the SIO register while the SK clock is high will result in undefined data in the SIO register. SK clock is normally low when not shifting.

Setting the BUSY flag when the input SK clock is high in the MICROWIRE/PLUS slave mode may cause the current SK clock for the SIO shift register to be narrow. For safety, the BUSY flag should only be set when the input SK clock is low.

MICROWIRE/PLUS Master Mode Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the COP888CS. The MICROWIRE Master always initiates all data exchanges. The MSEL bit in the CNTRL register must be set to enable the SO and SK functions onto the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table VII summarizes the bit settings required for Master mode of operation.

MICROWIRE/PLUS Slave Mode Operation

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be selected as an input and the SO pin is selected as an output pin by setting and resetting the appropriate bit in the Port G configuration register. Table VII summarizes the settings required to enter the Slave mode of operation.

The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated.

Alternate SK Phase Operation

The COP888CS allows either the normal SK clock or an alternate phase SK clock to shift data in and out of the SIO register. In both the modes the SK is normally low. In the normal mode data is shifted in on the rising edge of the SK clock and the data is shifted out on the falling edge of the SK clock. The SIO register is shifted on each falling edge of the SK clock in the normal mode. In the alternate SK phase operation, data is shifted in on the falling edge of the SK clock and shifted out on the rising edge of the SK clock.

A control flag, SKSEL, allows either the normal SK clock or the alternate SK clock to be selected. Resetting SKSEL causes the MICROWIRE/PLUS logic to be clocked from the normal SK signal. Setting the SKSEL flag selects the alternate SK clock. The SKSEL is mapped into the G6 configuration bit. The SKSEL flag will power up in the reset condition, selecting the normal SK signal.

TABLE VII

This table assumes that the control flag MSEL is set.

G4 (SO) Config. Bit	G5 (SK) Config. Bit	G4 Fun.	G5 Fun.	Operation
1	1	SO	Int. SK	MICROWIRE/PLUS Master
0	1	TRI-STATE	Int. SK	MICROWIRE/PLUS Master
1	0	SO	Ext. SK	MICROWIRE/PLUS Slave
0	0	TRI-STATE	Ext. SK	MICROWIRE/PLUS Slave

xxFD	SP Register
xxFE	B Register
xxFF	S Register
0100-013F	On-Chip RAM Bytes (64 bytes)

Reading memory locations 0070H-007FH (Segment 0) will return all ones. Reading unused memory locations 0080H-00AFH (Segment 0) will return undefined data. Reading unused memory locations 0140-017F (Segment 1) will return all ones. Reading memory locations from other Segments (i.e., Segment 2, Segment 3, ... etc.) will return all ones.

All reserved location reads undefined data.

Addressing Modes

The COP888CS has ten addressing modes, six for operand addressing and four for transfer of control.

OPERAND ADDRESSING MODES

Register Indirect

This is the "normal" addressing mode for the COP888CS. The operand is the data memory addressed by the B pointer or X pointer.

Register Indirect (with auto post increment or decrement of pointer)

This addressing mode is used with the LD and X instructions. The operand is the data memory addressed by the B pointer or X pointer. This is a register indirect mode that automatically post increments or decrements the B or X register after executing the instruction.

Direct

The instruction contains an 8-bit address field that directly points to the data memory for the operand.

Immediate

The instruction contains an 8-bit immediate field as the operand.

Short Immediate

This addressing mode is used with the Load B Immediate instruction. The instruction contains a 4-bit immediate field as the operand.

Indirect

This addressing mode is used with the LAID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a data operand from the program memory.

TRANSFER OF CONTROL ADDRESSING MODES

Relative

This mode is used for the JP instruction, with the instruction field being added to the program counter to get the new program location. JP has a range from -31 to +32 to allow a 1-byte relative jump (JP + 1 is implemented by a NOP instruction). There are no "pages" when using JP, since all 15 bits of PC are used.

Absolute

This mode is used with the JMP and JSR instructions, with the instruction field of 12 bits replacing the lower 12 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory segment.

Absolute Long

This mode is used with the JMPL and JSRL instructions, with the instruction field of 15 bits replacing the entire 15 bits of the program counter (PC). This allows jumping to any location in the current 4k program memory space.

Indirect

This mode is used with the JID instruction. The contents of the accumulator are used as a partial address (lower 8 bits of PC) for accessing a location in the program memory. The contents of this program memory location serve as a partial address (lower 8 bits of PC) for the jump to the next instruction.

Note: The VIS is a special case of the Indirect Transfer of Control addressing mode, where the double byte vector associated with the interrupt is transferred from adjacent addresses in the program memory into the program counter (PC) in order to jump to the associated interrupt service routine.

Instruction Set

Register and Symbol Definition

Registers	
A	8-Bit Accumulator Register
B	8-Bit Address Register
X	8-Bit Address Register
SP	8-Bit Stack Pointer Register
PC	15-Bit Program Counter Register
PU	Upper 7 Bits of PC
PL	Lower 8 Bits of PC
C	1 Bit of PSW Register for Carry
HC	1 Bit of PSW Register for Half Carry
GIE	1 Bit of PSW Register for Global Interrupt Enable
VU	Interrupt Vector Upper Byte
VL	Interrupt Vector Lower Byte

Symbols	
[B]	Memory Indirectly Addressed by B Register
[X]	Memory Indirectly Addressed by X Register
MD	Direct Addressed Memory
Mem	Direct Addressed Memory or [B]
MemI	Direct Addressed Memory or [B] or Immediate Data
Imm	8-Bit Immediate Data
Reg	Register Memory: Addresses F0 to FF (Includes B, X and SP)
Bit	Bit Number (0 to 7)
←	Loaded with
↔	Exchanged with

Instruction Set (Continued)

INSTRUCTION SET

ADD	A,Meml	ADD	$A \leftarrow A + \text{Meml}$
ADC	A,Meml	ADD with Carry	$A \leftarrow A + \text{Meml} + C, C \leftarrow \text{Carry}$
SUBC	A,Meml	Subtract with Carry	$HC \leftarrow \text{Half Carry}$ $A \leftarrow A - \text{Meml} + C, C \leftarrow \text{Carry}$ $HC \leftarrow \text{Half Carry}$
AND	A,Meml	Logical AND	$A \leftarrow A \text{ and Meml}$
ANDSZ	A,Imm	Logical AND Immed., Skip if Zero	Skip next if $(A \text{ and Imm}) = 0$
OR	A,Meml	Logical OR	$A \leftarrow A \text{ or Meml}$
XOR	A,Meml	Logical EXclusive OR	$A \leftarrow A \text{ xor Meml}$
IFEQ	MD,Imm	IF Equal	Compare MD and Imm, Do next if $MD = \text{Imm}$
IFEQ	A,Meml	IF Equal	Compare A and Meml, Do next if $A = \text{Meml}$
IFNE	A,Meml	IF Not Equal	Compare A and Meml, Do next if $A \neq \text{Meml}$
IFGT	A,Meml	IF Greater Than	Compare A and Meml, Do next if $A > \text{Meml}$
IFBNE	#	If B Not Equal	Do next if lower 4 bits of $B \neq \text{Imm}$
DRSZ	Reg	Decrement Reg., Skip if Zero	$\text{Reg} \leftarrow \text{Reg} - 1, \text{Skip if Reg} = 0$
SBIT	#,Mem	Set BIT	1 to bit, Mem (bit = 0 to 7 immediate)
RBIT	#,Mem	Reset BIT	0 to bit, Mem
IFBIT	#,Mem	IF BIT	If bit in A or Mem is true do next instruction
RPND		Reset PeNDing Flag	Reset Software Interrupt Pending Flag
X	A,Mem	EXchange A with Memory	$A \leftrightarrow \text{Mem}$
LD	A,Meml	LoaD A with Memory	$A \leftarrow \text{Meml}$
LD	B,Imm	LoaD B with Immed.	$B \leftarrow \text{Imm}$
LD	Mem,Imm	LoaD Memory Immed	$\text{Mem} \leftarrow \text{Imm}$
LD	Reg,Imm	LoaD Register Memory Immed.	$\text{Reg} \leftarrow \text{Imm}$
X	A, [B ±]	EXchange A with Memory [B]	$A \leftrightarrow [B], (B \leftarrow B \pm 1)$
X	A, [X ±]	EXchange A with Memory [X]	$A \leftrightarrow [X], (X \leftarrow X \pm 1)$
LD	A, [B ±]	LoaD A with Memory [B]	$A \leftarrow [B], (B \leftarrow B \pm 1)$
LD	A, [X ±]	LoaD A with Memory [X]	$A \leftarrow [X], (X \leftarrow X \pm 1)$
LD	[B ±],Imm	LoaD Memory [B] Immed.	$[B] \leftarrow \text{Imm}, (B \leftarrow B \pm 1)$
CLR	A	CLeaR A	$A \leftarrow 0$
INC	A	INCRement A	$A \leftarrow A + 1$
DEC	A	DECReamentA	$A \leftarrow A - 1$
LAI	A	LoaD A InDirect from ROM	$A \leftarrow \text{ROM (PU,A)}$
DCOR	A	Decimal CORrect A	$A \leftarrow \text{BCD correction of A (follows ADC, SUBC)}$
RRC	A	RotatE A Right thru C	$C \rightarrow A7 \rightarrow \dots \rightarrow A0 \rightarrow C$
RLC	A	RotatE A Left thru C	$C \leftarrow A7 \leftarrow \dots \leftarrow A0 \leftarrow C$
SWAP	A	SWAP nibbles of A	$A7 \dots A4 \leftrightarrow A3 \dots A0$
SC		Set C	$C \leftarrow 1, HC \leftarrow 1$
RC		Reset C	$C \leftarrow 0, HC \leftarrow 0$
IFC		IF C	If C is true, do next instruction
IFNC		IF Not C	If C is not true, do next instruction
POP	A	POP the stack into A	$\text{SP} \leftarrow \text{SP} + 1, A \leftarrow [\text{SP}]$
PUSH	A	PUSH A onto the stack	$[\text{SP}] \leftarrow A, \text{SP} \leftarrow \text{SP} - 1$
VIS		Vector to Interrupt Service Routine	$\text{PU} \leftarrow [\text{VU}], \text{PL} \leftarrow [\text{VL}]$
JMPL	Addr.	Jump absolute Long	$\text{PC} \leftarrow \text{ii} (\text{ii} = 15 \text{ bits}, 0 \text{ to } 32\text{k})$
JMP	Addr.	Jump absolute	$\text{PC9} \dots 0 \leftarrow \text{i} (\text{i} = 12 \text{ bits})$
JP	Disp.	Jump relative short	$\text{PC} \leftarrow \text{PC} + \text{r} (\text{r} \text{ is } -31 \text{ to } +32, \text{ except } 1)$
JSRL	Addr.	Jump SubRoutine Long	$[\text{SP}] \leftarrow \text{PL}, [\text{SP}-1] \leftarrow \text{PU}, \text{SP}-2, \text{PC} \leftarrow \text{ii}$
JSR	Addr	Jump SubRoutine	$[\text{SP}] \leftarrow \text{PL}, [\text{SP}-1] \leftarrow \text{PU}, \text{SP}-2, \text{PC9} \dots 0 \leftarrow \text{i}$
JID		Jump InDirect	$\text{PL} \leftarrow \text{ROM (PU,A)}$
RET		RETurn from subroutine	$\text{SP} + 2, \text{PL} \leftarrow [\text{SP}], \text{PU} \leftarrow [\text{SP}-1]$
RETSK		RETurn and SKip	$\text{SP} + 2, \text{PL} \leftarrow [\text{SP}], \text{PU} \leftarrow [\text{SP}-1]$
RETI		RETurn from Interrupt	$\text{SP} + 2, \text{PL} \leftarrow [\text{SP}], \text{PU} \leftarrow [\text{SP}-1], \text{GIE} \leftarrow 1$
INTR		Generate an Interrupt	$[\text{SP}] \leftarrow \text{PL}, [\text{SP}-1] \leftarrow \text{PU}, \text{SP}-2, \text{PC} \leftarrow \text{OFF}$
NOP		No OPeration	$\text{PC} \leftarrow \text{PC} + 1$

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instructions taking two bytes).

Most single byte instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

Bytes and Cycles per Instruction

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

	[B]	Direct	Immed.
ADD	1/1	3/4	2/2

Where,

i is the immediate data

Md is a directly addressed memory location

* is an unused opcode

Note: The opcode 60 Hex is also the opcode for IFBIT #i,A

Mask Options

The COP888CS mask programmable options are shown below. The options are programmed at the same time as the ROM pattern submission.

OPTION 1: CLOCK CONFIGURATION

- = 1 Crystal Oscillator (CKI/10)
 - G7 (CKO) is clock generator output to crystal/resonator
 - CKI is the clock input
- = 2 Single-pin RC controlled oscillator (CKI/10)
 - G7 is available as a HALT restart and/or general purpose input

OPTION 2: HALT

- = 1 Enable HALT mode
- = 2 Disable HALT mode

OPTION 3: OPTIONS BONDING

- = 1 44-Pin PLCC
- = 2 40-Pin DIP
- = 3 NA
- = 4 28-Pin DIP
- = 5 28-Pin SO

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bar graph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefineable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC® via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS-232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

MHW-884CG28D5PC	28 DIP	4.5V-5.5V	COP884CS
MHW-884CG28DWPC	28 DIP	2.5V-6.0V	COP884CS
MHW-888CG40D5PC	40 DIP	4.5V-5.5V	COP888CS
MHW-888CG40DWPC	40 DIP	2.5V-6.0V	COP888CS
MHW-888CG44D5PC	44 PLCC	4.5V-5.5V	COP888CS
MHW-888CG44DWPC	44 PLCC	2.5V-6.0V	COP888CS

Development Support (Continued)

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 FAX: (206) 882-1043

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM® PC/XT®, PC-AT® or compatible	424410527-001

Single Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP888CSMHXL-X	X = 1 : Crystal X = 3 : R/C	44 LDCC	Multi-Chip Module (MCM), UV Erasable	COP888CS
COP888CSMHD-X	X = 1 : Crystal X = 3 : R/C	40 DIP	MCM, UV Erasable	COP888CS

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator Board for 28 DIP Multi-Chip Module (MCM) and for use with Scrambler Boards	COP884CSMHD
COP8-SCRM-DIP	MCM Scrambler Board for 40 DIP Socket	COP888CSMHD
COP8-SCRM-PCC	MCM Scrambler Board for 44 PLCC/LDCC	COP888CSMHXL
COP8-SCRM-SBX	MCM Scrambler Board for 28 LCC Socket	COP884CSMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler Board	COP884CSMHD, COP888CSMHD
COP8-PRGM-PCC	Duplicator Board with COP8-SCRM-PCC Scrambler Board	COP888CSMEL, COP884CSMHD

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 Baud

Set-up: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs., 7 Days

COP8780C/COP8781C/COP8782C

Single-Chip EPROM/OTP Microcontrollers

General Description

The COP8780C, COP8781C and COP8782C are members of the COP8™ 8-bit microcontroller family. They are fully static microcontrollers, fabricated using double-metal, double poly silicon gate microCMOS EPROM technology. These devices are available as UV erasable or One Time Programmable (OTP). These low cost microcontrollers are complete microcomputers containing all system timing, interrupt logic, EPROM, RAM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS™ serial I/O, a 16-bit timer/counter with associated 16-bit autoreload/capture register, and a multi-sourced interrupt. Each I/O pin has software selectable options to adapt the device to the specific application. These devices operate over a voltage range of 4.5V to 6.0V. An efficient, regular instruction set operating at a 1 μs instruction cycle rate provides optimal throughput.

The COP8780C, COP8781C and COP8782C can be configured to EMULATE the COP880C, COP840C and COP820C microcontrollers.

Features

- Low cost 8-bit microcontroller
- Fully static CMOS
- 4096 x 8 on-chip UV erasable or OTP EPROM
- EPROM security
- 128 or 64 bytes of on-chip RAM, user configurable
- Crystal, RC or External Oscillator, user configurable
- 1 μs instruction time (10 MHz clock)
- Low current drain
- Extra-low current static HALT mode

- Single supply operation: 4.5V to 6.0V
- 8-bit stack pointer (stack in RAM)
- 16-bit read/write timer operates in a variety of modes
 - PWM (Pulse Width Modulation) mode with 16-bit autoreload register
 - External Event Counter mode, with selectable edge
 - Input Capture mode (selectable edge) with 16-bit capture register
- Multi-source interrupt
 - External interrupt with selectable edge
 - Timer interrupt or capture interrupt
 - Software interrupt
- Powerful instruction set, with most instructions single byte
- Many single byte, single cycle instructions
- BCD arithmetic instructions
- MICROWIRE/PLUS serial I/O
- Software selectable I/O options (TRI-STATE, push-pull, weak pull-up)
- Temperature ranges: -40°C to +85°C
- Schmitt trigger inputs on G port

COP8780C/COP8781C/COP8782C**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Programming Voltage V_{PP} (RESET pin) and ME (pin G6)	14V
Voltage at any Pin	-0.3V to $V_{CC} + 0.3V$

Total Current into V_{CC} Pin (Source)	50 mA
Total Current out of GND Pin (Sink)	60 mA
Storage Temperature Range	-65°C to +150°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

DC Electrical Characteristics COP87XXC; -40°C ≤ T_A ≤ +85°C unless otherwise specified

Parameter	Condition	Min	Typ	Max	Units
Operating Voltage		4.5		6.0	V
Power Supply Ripple (Note 1)	Peak to Peak			0.1 V_{CC}	V
Supply Current				21	mA
CKI = 10 MHz (Note 2)	$V_{CC} = 6V, t_c = 1 \mu s$			10	μA

All Others				3	mA
Maximum Input Current (Notes 4, 6) without Latchup (Room Temp)	Room Temp			±200	mA
RAM Retention Voltage, V_r (Note 5)		2.0			V
Input Capacitance	(Note 6)			7	pF
Load Capacitance on D2	(Note 6)			1000	pF

Note 1: Rate of voltage change must be less than 0.5V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the crystal configurations. Halt test conditions: All Inputs tied to V_{CC} L, C, and G port I/O's configured as outputs and programmed low; D outputs programmed low; the window for UV erasable packages is completely covered with an opaque cover to prevent light from falling onto the die during HALT mode test. Parameter refers to HALT mode entered via setting bit 7 of the G Port data register.

Note 4: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typ). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

Note 5: To maintain RAM integrity, the voltage must not be dropped or raised instantaneously.

Note 6: Parameter characterized but not tested.

FIGURE 3. COP8780C Connection Diagrams

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

RESET is the master reset input. See Reset description.

PORT I is an 8-bit Hi-Z input port.

PORT L is an 8-bit I/O port.

PORT C is a 4-bit I/O port.

Three memory locations are allocated for the L, G and C ports, one each for data register, configuration register and the input pins. Reading bits 4–7 of the C-Configuration register, data register, and input pins returns undefined data.

There are two registers associated with the L and C ports: a data register and a configuration register. Therefore, each L and C I/O bit can be individually configured under software control as shown below:

Config.	Data	Ports L and C Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

On the 20- and 28-pin parts, it is recommended that all bits of Port C be configured as outputs to minimize current.

PORT G is an 8-bit port with 6 I/O pins (G0–G5) and 2 input pins (G6, G7). All eight G-pins have Schmitt Triggers on the inputs.

There are two registers associated with the G port: a data register and a configuration register. Therefore, each G port bit can be individually configured under software control as shown below:

Config.	Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

Since G6 and G7 are input only pins, any attempt by the user to configure them as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. The device will be placed in the HALT mode by writing a one to the G7 bit in the G-port data register.

Six pins of Port G have alternate features:

G0 INTR (an external interrupt)

G3 TIO (timer/counter input/output)

G4 SO (MICROWIRE/PLUS serial data output)

G5 SK (MICROWIRE/PLUS clock I/O)

G6 SI (MICROWIRE/PLUS serial data input)

G7 CKO crystal oscillator output (selected by programming the ECON register) or HALT Restart/general purpose input

Pins G1 and G2 currently do not have any alternate functions.

PORT D is an 8-bit output port that is preset high when RESET goes low. Care must be exercised with the D2 pin operation. At RESET, the external loads on this pin must ensure that the output voltages stay above 0.7 V_{CC} to pre-

vent the chip from entering special modes. Also, keep the external loading on D2 to less than 1000 pF.

Functional Description

Figure 1 shows the block diagram of the internal architecture. Data paths are illustrated in simplified form to depict how the various logic elements communicate with each other in implementing the instruction set of the device.

ALU AND CPU REGISTERS

The ALU can do an 8-bit addition, subtraction, logical or shift operation in one cycle time.

There are five CPU registers:

A is the 8-bit Accumulator register

PU is the upper 7 bits of the program counter (PC)

PL is the lower 8 bits of the program counter (PC)

B is the 8-bit address register, can be auto incremented or decremented.

X is the 8-bit alternate address register, can be incremented or decremented.

SP is the 8-bit stack pointer, which points to the subroutine/interrupt stack in RAM. The SP must be initialized with software (usually to RAM address 06F Hex with 128 bytes of on-chip RAM selected, or to RAM address 02F Hex with 64 bytes of on-chip RAM selected). The SP is used with the subroutine call and return instructions, and with the interrupts.

B, X and SP registers are mapped into the on-chip RAM. The B and X registers are used to address the on-chip RAM. The SP register is used to address the stack in RAM during subroutine calls and returns.

PROGRAM MEMORY

The COP8780C contains 4096 bytes of UV erasable or OTP EPROM memory. This memory is mapped in the program memory address space from 0000 to 0FFF Hex. The program memory may contain either instructions or data constants, and is addressed by the 15-bit program counter (PC). The program memory can be indirectly read by the LAID (Load Accumulator Indirect) instruction for table lookup of constant data.

All locations in the EPROM program memory will contain 0FF Hex (all 1's) after the COP8780C is erased. OTP parts are shipped with all locations already erased to 0FF Hex. Unused EPROM locations should always be programmed to 00 Hex so that the software trap can be used to halt run-away program operation.

The COP8780C can be configured to inhibit external reads of the program memory. This is done by programming the security bit in the ECON (EPROM configuration) register to zero. See the ECON REGISTER section for more details.

DATA MEMORY

The data memory address space includes on-chip RAM, I/O, and registers. Data memory is addressed directly by instructions, or indirectly by means of the B, X, or SP pointers. The COP8780C can be configured to have either 64 or 128 bytes of RAM, depending on the value of the "RAM SIZE" bit in the ECON (EPROM CONFIGURATION) register. The sixteen bytes of RAM located at data memory address 0F0–0FF are designated as "registers". These sixteen registers can be decremented and tested with the DRSZ (Decrement Register and Skip if Zero) instruction.

Functional Description (Continued)

The three pointers X, B, and SP are memory mapped into this register address space at addresses 0FC, 0FE, and 0FD respectively. The remaining registers are available for general usage.

Any bit of data memory can be directly set, reset or tested. All of the I/O registers and control registers (except A and PC) are memory mapped. Consequently, any of the I/O bits or control register bits can be directly and individually set, reset, or tested.

ECON (EPROM CONFIGURATION) REGISTER

The ECON register is used to configure the user selectable clock, security, and RAM size options. The register can be programmed and read only in EPROM programming mode. Therefore, the register should be programmed at the same time as the program memory locations 0000 through 0FFF Hex. UV erasable parts are shipped with 0FF Hex in this register while the OTP parts are shipped with 07F Hex in this register. Erasing the EPROM program memory also erases the ECON register.

The COP8780C has a security feature which, when enabled, prevents reading of the EPROM program memory. The security bit in the ECON register determines whether security is enabled or disabled. If the security option is enabled, then any attempt to externally read the contents of the EPROM will result in the value E0 Hex being read from all program memory locations. If the security option is disabled, the contents of the internal EPROM may be read. The ECON register is readable regardless of the state of the security bit.

The format of the COP8780C ECON register is as follows:

TABLE I

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0	X	SECURITY	CKI 2	CKI 1	X	RAM SIZE	X

Bit 7 = 0 Must be programmed to zero.

Bit 6 = X Don't care.

Bit 5 = 1 Security disabled. EPROM read and write are allowed.

= 0 Security enabled. EPROM read and write are not allowed.

Bits 4,3

= 1,1 External CKI option selected.

= 0,1 Not allowed.

= 1,0 RC oscillator option selected.

= 0,0 Crystal oscillator option selected.

Bit 2 = X Don't care.

Bit 1 = 1 Selects 128 byte RAM option. This emulates COP840 and COP880.

= 0 Selects 64 byte RAM option. This emulates COP820.

Bit 0 = X Don't care.

RESET

The $\overline{\text{RESET}}$ input when pulled low initializes the microcontroller. Initialization will occur whenever the $\overline{\text{RESET}}$ input is pulled low. Upon initialization, the Ports L, G and C are placed in the TRI-STATE mode and the Port D is set high. The PC, PSW and CNTRL registers are cleared. The data and configuration registers for Ports L, G and C are cleared.

The external RC network shown in *Figure 4* should be used to ensure that the $\overline{\text{RESET}}$ pin is held low until the power supply to the chip stabilizes.

TL/DD/11299-7

RC \geq 5X Power Supply Rise Time

FIGURE 4. Recommended Reset Circuit

OSCILLATOR CIRCUITS

Figure 5 shows the three clock oscillator configurations available for the device. The CKI 1 and CKI 2 bits in the ECON register are used to select the clock option. See the ECON REGISTER section for more details.

A. Crystal Oscillator

The device can be driven by a crystal clock. The crystal network is connected between the pins CKI and CKO.

Table II shows the component values required for various standard crystal frequencies.

B. External Oscillator

CKI can be driven by an external clock signal provided it meets the specified duty cycle, rise and fall times, and input levels. In External oscillator mode, G7 is available as a general purpose input and/or HALT restart control.

C. R/C Oscillator

CKI can be configured as a single pin RC controlled oscillator. In RC oscillator mode, G7 is available as a general purpose input and/or HALT restart control.

Table III shows the variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/11299-8

FIGURE 5. Crystal, External and R-C Connection Diagrams

Functional Description (Continued)

TABLE II. Crystal Oscillator Configuration, $T_A = 25^\circ\text{C}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)	Conditions
0	1	30	30–36	10	$V_{CC} = 5\text{V}$
0	1	30	30–36	4	$V_{CC} = 5\text{V}$

TABLE III. RC Oscillator Configuration, $T_A = 25^\circ\text{C}$

R (k Ω)	C (pF)	CKI Freq. (MHz)	Instr. Cycle (μs)	Conditions
3.3	82	2.2 to 2.7	3.7 to 4.6	$V_{CC} = 5\text{V}$
5.6	100	1.1 to 1.3	7.4 to 9.0	$V_{CC} = 5\text{V}$
6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5\text{V}$

Note: (R/C Oscillator Configuration): $3\text{k} \leq R \leq 200\text{k}$, $50\text{ pF} \leq C \leq 200\text{ pF}$.

HALT MODE

The device supports a power saving mode of operation: HALT. The controller is placed in the HALT mode by setting the G7 data bit, alternatively the user can stop the clock input. (Stopping the clock input will draw more current than setting the G7 data bit.) In the HALT mode all internal processor activities including the clock oscillator are stopped. The fully static architecture freezes the state of the controller and retains all information until continuing. In the HALT mode, power requirements are minimal as it draws only leakage currents and output current. The applied voltage (V_{CC}) may be decreased down to V_r (minimum RAM retention voltage) without altering the state of the machine.

There are two ways to exit the HALT mode: via the RESET or by the G7 pin. A low on the RESET line reinitializes the microcontroller and starts execution from address 0000H. In external and RC oscillator modes, a low to high transition on the G7 pin also causes the microcontroller to come out of the HALT mode. Execution resumes at the address following the HALT instruction. Except for the G7 data bit, which gets reset, all RAM locations retain the values they had prior to execution of the "HALT" instruction. It is required that the first instruction following the "HALT" instruction be a "NOP" in order to synchronize the clock.

INTERRUPTS

The device has a sophisticated interrupt structure to allow easy interface to the real world. There are three possible interrupt sources, as shown below.

A maskable interrupt on external G0 input (positive or negative edge sensitive under software control)

A maskable interrupt on timer underflow or timer capture

A non-maskable software/error interrupt on opcode zero

INTERRUPT CONTROL

The GIE (global interrupt enable) bit enables the interrupt function. This is used in conjunction with ENI and ENTI to

select one or both of the interrupt sources. This bit is reset when interrupt is acknowledged.

ENI and ENTI bits select external and timer interrupts respectively. Thus the user can select either or both sources to interrupt the microcontroller when GIE is enabled.

IEDG selects the external interrupt edge (0 = rising edge, 1 = falling edge). The user can get an interrupt on both rising and falling edges by toggling the state of IEDG bit after each interrupt.

IPND and TPNB bits signal which interrupt is pending. After an interrupt is acknowledged, the user can check these two bits to determine which interrupt is pending. This permits the interrupts to be prioritized under software. The pending flags have to be cleared by the user. Setting the GIE bit high inside the interrupt subroutine allows nested interrupts.

The software interrupt does not reset the GIE bit. This means that the controller can be interrupted by other interrupt sources while servicing the software interrupt.

INTERRUPT PROCESSING

The interrupt, once acknowledged, pushes the program counter (PC) onto the stack and the stack pointer (SP) is decremented twice. The Global Interrupt Enable (GIE) bit is reset to disable further interrupts. The microcontroller then vectors to the address 00FFH and resumes execution from that address. This process takes 7 cycles to complete. At the end of the interrupt subroutine, any of the following three instructions return the processor back to the main program: RET, RETSK or RETI. Either one of the three instructions will pop the stack into the program counter (PC). The stack pointer is then incremented twice. The RETI instruction additionally sets the GIE bit to re-enable further interrupts.

Any of the three instructions can be used to return from a hardware interrupt subroutine. The RETSK instruction should be used when returning from a software interrupt subroutine to avoid entering an infinite loop.

Functional Description (Continued)

FIGURE 6. Interrupt Block Diagram

TL/DD/11299-9

DETECTION OF ILLEGAL CONDITIONS

The device incorporates a hardware mechanism that allows it to detect illegal conditions which may occur from coding errors, noise and "brown out" voltage drop situations. Specifically, it detects cases of executing out of undefined EPROM area and unbalanced stack situations.

Reading an undefined EPROM location returns 00 (hexadecimal) as its contents. The opcode for a software interrupt is also "00". Thus a program accessing undefined EPROM will cause a software interrupt.

Reading an undefined RAM location returns an FF (hexadecimal). The subroutine stack on the device grows down for each subroutine call. By initializing the stack pointer to the top of RAM, the first unbalanced return instruction will cause the stack pointer to address undefined RAM. As a result the program will attempt to execute from FFFF (hexadecimal), which is an undefined EPROM location and will trigger a software interrupt.

MICROWIRE/PLUS

MICROWIRE/PLUS is a serial synchronous bidirectional communications interface. The MICROWIRE/PLUS capability enables the device to interface with any of National Semiconductor's MICROWIRE peripherals (i.e. A/D converters, display drivers, EEPROMS, etc.) and with other microcontrollers which support the MICROWIRE/PLUS interface. It consists of an 8-bit serial shift register (SIO) with serial data input (SI), serial data output (SO) and serial shift clock (SK). Figure 7 shows the block diagram of the MICROWIRE/PLUS interface.

TL/DD/11299-10

FIGURE 7. MICROWIRE/PLUS Block Diagram

The shift clock can be selected from either an internal source or an external source. Operating the MICROWIRE/PLUS interface with the internal clock source is called the Master mode of operation. Operating the MICROWIRE/PLUS interface with an external shift clock is called the Slave mode of operation.

The CNTRL register is used to configure and control the MICROWIRE/PLUS mode. To use the MICROWIRE/PLUS, the MSEL bit in the CNTRL register is set to one. The SK clock rate is selected by the two bits, S0 and S1, in the CNTRL register. Table IV details the different clock rates that may be selected.

TABLE IV

S1	S0	SK Cycle Time
0	0	2t _c
0	1	4t _c
1	x	8t _c

where,

t_c is the instruction cycle time.

MICROWIRE/PLUS OPERATION

Setting the BUSY bit in the PSW register causes the MICROWIRE/PLUS arrangement to start shifting the data. It gets reset when eight data bits have been shifted. The user may reset the BUSY bit by software to allow less than 8 bits to shift. The device may enter the MICROWIRE/PLUS mode either as a Master or as a Slave. Figure 8 shows how two device microcontrollers and several peripherals may be interconnected using the MICROWIRE/PLUS arrangement.

Master MICROWIRE/PLUS Operation

In the MICROWIRE/PLUS Master mode of operation the shift clock (SK) is generated internally by the device. The MICROWIRE/PLUS Master always initiates all data exchanges (Figure 8). The MSEL bit in the CNTRL register must be set to enable the SO and SK functions on the G Port. The SO and SK pins must also be selected as outputs by setting appropriate bits in the Port G configuration register. Table V summarizes the bit settings required for Master mode of operation.

SLAVE MICROWIRE/PLUS OPERATION

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL

Functional Description (Continued)

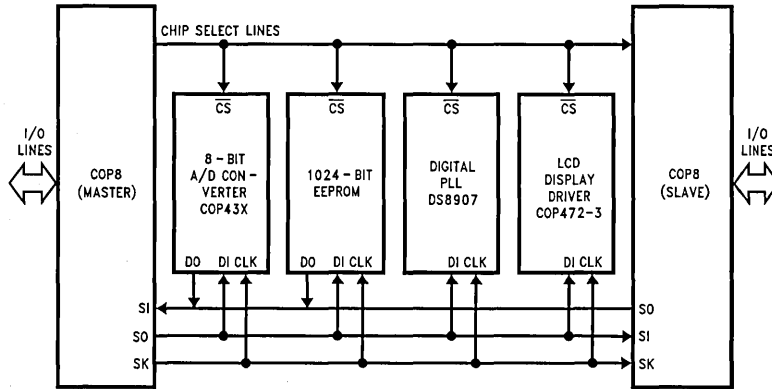

FIGURE 8. MICROWIRE/PLUS Application

TL/DD/11299-11

bit in the CNTRL register enables the SO and SK functions on the G Port. The SK pin must be selected as an input and the SO pin selected as an output pin by appropriately setting up the Port G configuration register. Table V summarizes the settings required to enter the Slave mode of operation. The user must set the BUSY flag immediately upon entering the Slave mode. This will ensure that all data bits sent by the Master will be shifted properly. After eight clock pulses the BUSY flag will be cleared and the sequence may be repeated (Figure 8).

TABLE V

G4 Config. Bit	G5 Config. Bit	G4 Fun.	G5 Fun.	G6 Fun.	Operation
1	1	SO	Int. SK	SI	MICROWIRE Master
0	1	TRI-STATE	Int. SK	SI	MICROWIRE Master
1	0	SO	Ext. SK	SI	MICROWIRE Slave
0	0	TRI-STATE	Ext. SK	SI	MICROWIRE Slave

TIMER/COUNTER

The device has a powerful 16-bit timer with an associated 16-bit register enabling it to perform extensive timer functions. The timer T1 and its register R1 are each organized as two 8-bit read/write registers. Control bits in the register CNTRL allow the timer to be started and stopped under software control. The timer-register pair can be operated in one of three possible modes. Table VI details various timer operating modes and their requisite control settings.

MODE 1. TIMER WITH AUTO-LOAD REGISTER

In this mode of operation, the timer T1 counts down at the instruction cycle rate. Upon underflow the value in the register R1 gets automatically reloaded into the timer which continues to count down. The timer underflow can be programmed to interrupt the microcontroller. A bit in the control register CNTRL enables the TIO (G3) pin to toggle upon timer underflows. This allows the generation of square-wave outputs or pulse width modulated outputs under software control (Figure 9).

MODE 2. EXTERNAL COUNTER

In this mode, the timer T1 becomes a 16-bit external event counter. The counter counts down upon an edge on the TIO pin. Control bits in the register CNTRL program the counter to decrement either on a positive edge or on a negative edge. Upon underflow the contents of the register R1 are automatically copied into the counter. The underflow can also be programmed to generate an interrupt (Figure 9).

MODE 3. TIMER WITH CAPTURE REGISTER

Timer T1 can be used to precisely measure external frequencies or events in this mode of operation. The timer T1 counts down at the instruction cycle rate. Upon the occurrence of a specified edge on the TIO pin the contents of the timer T1 are copied into the register R1. Bits in the control register CNTRL allow the trigger edge to be specified either as a positive edge or as a negative edge. In this mode the user can elect to be interrupted on the specified trigger edge (Figure 10).

TABLE VI. Timer Operating Modes

CNTRL Bits 7 6 5	Operation Mode	T Interrupt	Timer Counts On
0 0 0	External Counter w/Auto-Load Reg.	Timer Underflow	TIO Pos. Edge
0 0 1	External Counter w/Auto-Load Reg.	Timer Underflow	TIO Neg. Edge
0 1 0	Not Allowed	Not Allowed	Not Allowed
0 1 1	Not Allowed	Not Allowed	Not Allowed
1 0 0	Timer w/Auto-Load Reg.	Timer Underflow	t _c
1 0 1	Timer w/Auto-Load Reg./Toggle TIO Out	Timer Underflow	t _c
1 1 0	Timer w/Capture Register	TIO Pos. Edge	t _c
1 1 1	Timer w/Capture Register	TIO Neg. Edge	t _c

Functional Description (Continued)

FIGURE 9. Timer/Counter Auto Reload Mode Block Diagram

FIGURE 10. Timer Capture Mode Block Diagram

TIMER PWM APPLICATION

Figure 11 shows how a minimal component D/A converter can be built out of the Timer-Register pair in the Auto-Reload mode. The timer is placed in the "Timer with auto reload" mode and the TIO pin is selected as the timer output. At the outset the TIO pin is set high, the timer T1 holds the on time and the register R1 holds the signal off time. Setting TRUN bit starts the timer which counts down at the instruction cycle rate. The underflow toggles the TIO output and copies the off time into the timer, which continues to run. By alternately loading in the on time and the off time at each successive interrupt a PWM frequency can be easily generated.

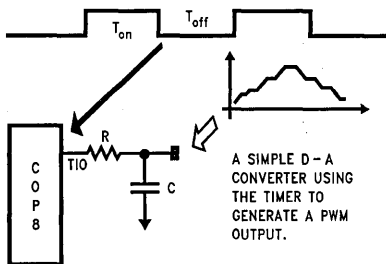

FIGURE 11. Timer Application

Control Registers

CNTRL REGISTER (ADDRESS X'00EE)

The Timer and MICROWIRE/PLUS control register contains the following bits:

- S1 & S0 Select the MICROWIRE/PLUS clock divide-by
- IEDG External interrupt edge polarity select (0 = rising edge, 1 = falling edge)
- MSEL Enable MICROWIRE/PLUS functions SO and SK
- TRUN Start/Stop the Timer/Counter (1 = run, 0 = stop)
- TC3 Timer input edge polarity select (0 = rising edge, 1 = falling edge)
- TC2 Selects the capture mode
- TC1 Selects the timer mode

TC1	TC2	TC3	TRUN	MSEL	IEDG	S1	S0	
Bit 7							Bit 0	

PSW REGISTER (ADDRESS X'00EF)

The PSW register contains the following select bits:

- GIE Global interrupt enable
- ENI External interrupt enable
- BUSY MICROWIRE/PLUS busy shifting
- IPND External interrupt pending
- ENTI Timer interrupt enable
- TPND Timer interrupt pending
- C Carry Flag
- HC Half carry Flag

Addressing Modes

REGISTER INDIRECT

This is the "normal" mode of addressing for the device. The operand is the memory location addressed by the B register or X register.

DIRECT

The instruction contains an 8-bit address field that directly points to the data memory location for the operand.

IMMEDIATE

The instruction contains an 8-bit immediate field as the operand.

REGISTER INDIRECT (AUTO INCREMENT AND DECREMENT)

This is a register indirect mode that automatically increments or decrements the B or X register after executing the instruction.

RELATIVE

This mode is used for the JP instruction, the instruction field is added to the program counter to get the new program location. JP has a range of -31 to +32 to allow a one byte relative jump (JP + 1 is implemented by a NOP instruction). There are no "pages" when using JP, all 15 bits of PC are used.

Memory Map

All RAM, ports and registers (except A and PC) are mapped into data memory address space.

RAM Select	Address	Contents
64 On-Chip RAM Bytes Selected by ECON reg.	00–2F 30–7F	48 On-Chip RAM Bytes Unused RAM Address Space (Reads as all 1's)
128 On-Chip RAM Bytes Selected by ECON reg.	00–6F 70–7F	112 On-chip RAM Bytes Unused RAM Address Space (Reads as all 1's)
	80 to BF	Expansion Space for On-Chip EERAM
	C0 to CF	Expansion Space for I/O and Registers
	D0 to DF	On-Chip I/O and Registers
	D0	Port L Data Register
	D1	Port L Configuration Register
	D2	Port L Input Pins (Read Only)
	D3	Reserved for Port L
	D4	Port G Data Register
	D5	Port G Configuration Register
	D6	Port G Input Pins (Read Only)
	D7	Port I Input Pins (Read Only)
	D8	Port C Data Register
	D9	Port C Configuration Register
	DA	Port C Input Pins (Read Only)
	DB	Reserved for Port C
	DC	Port D Data Register
	DD–DF	Reserved for Port D
	E0 to EF	On-Chip Functions and Registers
	E0–E7	Reserved for Future Parts
	E8	Reserved
	E9	MICROWIRE/PLUS Shift Register
	EA	Timer Lower Byte
	EB	Timer Upper Byte
	EC	Timer Autoload Register Lower Byte
	ED	Timer Autoload Register Upper Byte
	EE	CNTRL Control Register
	EF	PSW Register
	F0 to FF	On-Chip RAM Mapped as Registers
	FC	X Register
	FD	SP Register
	FE	B Register

Reading unused memory locations below 7FH will return all ones. Reading other unused memory locations will return undefined data.

Instruction Set

REGISTER AND SYMBOL DEFINITIONS

Registers

A	8-bit Accumulator register
B	8-bit Address register
X	8-bit Address register
SP	8-bit Stack pointer register
PC	15-bit Program counter register
PU	upper 7 bits of PC
PL	lower 8 bits of PC
C	1-bit of PSW register for carry
HC	Half Carry
GIE	1-bit of PSW register for global interrupt enable

Symbols

[B]	Memory indirectly addressed by B register
[X]	Memory indirectly addressed by X register
Mem	Direct address memory or [B]
Meml	Direct address memory or [B] or Immediate data
Imm	8-bit Immediate data
Reg	Register memory: addresses F0 to FF (Includes B, X and SP)
Bit	Bit number (0 to 7)
←	Loaded with
↔	Exchanged with

where, i is the immediate data Md is a directly addressed memory location * is an unused opcode (see following table)

Instruction Execution Time

Most instructions are single byte (with immediate addressing mode instruction taking two bytes).

Most single instructions take one cycle time to execute.

See the BYTES and CYCLES per INSTRUCTION table for details.

BYTES and CYCLES per INSTRUCTION

The following table shows the number of bytes and cycles for each instruction in the format of byte/cycle.

Arithmetic Instructions (Bytes/Cycles)

	[B]	Direct	Immed.
ADD	1/1	3/4	2/2
ADC	1/1	3/4	2/2
SUBC	1/1	3/4	2/2

99	NOP	B9	NOP
9F	LD [B], #i	BF	LD A, [X]
A7	X A, [B]		
A8	NOP		

Programming the COP8780C

Programming of the COP87XXC single-chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 FAX: (206) 882-1043

The National Semiconductor Duplicator Board is a stand alone programmer capable of supporting all COP8780C package types when combined with available adaptor boards (Scrambler Boards). The duplicator works in conjunction with a pre-programmed source EPROM containing the application program. (The source EPROM may be programmed via a standard programmer.) The duplicator board essentially copies the information from the source EPROM into the COP8780C program memory.

In addition to the application program stored in locations 0000 through 0FFF Hex, the source EPROM must contain a value for the ECON register at location 1FFF Hex. The following tables provide examples of some ECON register values. For more detailed information refer to the ECON REGISTER section.

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-87A	Duplicator Board with COP87XX Scrambler for 28 DIP, 28 SO, and 40 DIP	COP8781CN, COP8781CJ, COP8781CWM, COP8781CMC, COP8780CN, COP8780CJ
COP8-PRGM-87B	Duplicator Board with COP87XX Scrambler for 20 DIP, 20 SO, and 44 PLCC/LDCC	COP8780CV, COP8780CEL, COP8782CN, COP8782CWM, COP8782C5, COP8782CMC

EPROM Security Enabled

RAM Memory	External CKI	RC Oscillator	Crystal Oscillator
64 Bytes	18	10	00
128 Bytes	1A	12	02

EPROM Security Disabled

RAM Memory	External CKI	RC Oscillator	Crystal Oscillator
64 Bytes	38	30	20
128 Bytes	3A	32	22

ERASING THE COP8780C EPROM

The COP8780C EPROM program memory is erased by exposing the transparent window on the UV erasable packages to an ultraviolet light source. Erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (Å). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å to 4000Å range.

After programming, opaque labels should be placed over the window of the device to prevent functional failure due to the generation of photo currents, erasure and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the COP8780C is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The integrated dose (UV intensity × exposure time) for erasure should be a minimum of 30W-sec/cm².

The COP8780C device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities.

Programming the COP8780C (Continued)

Minimum COP8780C Erasure Time

Light Intensity (Micro-Watts/cm ²)	Erasure Time* (Minutes)
15,000	36
10,000	50
8,500	60

*Does not include light intensity ramp up time.

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

Common symptoms of insufficient erasure are:

- Inability to be programmed.
- Operational malfunctions associated with V_{CC}, temperature, or clock frequency.
- Loss of data in program memory.
- A change in configuration values in the ECON register.

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kbytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges, or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes, and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bar graph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy-to-use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2 kBaud serial link keeps typical program download to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS 232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulator

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications Group. The Dial-A-Helper is an Electronic Bulletin Board information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down-loaded to disk for later use.

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user has questions, he can leave messages on our electronic bulletin board.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 baud

Setup: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs. 7 Days

COP842CMH Microcontroller Emulator

General Description

The COP842CMH hybrid emulator is a member of the COPSTM microcontroller family. The device is a two chip system in a dual cavity 20-pin DIP package. Within the package is the COP842C and a UV-erasable 8k EPROM with port recreation logic. Code executes out of the EPROM. The part contains a transparent window which allows the EPROM to be erased and re-programmed. The COP842CMH is a fully static part, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUSTM serial I/O, and a 16-bit timer/counter supporting three modes (PWM generation, External Event counter, and Input Capture). Each I/O pin has software selectable configurations. The COP842CMH operates over a voltage range of 4.5V to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

The COP842CMH is primarily intended as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only.

Features

- Form fit and function emulation device for the COP842C/COP822C
- Fully static CMOS
- 1 μ s instruction time (10 MHz clock)
- 8191 bytes EPROM/128 bytes RAM
- 16-bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - External interrupt with selectable edge
 - Timer/capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set, most instructions are single byte
- BCD arithmetic instructions
- MICROWIRE/PLUS serial I/O
- 20-pin package
- 16 input/output pins
- Software selectable I/O options (TRI-STATE®, push-pull, weak pull-up)
- Schmitt trigger inputs on Port G
- Real time emulation and full program debug offered by National's Development Systems

Ordering Information

Hybrid Emulator	Package Type	Part Emulated

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Reset (V_{PP}) and G6 (ME)	-0.3V to 14V
Voltage at any other Pin	-0.3V to $V_{CC} + 0.3V$
Total Current into V_{CC} Pin (Source)	50 mA

Total Current Out of GND Pin (Sink)	60 mA
Storage Temperature Range	-65°C to +140°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

The following AC and DC Electrical Characteristics are not tested but are for reference only.

DC Electrical Characteristics -0°C < T_A < +70°C unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units
Operating Voltage		4.5		6.0	V
Power Supply Ripple (Note 1)	Peak to Peak			0.1 V_{CC}	V
Supply Current				19	mA

Input Capacitance				7	pF

Note 1: Rate of voltage change must be less than 0.5V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. HALT test conditions: L and G ports are at TRI-STATE and tied to ground, EPROM window covered.

Note 4: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

AC Electrical Characteristics $-0^{\circ}\text{C} < T_A < +70^{\circ}\text{C}$ unless otherwise specified

FIGURE 1. MICROWIRE Timing Diagram

Pin Descriptions

ON CHIP I/O

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO).

RESET is the master reset input.

Port L is an 8-bit I/O port.

There are two registers associated with the L port: a data register and a configuration register. Therefore, each L I/O bit can be individually configured under software control as shown in the following table:

Configure	Data	Port L Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

Three RAM data memory locations are allocated for the L port, one for the data register, one for the configuration register and one for the input pins.

Port G is an 8-bit port with 6 I/O pins (G0–G5) and 2 input pins (G6, G7). All eight G-pins have Schmitt Triggers on the inputs.

There are two registers associated with the G port: a data register and a configuration register. Therefore, each G port bit can be individually configured under software control as shown below:

Configure	Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

Three RAM data memory locations are allocated for the G port, one for the data register, one for the configuration register, and one for the input pins.

Since G6 and G7 are input only pins, any attempt by the user to configure them as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. Note that the COP842CMH will be placed in the HALT mode by setting the G7 data bit.

Six Port G pins have alternate functions:

- G0 INT (External Interrupt)
- G3 TIO (Timer/Counter I/O)
- G4 SO (MICROWIRE Serial Data Output)

G5 SK (MICROWIRE Serial Clock)

G6 SI (MICROWIRE Serial Data Input)

G7 CKO Crystal Oscillator Output (Selected by Mask Option) or HALT Restart Input (General Purpose Input)

Oscillator Circuits

A. CRYSTAL OSCILLATOR—COP842CMHD-1

By selecting CKO as a clock output, CKI and CKO can be connected to make a crystal controlled oscillator. See Table II for value of R & C.

B. EXTERNAL OSCILLATOR—COP842CMHD-2

CKI can be driven by an external clock signal provided it meets the specified duty cycle, rise and fall times, and input levels. CKO (G7) is available as a general purpose input and/or Halt Control.

C. R/C OSCILLATOR—COP842CMHD-3

CKI is configured as a single pin R/C controlled Schmitt trigger oscillator. CKO (G7) is available as a general purpose input and/or HALT restart control.

Table III shows the variation in the oscillator frequencies as functions of the component (R and C) values.

FIGURE 6. Crystal, External, and R-C Oscillator Diagrams
TL/DD/10717-6

TABLE II. Crystal Oscillator Configuration, $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq. (MHz)
0	1	30	30-36	10
0	1	30	30-36	4
0	1	200	100-150	0.455

TABLE III. RC Oscillator Configuration, $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R (k Ω)	C (pF)	CKI Freq. (MHz)	Instr. Cycle (μs)
3.3	82	2.8 to 2.2	3.6 to 4.5
5.6	100	1.5 to 1.1	6.7 to 9
6.8	100	1.1 to 0.8	9 to 12.5

Programming the COP842CMH

Programming the COP842CMH hybrid emulators is accomplished through the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the value 0E7 Hex. The device will not function properly if any other value resides in this last byte's location.

The following product codes are used by the customer to order the duplicator board.

NSID	Description	Documentation
COP8-RRGM-DIP	Duplicator Board for 20-Pin DIP	User Instruction Manual

The device will also program on a Data I/O Programmer. The following table provides the programming information on a Data I/O Programmer.

COPs Part Number	Package Type	Family Code	Pin	Software Rev	Adapter
COP842CMHD	20 DIP	16F	174	V3.2	SITE48

ERASING THE COP842CMH

Erasure of program memory is achieved by removing the COP842CMH from its socket and exposing the transparent window to an ultra-violet light source.

The erasure characteristics of the COP842CMH are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000Å (Angstroms). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å–4000Å range.

After programming, opaque labels should be placed over the COP842CMH's window to prevent temporary functional failure due to the generation of photo currents or high HALT mode current.

The recommended erasure procedure for the COP842CMH is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The integrated dose (i.e., UV intensity X exposure time) for erasure should be a minimum of 30W-sec/cm².

The COP842CMH should be placed within 1 inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. Table IV shows the minimum COP842CMH erasure time for various light intensities.

An erasure system should be calibrated periodically. The distance from lamp to unit should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that full erasure is occurring.

TABLE IV. Minimum COP842CMH Erasure Time

Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)
15,000	40
10,000	50
5,000	100

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system and additionally, provides the capability of remotely accessing the development system at a customer site.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be downloaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user is having difficulty in operating the development system, he can leave messages on our electronic bulletin board, which we will respond to, or under extraordinary circumstances he can arrange for us to actually take control of his system via modem for debugging purposes.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 Baud

Set-up: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs., 7 Days

COP880CMH/COP881CMH Microcontroller Emulators

General Description

The COP880CMH/COP881CMH hybrid emulators are members of the COP^{STM} microcontroller family. The device is a two chip system in a dual cavity package. Within the package is the COP880C and a UV-erasable 8k EPROM with port recreation logic code executes of the EPROM. The devices (offered in 44-pin LDCC, 40-pin DIP and 28-pin DIP packages) contain transparent windows which allow the EPROM to be erased and re-programmed. The devices are fully static parts, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUSTM serial I/O, and a 16-bit timer/counter supporting three modes (PWM generation, External Event counter, and Input Capture). Each I/O pin has software selectable configurations. The devices operate over a voltage range of 4.5V to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

The COP881CMH (28-pin package) can be used to emulate the COP820C/COP840C.

COP880CMH and COP881CMH are intended primarily as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only.

- 1 μ s instruction time
- 8191 bytes EPROM/128 bytes RAM
- 16-bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - External interrupt with selectable edge
 - Timer/capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set; most instructions are single byte
- BCD arithmetic instructions
- MICROWIRE/PLUS serial I/O
- Packages: 44-pin LDCC with 36 I/O pins
40-pin DIP with 36 I/O pins
28-pin DIP with 24 I/O pins
- Software selectable I/O options (TRI-STATE[®], push-pull, weak pull-up)
- Schmitt trigger inputs on Port G
- Real time emulation and full program debug offered by National's Development Systems

Features

- Form fit and function emulation device for the COP880C/COP881C/COP840C/COP820C
- Fully static CMOS

Ordering Information

Hybrid Emulator	Package Type	Part Emulated

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Reset (V_{PP}) and G6 (ME)	-0.3V to 14V
Voltage at any other Pin	-0.3V to $V_{CC} + 0.3V$
Total Current into V_{CC} Pin (Source)	50 mA

Total Current Out of GND Pin (Sink) 60 mA

Storage Temperature Range -65°C to +140°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

The following AC and DC Electrical Characteristics are not tested but are for reference only.

DC Electrical Characteristics -40°C ≤ T_A ≤ +85°C unless otherwise specified

TL/DD/11022-5

FIGURE 2. MICROWIRE Timing Diagram

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an external source, an R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

RESET is the master reset input. See Reset description.

PORT I is an 8-bit Hi-Z input port.

PORT L is an 8-bit I/O port.

PORT C is a 4-bit I/O port.

Three memory locations are allocated for the L, G and C ports, one each for data register, configuration register and the input pins. Reading bits 4–7 of the C-Configuration register, data register, and input pins returns undefined data.

There are two registers associated with the L and C ports: a data register and a configuration register. Therefore, each L and C I/O bit can be individually configured under software control as shown below:

Config.	Data	Ports L and C Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

On the 28-pin part, it is recommended that all bits of Port C be configured as outputs.

PORT G is an 8-bit port with 6 I/O pins (G0–G5) and 2 input pins (G6, G7). All eight G-pins have Schmitt Triggers on the inputs.

There are two registers associated with the G port: a data register and a configuration register. Therefore, each G port bit can be individually configured under software control as shown below:

Config.	Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Pull-Up (Weak One Output)
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

Since G6 and G7 are input only pins, any attempt by the user to configure them as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. The device will be placed in the HALT mode by writing to the G7 bit in the G-port data register.

Six pins of Port G have alternate features:

G0 INTR (an external interrupt)

G3 TIO (timer/counter input/output)

G4 SO (MICROWIRE serial data output)

G5 SK (MICROWIRE clock I/O)

G6 SI (MICROWIRE serial data input)

G7 CKO crystal oscillator output (selected by mask option) or HALT restart input (general purpose input)

Pins G1 and G2 currently do not have any alternate functions.

PORT D is an 8-bit output port that is preset high when RESET goes low.

Oscillator Circuits

A. CRYSTAL OSCILLATOR

By selecting CKO as a clock output, CKI and CKO can be connected to make a crystal controlled oscillator. See Table II for value of R & C.

B. EXTERNAL OSCILLATOR

CKI can be driven by an external clock signal provided it meets the specified duty cycle, rise and fall times, and input levels. CKO (G7) is available as a general purpose input and/or Halt Control.

C. R/C OSCILLATOR

CKI is configured as a single pin R/C controlled Schmitt trigger oscillator. CKO (G7) is available as a general purpose input and/or HALT restart control.

Table III shows the variation in the oscillator frequencies as functions of the component (R and C) values.

OSCILLATOR MASK OPTIONS

The devices can be driven by crystal or external clock inputs between DC and 10 MHz. Table IV shows the clock option per package.

FIGURE 3. Crystal, External, and R/C Oscillator Diagrams

Programming the COP880CMH/COP881CMH

Programming the hybrid emulators is accomplished through the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the NSC development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the proper value specified in the following table.

TABLE V

Device	Package Type	RAM Size Emulated	Contents of Last Byte (Address 01FFF)
COP880CMH	44 LDCC 40 DIP	128	7F
COP881CMH	28 DIP	128	6F
COP881CMH	28 DIP	64	EF

COP880CMHEL	44 LDCC	16F	175	V3.2	PINSITE

ERASING THE PROGRAM MEMORY

Erasement of the EPROM program memory is achieved by removing the device from its socket and exposing the transparent window to an ultra-violet light source.

Programming the COP880CMH/COP881CMH (Continued)

The erasure characteristics of the device are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (Å). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å to 4000Å range.

After programming, opaque labels should be placed over the window of the device to prevent temporary functional failure due to the generation of photo currents, erasure, and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the devices is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The integrated dose (UV intensity \times exposure time) for erasure should be a minimum of 15 W-sec/cm².

The device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities.

Minimum Erasure Time	
Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)
15,000	20
10,000	25
5,000	50

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system and additionally, provides the capability of remotely accessing the development system at a customer site.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user is having difficulty in operating the development system, he can leave messages on our electronic bulletin board, which we will respond to, or under extraordinary circumstances he can arrange for us to actually take control of his system via modem for debugging purposes.

COP8640CMH/COP8642CMH Microcontroller Emulator

General Description

The COP8640CMH/COP8642CMH hybrid emulators are members of the COPST[™] microcontroller family. The devices (offered in 28-pin DIP LCC and 20-pin DIP) contain transparent windows which allow the EPROM to be erased and reprogrammed. They are fully static parts, fabricated using double-metal silicon gate microCMOS technology. These microcontrollers are complete microcomputers containing all system timing, interrupt logic, EPROM, RAM, EEPROM, and I/O necessary to implement dedicated control functions in a variety of applications. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUST[™] serial I/O, a 16-bit timer/counter with capture register and a multi-sourced interrupt. Each I/O pin has software selectable options to adapt the COP8640CMH/COP8642CMH to the specific application. The part operates over a voltage range of 4.5V to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a 1 microsecond per instruction rate.

COP8640CMH and COP8642CMH are intended primarily as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only.

Features

- Form fit and function emulation devices for COP8640C/COP8642C/COP8620C/COP8622C
- Fully static CMOS
- 1 μ s instruction time
- Single supply operation: 4.5V to 6.0V
- 8k bytes EPROM/64 bytes RAM/64 bytes EEPROM
- 16-Bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - Reset master clear
 - External interrupt with selectable edge
 - Timer interrupt or capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set, most instructions single byte
- BCD arithmetic instructions
- MICROWIRE/PLUS serial I/O
- 28-pin and 20-pin DIP packages
- 24 input/output pins (28-pin package)
- Software selectable I/O options (TRI-STATE[®], push-pull, weak pull-up)
- Schmitt trigger inputs on Port G
- Fully supported by National's Development Systems

Ordering Information

Hybrid Emulator	Package Type	Part Emulated

COP8640CMH/COP8642CMH (Continued)**DC Electrical Characteristics** $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$ unless otherwise specified (Continued)

Parameter	Condition	Min	Typ	Max	Units
EEPROM Characteristics					
EEPROM Write Cycle Time				10	ms
EEPROM Number of Write Cycles				10,000	Cycle
EEPROM Data Retention				10	Years

Note 1: Rate of voltage change must be less than 0.5V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L and G ports at TRI-STATE and tied to ground, all outputs low and tied to ground.

Note 4: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

AC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$ unless otherwise specified

Parameter	Condition	Min	Typ	Max	Units

Note 4: Parameter sampled but not 100% tested.

Timing Diagram

FIGURE 2. MICROWIRE/PLUS Timing

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

\overline{RESET} is the master reset input. See Reset description.

PORT I is a four bit Hi-Z input port.

PORT L is an 8-bit I/O port.

There are two registers associated with each L I/O port: a data register and a configuration register. Therefore, each L I/O bit can be individually configured under software control as shown below:

Port L Config.	Port L Data	Port L Setup
0	0	Hi-Z Inupt (TRI-STATE)
0	1	Input with Weak Pull-Up
1	0	Push-Pull "0" Output
1	1	Push-Pull "1" Output

Three data memory address locations are allocated for these ports, one for data register, one for configuration register and one for the input pins.

PORT G is an 8-bit port with 6 I/O pins (G0–G5) and 2 input pins (G6, G7). All eight G-pins have Schmitt Triggers on the inputs. The G7 pin functions as an input pin under normal operation and as the continue pin to exit the HALT mode. There are two registers with each I/O port: a data register and a configuration register. Therefore, each I/O bit can be individually configured under software control as shown below:

Port G Config.	Port G Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input with Weak Pull-Up
1	0	Push-Pull "0" Output
1	1	Push-Pull "1" Output

Three data memory address locations are allocated for these ports, one for data register, one for configuration register and one for the input pins. Since G6 and G7 are input only pins, any attempt by the user to set them up as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. Note that the chip will be placed in the HALT mode by setting the G7 data bit.

Six bits of Port G have alternate features:

G0 INTR (an external interrupt)

G3 TIO (timer/counter input/output)

G4 SO (MICROWIRE serial data output)

G5 SK (MICROWIRE clock I/O)

G6 SI (MICROWIRE serial data input)

G7 CKO crystal oscillator output (selected by mask option) or HALT restart input (general purpose input)

Pins G1 and G2 currently do not have any alternate functions.

PORT D is a four bit output port that is set high when \overline{RESET} goes low.

Functional Description

OSCILLATOR CIRCUITS

Figure 3 shows the three clock oscillator configurations. Table III shows the clock options per package.

A. CRYSTAL OSCILLATOR

The COP8640CMH/COP8642CMH can be driven by a crystal clock. The crystal network is connected between the pins CKI and CKO.

Table I shows the component values required for various standard crystal values.

B. EXTERNAL OSCILLATOR

CKI can be driven by an external clock signal. CKI is available as a general purpose input and/or HALT restart control.

C. R/C OSCILLATOR

CKI is configured as a single pin RC controlled Schmitt trigger oscillator. CKO is available as a general purpose input and/or HALT restart control.

Table II shows the variation in the oscillator frequencies (due to the part) as functions of the R/C component values (R/C tolerances not included).

TABLE I. Crystal Oscillator Configuration
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5.0\text{V}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)
0	1	30	30–36	10
0	1	30	30–36	4
5.5	1	100	100	0.455

TABLE II. RC Oscillator Configuration
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5.0\text{V}$

R (k Ω)	C (pF)	CKI Freq. (MHz)	Instr. Cycle (μs)
3.3	82	2.2 to 2.7	3.7 to 4.6
5.6	100	1.1 to 1.3	7.4 to 9.0
6.8	100	0.9 to 1.1	8.8 to 10.8

Note: $3\text{k} \leq R \leq 200\text{k}$

$50\text{ pF} \leq C \leq 200\text{ pF}$

Programming the COP8640CMH/COP8642CMH

Programming the hybrid emulators is accomplished through the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the NSC development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the proper value specified in the following table:

TABLE IV

Device	Package Type	Contents of Last Byte (Address 01FFF)
COP8640CMHD	28 DIP	6F
COP8642CMHD	20 DIP	E7

ERASING THE PROGRAM MEMORY

Erasure of the EPROM program memory is achieved by removing the device from its socket and exposing the transparent window to an ultra-violet light source.

The erasure characteristics of the device are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (Å). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å to 4000Å range.

After programming, opaque labels should be placed over the window of the device to prevent temporary functional failure due to the generation of photo currents, erasure, and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the devices is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The integrated dose (UV intensity × exposure time) for erasure should be a minimum of 15 W-sec/cm².

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

The device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities:

TABLE V. Minimum Erasure Time

Package Type	Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)
28 DIP	15,000	20
	10,000	25
	5,000	50
20 DIP	15,000	40
	10,000	50
	5,000	100

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kbytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bar graph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefineable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC® via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS 232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

MHW-8640CG28D5PC	28 DIP	4.5V-5.5V	COP8640C, 8620C
MHW-8640CG28DWPC	28 DIP	2.5V-6.0V	COP8640C, 8620C

Development Support (Continued)

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

SIMULATOR

The COP8 Designers' Toolkit is available for evaluating National Semiconductor's COP8 microcontroller family. The kit contains programmer's manuals, device datasheets, pocket reference guides, assembler and simulator which allow the user to write, test, debug and run code on an industry standard compatible PC. The simulator has a windowed user interface and can handle script files that simulate hardware inputs, interrupts and automatic command processing. The capture file feature enables the user to record to a file current cycle count and output port changes which are caused by the program under test.

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user has questions, he can leave messages on our electronic bulletin board, which we will respond to.

Voice: (408) 721-5582

Parity: None

Stop Bit: 1

Operation: 24 Hrs., 7 Days

COP888CLMH

Single-Chip microCMOS Microcontroller Emulator

General Description

The COP888CLMH hybrid emulator is a member of the COPSTM microcontroller family. The device is a two chip system in a dual cavity package. Within the package is the COP888CL and a UV-erasable 8k EPROM with port recreation logic. Code executes out of EPROM. The device is offered in three packages: 44-pin LDCC, 40-pin DIP, and 28-pin DIP. All packages contain transparent windows which allows the EPROM to be erased and re-programmed.

The COP888CLMH is a fully static part, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUSTM serial I/O, two 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), and two power savings modes (HALT and IDLE), both with a multi-sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The COP888CLMH operates over a voltage range of 4.5V to 5.5V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

The COP888CLMH is primarily intended as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only.

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μ s instruction cycle time
- 8192 bytes on-board EPROM
- 128 bytes on-board RAM

- Single supply operation: 4.5V–5.5V
- MICROWIRE/PLUSTM serial I/O
- WATCHDOG™ and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- Two 16-bit timers, each with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- Ten multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Two Timers each with 2 interrupts
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - Default VIS
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Versatile instruction set with true bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 LDCC with 39 I/O pins
40 DIP with 33 I/O pins
28 DIP with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Form fit and function emulation device for the COP888CL
- Real time emulation and full program debug offered by National's Development Systems

Ordering Information

Hybrid Emulator	Package Type	Part Emulated with Crystal Oscillator Option
COP888CLMHD-x	40-Pin DIP	COP888CL-XXX/N
COP888CLMHXL-x	44-Pin LDCC	COP888CL-XXX/V
COP884CLMHD-x	28-Pin DIP	COP884CL-XXX/N

x indicates crystal oscillator option; for applications requiring R/C oscillator option check with your local National Sales Representative.

Connection Diagrams

Note: The pins labeled unused must be connected to GND.

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Voltage at Any Pin	$-0.3V$ to $V_{CC} + 0.3V$
Total Current into V_{CC} Pin (Source)	100 mA
Total Current out of GND Pin (Sink)	110 mA
Storage Temperature Range	$-65^{\circ}C$ to $+140^{\circ}C$

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

The following AC and DC Electrical Characteristics are not tested but are for reference only.

DC Electrical Characteristics $0^{\circ}C \leq T_A \leq +70^{\circ}C$ unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units
Operating Voltage		4.5		5.5	V
Power Supply Ripple (Note 1)	Peak-to-Peak			$0.1 V_{CC}$	V
Supply Current (Note 2) CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			25	mA
HALT Current (Note 3)	$V_{CC} = 5.5V, CKI = 0$ MHz		250		μA
IDLE Current CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			15	mA

Reset Pulse Width		1			μs

Note 4: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

Note 5: Parameter sampled (not 100% tested).

TL/DD/10467-3

FIGURE 2. MICROWIRE/PLUS Timing

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The COP888CLMH contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input, output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. Figure 3 shows the I/O port configurations for the COP888CLMH. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

TL/DD/10467-4

FIGURE 3. I/O Port Configurations

PORT L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

The Port L supports Multi-Input Wake Up on all eight pins. L4 and L5 are used for the timer input functions T2A and T2B.

The Port L has the following alternate features:

- L0 MIWU
- L1 MIWU
- L2 MIWU
- L3 MIWU
- L4 MIWU or T2A
- L5 MIWU or T2B
- L6 MIWU
- L7 MIWU

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOUT WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin but is also used to bring the device out of HALT mode with a low to high transition. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin (crystal clock option) or general purpose input (R/C clock option), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

- G1 WDOUT (WATCHDOG and/or Clock Monitor dedicated output)
- G7 CKO (Oscillator dedicated output or general purpose input)

Port I is an eight-bit input port. The 28- and 40-pin devices do not have a full complement of Port I pins. The unavailable pins are not terminated i.e., they are floating. A read operation for these unterminated pins will return unpredictable values. The user must ensure that the software takes this into account by either masking or restricting the accesses to bit operations. The unterminated Port I pins will draw power only when addressed.

Pin Descriptions (Continued)

Port I1-13 are used for Comparator 1. Port I4-16 are used for Comparator 2.

The Port I has the following alternate features.

- 11 COMP1-IN (Comparator 1 Negative Input)
- 12 COMP1+IN (Comparator 1 Positive Input)
- 13 COMP1OUT (Comparator 1 Output)
- 14 COMP2-IN (Comparator 2 Negative Input)
- 15 COMP2+IN (Comparator 2 Positive Input)
- 16 COMP2OUT (Comparator 2 Output)

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Figure 4 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table I shows the component values required for various standard crystal values.

R/C OSCILLATOR (Special Order from Factory)

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart input.

Table II shows the variation in the oscillator frequencies as functions of the component (R and C) values.

FIGURE 4. Crystal and R/C Oscillator Diagrams

TABLE I. Crystal Oscillator Configuration,
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)
0	1	30	30-36	10
0	1	30	30-36	4
0	1	200	100-150	0.455

TABLE II. RC Oscillator Configuration,
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R (k Ω)	C (pF)	CKI Freq (MHz)	Instr. Cycle (μs)
3.3	82	2.8 to 2.2	3.6 to 4.5
5.6	100	1.5 to 1.1	6.7 to 9
6.8	100	1.1 to 0.8	9 to 12.5

Programming the COP888CLMH

Programming the COP888CLMH hybrid emulators is accomplished through the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the value specified in the following table.

Package	HALT MODE	Contents of Last Byte (Address 01FFF)
28	Enabled	6F
28	Disabled	EF
40/44	Enabled	7F
40/44	Disabled	FF

The following product codes are used by the customer order to order the duplicator board.

NSID	Description	Documentation
COP8-PRMG-PCC	Duplicator Board for 44-Pin LDCC	User Instruction Manual
COP8-PRGM-DIP	40-Pin DIP	User Instruction Manual
COP8-PRGM-28D	28-Pin DIP	User Instruction Manual

The device will also program on a Data I/O Programmer. The following table provides the programming information on a data I/O programmer.

COPs Part Number	Package Type	Family Code	Pin	Software Rev	Adapter
COP884CLMHD	28 DIP	16F	19E	V3.3	SITE 48
COP888CLMHD	40 DIP	16F	19F	V3.3	SITE 48
COP888CLMHEL	44 LDCC	16F	175	V3.2	PINSITE

ERASING THE PROGRAM MEMORY

Erasure of the program memory is achieved by removing the device from its socket and exposing the transparent window to an ultra-violet light source.

The erasure characteristics of the device are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (\AA). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000 \AA to 4000 \AA range.

Programming the COP888CLMH (Continued)

After programming, opaque labels should be placed over the window of the device to prevent temporary functional failure due to the generation of photo currents, erasure, and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the device is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The integrated dose (UV intensity \times exposure time) for erasure should be a minimum of 15 W-sec/cm².

The device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities.

TABLE III. Minimum COP888CLMH Erasure Time

Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)
15,000	20
10,000	25
5,000	50

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the dis-

tance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

Development Support

DEVELOPMENT SYSTEM

The NSC Development System is a low cost development system and emulator for all microcontroller products. These include COPs microcontrollers and the HPC family of products. The development system consists of a BRAIN Board, Personality Board and optional host software.

The purpose of the development system is to provide the user with a tool to write and assemble code, emulate code for the target microcontroller and assist in both software and hardware debugging of the system.

It is a self contained computer with its own firmware which provides for all system operation, emulation control, communication, PROM programming and diagnostic operations.

It contains three serial ports to optionally connect to a terminal, a host system, a printer or a modem, or to connect to other development systems in a multi-development system environment.

Development systems can be used in either a stand alone mode or in conjunction with a selected host system using PC-DOS communicating via a RS-232 port.

How to Order

To order a complete development package, select the section for the microcontroller to be developed and order the parts listed.

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system and additionally, provides the capability of remotely accessing the development system at a customer site.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be downloaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user is having difficulty in operating the development system he can leave messages on our electronic bulletin board, which we will respond to, or under extraordinary circumstances he can arrange for us to actually take control of his system via modem for debugging purposes.

COP888CFMH

Single-Chip microCMOS Microcontroller Emulator

General Description

The COP888CFMH hybrid emulator is a member of the COPS™ microcontroller family. The device is a two chip system in a dual cavity package. Within the package is the COP888CF and a UV-erasable 8k EPROM with port recreation logic code executes of the EPROM. This device is offered in three packages: 44-pin LDCC, 40-pin DIP and 28-pin DIP. All packages contain transparent windows which allows the EPROM to be erased and re-programmed.

The COP888CFMH is a fully static part, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUS™ serial I/O, two 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), an 8-channel, 8-bit A/D converter with both differential and single ended modes, and two power savings modes (HALT and IDLE), both with a multi-sourced wake-up/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The COP888CFMH operates over a voltage range of 4.5V to 5.5V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

The COP888CFMH is primarily intended as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only.

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μ s instruction cycle time
- 8192 bytes on-board EPROM
- 128 bytes on-board RAM
- Single supply operation: 4.5V–5.5V
- 8-Channel A/D converter with prescaler and both differential and single ended modes
- MICROWIRE/PLUS serial I/O
- WATCHDOG™ and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- Ten multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer TO
 - Two Timers each with 2 interrupts
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - Default VIS
- Two 16-bit timers, each with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Versatile instruction set with True bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 LDCC with 37 I/O pins
40 DIP with 33 I/O pins
28 DIP with 21 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Form fit and function emulation device for the COP888CF
- Real time emulation and full program debug offered by National's Development Systems

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Voltage at Any Pin	-0.3V to $V_{CC} + 0.3V$
Total Current into V_{CC} Pin (Source)	100 mA
Total Current out of GND Pin (Sink)	110 mA
Storage Temperature Range	-65°C to +140°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

The following AC and DC Electrical Characteristics are not tested but are for reference only.

DC Electrical Characteristics $0^{\circ}C \leq T_A \leq +70^{\circ}C$ unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units
Operating Voltage		4.5		5.5	V
Power Supply Ripple (Note 1)	Peak-to-Peak			0.1 V_{CC}	V
Supply Current (Note 2) CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			25	mA
HALT Current (Note 3)	$V_{CC} = 5.5V, CKI = 0$ MHz		250		μA
IDLE Current CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			15	mA
Input Levels					
RESET					
Logic High		0.8 V_{CC}			V
Logic Low				0.2 V_{CC}	V
CKI (External and Crystal Osc. Modes)					
Logic High		0.7 V_{CC}			V
Logic Low				0.2 V_{CC}	V
All Other Inputs					
Logic High		0.7 V_{CC}			V
Logic Low				0.2 V_{CC}	V
Hi-Z Input Leakage	$V_{CC} = 5.5V$	-2		+2	μA
Input Pullup Current	$V_{CC} = 5.5V$	40		250	μA
G and L Port Input Hysteresis			0.05 V_{CC}		V
Output Current Levels					
D Outputs					
Source	$V_{CC} = 4.5V, V_{OH} = 3.3V$	0.4			mA
Sink	$V_{CC} = 4.5V, V_{OL} = 1V$	10			mA
All Others					
Source (Weak Pull-Up Mode)	$V_{CC} = 4.5V, V_{OH} = 2.7V$	10		100	μA
Source (Push-Pull Mode)	$V_{CC} = 4.5V, V_{OH} = 3.3V$	0.4			mA
Sink (Push-Pull Mode)	$V_{CC} = 4.5V, V_{OL} = 0.4V$	1.6			mA
TRI-STATE Leakage	$V_{CC} = 4.5V$	-2		+2	μA

Note 1: Rate of voltage change must be less than 0.5 V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L and G ports in the TRI-STATE mode and tied to ground, all outputs low and tied to ground. If the A/D is not being used and minimum standby current is desired, V_{REF} should be tied to AGND (effectively shorting the reference resistor). The clock monitor is disabled.

DC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$ unless otherwise specified (Continued)

Parameter	Conditions	Min	Typ	Max	Units
Allowable Sink/Source Current per Pin D Outputs (Sink) All Others				15 3	mA mA
Maximum Input Current without Latchup	$T_A = 25^{\circ}\text{C}$			± 100	mA
RAM Retention Voltage, V_r	500 ns Rise and Fall Time (Min)	2			V
Input Capacitance				7	pF
Load Capacitance on D2				1000	pF

A/D Converter Specifications $V_{CC} = 5\text{V} \pm 10\%$; $(V_{SS} - 0.050\text{V}) \leq \text{Any Input} \leq (V_{CC} + 0.050\text{V})$

Reference Voltage Input	AGND = 0V	3		V_{CC}	V
Absolute Accuracy	$V_{REF} = V_{CC}$			± 1	LSB
Non-Linearity	$V_{REF} = V_{CC}$ Deviation from the best straight line			$\pm \frac{1}{2}$	LSB
Differential Non-Linearity	$V_{REF} = V_{CC}$			$\pm \frac{1}{2}$	LSB
Input Reference Resistance		1.6		4.8	k Ω
Common Mode Input Range (Note 7)		AGND		V_{REF}	V
DC Common Mode Error				$\pm \frac{1}{4}$	LSB
Off Channel Leakage Current			1		μA
On Channel Leakage Current			1		μA
A/D Clock Frequency (Note 5)		0.1		1.67	MHz
Conversion Time (Note 4)			12		A/D clock Cycles

Note 4: Conversion Time includes sample and hold time.

Note 5: See Prescaler description.

Note 6: Pins G6 and RESET are designed with a high voltage input network for factory testing. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

Note 7: For $V_{IN(-)} \geq V_{IN(+)}$ the digital output code will be 0000 0000. Two on-chip diodes are tied to each analog input. The diodes will forward conduct for analog input voltages below ground or above the V_{CC} supply. Be careful, during testing at low V_{CC} levels (4.5V), as high level analog inputs (5V) can cause this input diode to conduct—especially at elevated temperatures, and cause errors for analog inputs near full-scale. The spec allows 50 mV forward bias of either diode. This means that as long as the analog V_{IN} does not exceed the supply voltage by more than 50 mV, the output code will be correct. To achieve an absolute 0 V_{DC} to 5 V_{DC} input voltage range will therefore require a minimum supply voltage of 4.950 V_{DC} over temperature variations, initial tolerance and loading.

AC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$ unless otherwise specified

TL/DD/10464-3

FIGURE 2. MICROWIRE/PLUS Timing

Pin Descriptions

V_{CC} and GND are the power supply pins.

V_{REF} and AGND are the reference pins for the onboard A/D converter.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The COP888CFMH contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input, output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. Figure 3 shows the I/O port configurations. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

FIGURE 3. I/O Port Configurations

Port L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

The Port L supports Multi-Input Wake Up. L4 and L5 are used for the timer input functions T2A and T2B.

The Port L has the following alternate features:

- L0 MIWU (28- and 40-pin only)
- L1 MIWU (28- and 40-pin only)
- L2 MIWU
- L3 MIWU
- L4 MIWU or T2A
- L5 MIWU or T2B
- L6 MIWU
- L7 MIWU

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOUT WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin but is also used to bring the device out of HALT mode with a low to high transition. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin (crystal clock option) or general purpose input (R/C clock option), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

- G1 WDOUT (WATCHDOG and/or Clock Monitor dedicated output)
- G7 CKO (Oscillator dedicated output or general purpose input)

Port I is an eight-bit Hi-Z input port and also provides the analog inputs to the A/D Converter.

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Port C is an 8-bit I/O port.

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Oscillator Circuits (Continued)

Figure 4 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table I shows the component values required for various standard crystal values.

R/C OSCILLATOR (Special Order from Factory)

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart input.

Table II shows the variation in the oscillator frequencies as functions of the component (R and C) values.

0	1	30	30-36	10
0	1	30	30-36	4
0	1	200	100-150	0.455

TABLE II. RC Oscillator Configuration,
 $T_A = 25^\circ\text{C}, V_{CC} = 5\text{V}$

R (k Ω)	C (pF)	CKI Freq (MHz)	Instr. Cycle (μs)
3.3	82	2.8 to 2.2	3.6 to 4.5
5.6	100	1.5 to 1.1	6.7 to 9
6.8	100	1.1 to 0.8	9 to 12.5

Programming the COP888CFMH

Programming the COP888CFMH hybrid emulators is accomplished with the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the value specified in the following table.

TABLE III

Package	HALT Mode	Contents of Last Byte (Address 01FFF)
28	Enabled	6F
28	Disabled	EF
40/44	Enabled	7F
40/44	Disabled	FF

The following product codes are used by the customer order to order the duplicator board.

NSID	Description	Documentation
COP8-PRGM-PCC	Duplicator Board for 44-Pin LDCC	User Instruction Manual
COP8-PRGM-DIP	40-Pin DIP	User Instruction Manual
COP8-PRGM-28D	28-Pin DIP	User Instruction Manual

The device will also program on a Data I/O Programmer.

The following table provides the programming information on a Data I/O Programmer.

COPs Part Number	Package Type	Family Code	Pin	Software Rev	Adapter
COP884CFMHD	28 DIP	16F	19E	V3.3	SITE 48
COP888CFMHD	40 DIP	16F	19F	V3.3	SITE 48
COP888CFMHEL	44 LDCC	16F	175	V3.2	PINSITE

ERASING THE PROGRAM MEMORY

Erasure of the program memory is achieved by removing the device from its socket and exposing the transparent window to an ultra-violet light source.

The erasure characteristics of the device are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000Å. It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å to 4000Å range.

After programming, opaque labels should be placed over the window of the device to prevent temporary functional failure due to the generation of photo currents, erasure, and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the device is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The integrated dose (UV intensity X exposure time) for erasure should be a minimum of 15 W-sec/cm².

The device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities.

TABLE IV. Minimum COP888CFMH Erasure Time

Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)
15,000	20
10,000	25
5,000	50

Development Support

Development Tools Selection Table

Microcontroller	Order Part Number	Description	Includes	Manual Number
COP888	MOLE-BRAIN	Brain Board	Brain Board Users Manual	420408188-001
	MOLE-COP8-PB2	Personality Board	COP888 Personality Board Users Manual	420420084-001
	MOLE-COP8-IBM	Assembler Software for IBM	COP800 Software Users Manual and Software Disk PC-DOS Communications Software Users Manual	424410527-001 420040416-001
	420411060-001	Programmer's Manual		420411060-01

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

DEVELOPMENT SYSTEM

The NSC Development System is a low cost development system and emulator for all microcontroller products. These include COPs microcontrollers and the HPC family of products. The development system consists of a BRAIN Board, Personality Board and optional host software.

The purpose of the development system is to provide the user with a tool to write and assemble code, emulate code for the target microcontroller and assist in both software and hardware debugging of the system.

It is a self contained computer with its own firmware which provides for all system operation, emulation control, communication, PROM programming and diagnostic operations.

It contains three serial ports to optionally connect to a terminal, a host system, a printer or a modem, or to connect to other development systems in a multi-development system environment.

Development system can be used in either a stand alone mode or in conjunction with a selected host system using PC-DOS communicating via a RS-232 port.

How to Order

To order a complete development package, select the section for the microcontroller to be developed and order the parts listed.

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system and additionally, provides the capability of remotely accessing the development system at a customer site.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user is having difficulty in operating the development system, he can leave messages on our electronic bulletin board, which we will respond to, or under extraordinary circumstances he can arrange for us to actually take control of his system via modem for debugging purposes.

PRELIMINARY

COP888CGMH/COP884CGMH and COP888EGMH microCMOS Microcontroller Emulator

General Description

The COP888CGMH and COP888EGMH hybrid emulators are members of the COP8™ microcontroller family. The device is a two chip system in a dual cavity package. Within the package is the COP888CG or COP888EG and a UV-erasable 8k EPROM with port recreation logic. Code executes out of EPROM. The device is offered in the following packages: COP888CG and COP888EG are in 44-pin LDCC, 40-pin DIP, and COP884CGMH in 28-pin DIP. All packages contain transparent windows which allow the EPROM to be erased and re-programmed.

The COP888CGMH/COP888EGMH are fully static, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUSTM serial I/O, three 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), full duplex UART, two comparators, and two power savings modes (HALT and IDLE), both with a multi-sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The device operates over a voltage range of 4.5V to 5.5V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μ s per instruction rate.

These devices are primarily intended as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only.

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μ s instruction cycle time
- 8192 bytes on-board EPROM
- 192 bytes on-board RAM for COP888CGMH; 256 bytes for COP888EGMH
- Single supply operation: 4.5V–5.5V
- Full duplex UART
- Two analog comparators
- MICROWIRE/PLUS serial I/O
- WATCHDOG and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- Three 16-bit timers, each with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- Fourteen multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Two Timers each with 2 interrupts
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - UART (2)
 - Default VIS
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Versatile instruction set with true bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 LDCC with 39 I/O pins
40 DIP with 35 I/O pins
28 DIP with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Form fit and function emulation device for the COP888CG and COP888EG
- Real time emulation and full program debug offered by National's Development Systems

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Voltage at Any Pin	-0.3V to $V_{CC} + 0.3V$
Total Current into V_{CC} Pin (Source)	100 mA
Total Current out of GND Pin (Sink)	110 mA
Storage Temperature Range	-65°C to +140°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

The following AC and DC Electrical Characteristics are not tested but are for reference only.

DC Electrical Characteristics $0^{\circ}C \leq T_A \leq +70^{\circ}C$ unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units
Operating Voltage		4.5		5.5	V
Power Supply Ripple (Note 1)	Peak-to-Peak			0.1 V_{CC}	V
Supply Current (Note 2) CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			25	mA
HALT Current (Note 3)	$V_{CC} = 5.5V, CKI = 0$ MHz		250		μA
IDLE Current CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			15	mA
Input Levels RESET Logic High Logic Low CKI (External and Crystal Osc. Modes) Logic High Logic Low All Other Inputs Logic High Logic Low		0.8 V_{CC} 0.7 V_{CC} 0.7 V_{CC}		0.2 V_{CC} 0.2 V_{CC} 0.2 V_{CC}	V V V V V V

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The COP888CGMH/COP888EGMH contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input, output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. Figure 3 shows the I/O port configurations. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

TL/DD/10425-6

FIGURE 3. I/O Port Configurations

Port L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

The Port L supports Multi-Input Wake Up on all eight pins. L1 is used for the UART external clock. L2 and L3 are used for the UART transmit and receive. L4 and L5 are used for the timer input functions T2A and T2B. L6 and L7 are used for the timer input functions T3A and T3B.

The Port L has the following alternate features:

- L0 MIWU
- L1 MIWU or CKX
- L2 MIWU or TDX
- L3 MIWU or RDX
- L4 MIWU or T2A
- L5 MIWU or T2B
- L6 MIWU or T3A
- L7 MIWU or T3B

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOUR WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin but is also used to bring the device out of HALT mode with a low to high transition. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

Pin Descriptions (Continued)

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin (crystal clock option) or general purpose input (R/C clock option), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

- G1 WDOU (WATCHDOG and/or Clock Monitor dedicated output)
- G7 CKO (Oscillator dedicated output or general purpose input)

Port I is an 8-bit port. Port I1–I3 are used for Comparator 1. Port I4–I6 are used for Comparator 2.

The Port I has the following alternate features.

- I1 COMP1–IN (Comparator 1 Negative Input)
- I2 COMP1+IN (Comparator 1 Positive Input)
- I3 COMP1OUT (Comparator 1 Output)
- I4 COMP2–IN (Comparator 2 Negative Input)
- I5 COMP2+IN (Comparator 2 Positive Input)
- I6 COMP2OUT (Comparator 2 Output)

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Port C is an 8-bit I/O port.

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Figure 4 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table I shows the component values required for various standard crystal values.

R/C OSCILLATOR (SPECIAL ORDER FROM FACTORY)

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart input.

Table II shows the variation in the oscillator frequencies as functions of the component (R and C) values.

FIGURE 4. Crystal and R/C Oscillator Diagrams

TABLE I. Crystal Oscillator Configuration,
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)
0	1	30	30–36	10
0	1	30	30–36	4
0	1	200	100–150	0.455

TABLE II. RC Oscillator Configuration,
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R (k Ω)	C (pF)	CKI Freq (MHz)	Instr. Cycle (μs)
3.3	82	2.8 to 2.2	3.6 to 4.5
5.6	100	1.5 to 1.1	6.7 to 9
6.8	100	1.1 to 0.8	9 to 12.5

Programming the COP888CGMH/ COP888EGMH

Programming the COP888CGMH/COP888EGMH hybrid emulators is accomplished through the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the value specified in the following table.

Programming the COP888CGMH/ COP888EGMH (Continued)

TABLE III

Package	HALT Mode	Contents of Last Byte (Address 01FFF)
28	Enabled	6F
28	Disabled	EF
40/44	Enabled	7F
40/44	Disabled	FF

ERASING THE PROGRAM MEMORY

Erasure of the program memory is achieved by removing the device from its socket and exposing the transparent window to an ultra-violet light source.

The erasure characteristics of the device are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (Å). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å to 4000Å range.

After programming, opaque labels should be placed over the window of the device to prevent temporary functional failure due to the generation of photo currents, erasure, and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the device is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The intergrated dose (UV intensity × exposure time) for erasure should be a minimum of 15 W-sec/cm².

The device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities.

TABLE IV. Minimum COP888CGMH/COP888EGMH Erasure Time

Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)
15,000	20
10,000	25
5,000	50

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features

high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32k Bytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read & write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER'S performance analyzer offers a resolution of better than 6 μs. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bargraph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2k Baud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	Metalink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS 232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 Macro Cross Assembler for IBM PC/XT, AT or Compatible	424410527-001

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system and additionally, provides the capability of remotely accessing the MOLE development system at a customer site.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
 Dial-A-Helper Users Manual
 Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user is having difficulty in operating the development system, he can leave messages on our electronic bulletin board, which we will respond to, or under extraordinary circumstances he can arrange for us to actually take control of his system via modem for debugging purposes.

Voice: (408) 721-5582

 Baud: 300 or 1200 Baud
 Set-up: Length: 8-Bit
 Parity: None
 Stop Bit: 1
 Operation: 24 Hrs., 7 Days

TL/DD/10425-11

COP820CJM/COP822CJM Single-Chip microCMOS Microcontroller

General Description

The COP820CJM and COP822CJM hybrid emulators are members of the COPSM microcontroller family. Each device is a two chip system in a dual cavity package. Within the package is the COP820CJ and a UV-erasable 8k EPROM with port recreation logic. The code executes out of the EPROM. The devices (offered in 28-pin DIP and 20-pin DIP packages) contain transparent windows which allow the EPROM to be erased and reprogrammed. The devices are fully static parts, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRETM serial I/O, a 16-bit timer/counter with capture register, a multi-sourced interrupt, Comparator, WATCHDOGTM Timer, Modulator/Timer, and Multi-Input Wakeup. Each I/O pin has software selectable options to adapt the device to the specific application. The device operates over a voltage range of 4.5V to 6.0V. High throughput is achieved with an efficient, regular instruction set operating at a 1 μ s per instruction rate.

COP820CJM and COP822CJM are intended primarily as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only. These devices do not emulate the Brown Out feature.

Features

- Form, fit and function emulation device for the COP820CJ/COP822CJ
- Fully static CMOS
- 1 μ s instruction time
- Single supply operation: 4.5V to 6.0V
- 8191 x 8 on-chip ROM
- 64 bytes on-chip RAM
- WATCHDOG Timer
- Comparator
- Modulator/Timer (High speed PWM Timer for IR Transmission)
- Multi-Input Wakeup (on the 8-bit Port L)
- 4 high current I/O pins with 15 mA sink capability
- MICROWIRE/PLUSTSM serial I/O
- 16-bit read/write timer operates in a variety of modes
 - Timer with 16-bit auto reload register
 - 16-bit external event counter
 - Timer with 16-bit capture register (selectable edge)
- Multi-source interrupt
 - External interrupt with selectable edge
 - Timer interrupt or capture interrupt
 - Software interrupt
- 8-bit stack pointer (stack in RAM)
- Powerful instruction set, most instructions single byte
- BCD arithmetic instructions
- 28- and 20-pin DIP
- Software selectable I/O options (TRI-STATE[®], push-pull, weak pull-up)
- Schmitt trigger inputs on Port G and Port L

Ordering Information

Hybrid Emulator	Package Type	Part Emulated
COP820CJMHD-X	28-Pin DIP	COP820CJ-XXX/N
COP822CJMHD-X	20-Pin DIP	COP822CJ-XXX/N

Note: X corresponds to clock options.

- X = 1,2 or 3.

- 2 = External \div 10,
- 3 = R/C \div 10

COP820CJMH/COP822CJMH**Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7.0V
Reset (V_{PP}) and G6 (ME)	-0.3V to 14V
Voltage at any Pin	-0.3V to V_{CC} + 0.3V
Total Current into V_{CC} pin (Source)	80 mA
Total Current out of GND pin (sink)	80 mA
Storage Temperature Range	-65°C to +150°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur.

DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

The following AC and DC Electrical Characteristics are not tested but are for reference only.

DC Electrical Characteristics $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units
Operating Voltage	Brown Out Disabled	4.5		6.0	V
Power Supply Ripple 1 (Note 1)	Peak to Peak			$0.1 V_{CC}$	V
Supply Current (Note 2)

L4-L7 Output Sink	$V_{CC} = 4.5V, V_{OL} = 2.5V$	15			mA
All Others					
Source (Weak Pull-up Mode)	$V_{CC} = 4.5V, V_{OH} = 3.2V$	10		110	μA
Source (Push-pull Mode)	$V_{CC} = 4.5V, V_{OH} = 3.8V$	0.4			mA
Sink (Push-pull Mode)	$V_{CC} = 4.5V, V_{OL} = 0.4V$	1.6			mA
TRI-STATE Leakage		-2.0		+2.0	μA
Allowable Sink/Source Current Per Pin					
D Outputs				15	mA
L4-L7 (Sink)				20	mA
All Others				3	mA

DC Electrical Characteristics $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ unless otherwise specified (Continued)

Parameter	Conditions	Min	Typ	Max	Units
Maximum Input Current without Latchup (Note 4)	Room Temperature			± 100	mA
RAM Retention Voltage, V_r	500 ns Rise and Fall Time (Min)	2.0			V
Input Capacitance				7	pF
Load Capacitance on D2				1000	pF

Note 1: Rate of voltage change must be less than 10 V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and crystal configurations. HALT test conditions: L and G0..G5 ports configured as outputs and set high. The D port set to zero. All inputs tied to V_{CC} . The comparator and the Brown Out circuits are disabled.

Note 4: Pins G6 and $\overline{\text{RESET}}$ are designed with a high voltage input network. These pins allow input voltages greater than V_{CC} and the pins will have sink current to V_{CC} when biased at voltages greater than V_{CC} (the pins do not have source current when biased at a voltage below V_{CC}). The effective resistance to V_{CC} is 750 Ω (typical). These two pins will not latch up. The voltage at the pins must be limited to less than 14V.

AC Electrical Characteristics $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ unless otherwise specified

Pin Description

V_{CC} and **GND** are the power supply pins.

CKI is the clock input. This can come from an external source, a R/C generated oscillator or a crystal (in conjunction with CKO). See Oscillator description.

RESET is the master reset input. See Reset description.

PORT I is a 4-bit Hi-Z input port.

PORT L is an 8-bit I/O port.

There are two registers associated with the L port: a data register and a configuration register. Therefore, each L

I/O bit can be individually configured under software control as shown below:

Port L Config.	Port L Data	Port L Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input with Weak Pull-up
1	0	Push-pull Zero Output
1	1	Push-pull One Output

Three data memory address locations are allocated for this port, one each for data register [00D0], configuration register [00D1] and the input pins [00D2].

Port L has the following alternate features:

L0 MIWU or CMPOUT

L1 MIWU or CMPIN-

L2 MIWU or CMPIN+

L3 MIWU

L4 MIWU (high sink current capability)

L5 MIWU (high sink current capability)

L6 MIWU (high sink current capability)

L7 MIWU or MODOUT (high sink current capability)

The selection of alternate Port L function is done through registers WKEN [00C9] to enable MIWU and CNTRL2 [00CC] to enable comparator and modulator.

All eight L-pins have Schmitt Triggers on their inputs.

PORT G is an 8-bit port with 6 I/O pins (G0-G5) and 2 input pins (G6, G7).

All eight G-pins have Schmitt Triggers on the inputs.

There are two registers associated with the G port: a data register and a configuration register. Therefore each G port bit can be individually configured under software control as shown below:

Port G Config.	Port G Data	Port G Setup
0	0	Hi-Z Input (TRI-STATE)
0	1	Input with Weak Pull-up
1	0	Push-pull Zero Output
1	1	Push-pull One Output

Three data memory address locations are allocated for this port, one for data register [00D3], one for configuration register [00D5] and one for the input pins [00D6]. Since G6 and G7 are Hi-Z input only pins, any attempt by the user to configure them as outputs by writing a one to the configuration register will be disregarded. Reading the G6 and G7 configuration bits will return zeros. Note that the device will be placed in the Halt mode by writing a "1" to the G7 data bit.

Six pins of Port G have alternate features:

G0 INTR (an external interrupt)

G3 TIO (timer/counter input/output)

G4 SO (MICROWIRE serial data output)

G5 SK (MICROWIRE clock I/O)

G6 SI (MICROWIRE serial data input)

G7 CKO crystal oscillator output (selected by mask option) or HALT restart input/general purpose input (if clock option is R/C or external clock)

Pin Description (Continued)

Pins G1 and G2 currently do not have any alternate functions.

The selection of alternate Port G functions are done through registers PSW [00EF] to enable external interrupt and CNTRL1 [00EE] to select TIO and MICROWIRE operations.

PORT D is a four bit output port that is preset when RESET goes low. One data memory address location is allocated for the data register [00DC].

Oscillator Circuits

EXTERNAL OSCILLATOR

CKI can be driven by an external clock signal provided it meets the specified duty cycle, rise and fall times, and input levels. CKO is available as a general purpose input G7 and/or Halt control.

CRYSTAL OSCILLATOR

By selecting CKO as a clock output, CKI and CKO can be connected to create a crystal controlled oscillator. Table I shows the component values required for various standard crystal values.

R/C OSCILLATOR

By selecting CKI as a single pin oscillator, CKI can make a R/C oscillator. CKO is available as a general purpose input and/or HALT control. Table II shows variation in the oscillator frequencies as functions of the component (R and C) values.

TL/DD/11373-4

FIGURE 3. Clock Oscillator Configurations

TABLE I. Crystal Oscillator Configuration

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq. (MHz)	Conditions
0	1	30	30-36	10	$V_{CC} = 5V$
0	1	30	30-36	4	$V_{CC} = 5V$
5.6	1	100	100-156	0.455	$V_{CC} = 5V$

TABLE II. RC Oscillator Configuration (Part-To-Part Variation)

R (k Ω)	C (pF)	CK1 Freq. (MHz)	Instr. Cycle (μs)	Conditions
3.3	82	2.2 to 2.7	3.7 to 4.6	$V_{CC} = 5V$
5.6	100	1.1 to 1.3	7.4 to 9.0	$V_{CC} = 5V$
6.8	100	0.9 to 1.1	8.8 to 10.8	$V_{CC} = 5V$

Programming the COP820CJMH/ COP822CJMH

Programming the hybrid emulators is accomplished through the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the NSC development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the proper value specified in the following table

Device	Package Type	Contents of Last Byte (Address 01FFF)
COP820CJMH	28 DIP	6F
COP822CJMH	20 DIP	E7

ERASING THE PROGRAM MEMORY

Erasure of the EPROM program memory is achieved by removing the device from its socket and exposing the transparent window to an ultra-violet light source.

The erasure characteristics of the device are such that the erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (Å). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å to 4000 range.

After programming, opaque labels should be placed over the window of the device to prevent temporary functional failure due to the generation of photo currents, erasure, and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the devices is exposure to short wave ultraviolet light which as a wavelength of 2537Å. The integrated dose (UV intensity \times exposure time) for erasure should be a minimum of 15 w-sec/cm².

The device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities.

Minimum Erasure Time		
Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)	
	28-Pin Package	20-Pin Package
15,000	20	40
10,000	25	50
5,000	50	100

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kBytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read and write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER's performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bargraph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down-menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2 kBAud serial link keeps typical program download time to under 3 seconds.

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	MetaLink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS 232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Development Support (Continued)**Probe Card Ordering Information**

Part Number	Package	Voltage Range	Emulates
MH-820CJ20D5PC	20 DIP	4.5V-5.5V	COP822CJ
MHW-820CJ20DWPC	20 DIP	2.3V-6.0V	COP822CJ

MHW-820CJ28DWPC	28 DIP	2.3V-6.0V	COP820CJ

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE-COP8-IBM	COP8 macro cross assembler for IBM® PC-XT®, PC-AT® or compatible	424410527-001

SINGLE CHIP EMULATOR

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

COP8-SCRM-SBX	Scrambler board for 28 LCC sockets	COP820CJMHEA
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler board	COP822CJMHD COP820CJMHD

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications Group. The Dial-A-Helper is an Electronic Bulletin Board information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

If the user has a PC with a communications package then files from the FILE SECTION can be down-loaded to disk for later use.

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factory applications support. If a user has questions, he can leave messages on our electronic bulletin board.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 baud

Setup: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs. 7 Days

COP888CSMH microCMOS Microcontroller Emulator

General Description

The COP888CSMH hybrid emulators is a members of the COPS™ microcontroller family. The device is a two chip system in a dual cavity package. Within the package is the COP888CS and a UV-erasable 8k EPROM with port recreation logic. Code executes out of EPROM. The device is offered in the following packages: 44-pin LDCC, 40-pin DIP, and 28-pin DIP. All packages contain transparent windows which allow the EPROM to be erased and re-programmed.

The COP888CSMH is a fully static part, fabricated using double-metal silicon gate microCMOS technology. Features include an 8-bit memory mapped architecture, MICROWIRE/PLUSTM serial I/O, one 16-bit timer/counters supporting three modes (Processor Independent PWM generation, External Event counter, and Input Capture mode capabilities), full duplex UART, one comparator, and two power savings modes (HALT and IDLE), both with a multi-sourced wakeup/interrupt capability. This multi-sourced interrupt capability may also be used independent of the HALT or IDLE modes. Each I/O pin has software selectable configurations. The COP888CSMH operates over a voltage range of 4.5V to 5.5V. High throughput is achieved with an efficient, regular instruction set operating at a maximum of 1 μs per instruction rate.

These COP888CSMH is primarily intended as a prototyping design tool. The Electrical Performance Characteristics are not tested but are included for reference only.

Features

- Low cost 8-bit microcontroller
- Fully static CMOS, with low current drain
- Two power saving modes: HALT and IDLE
- 1 μs instruction cycle time
- 8192 bytes on-board EPROM
- 192 bytes on-board RAM
- Single supply operation: 4.5V–5.5V

- Full duplex UART
- One analog comparator
- MICROWIRE/PLUS serial I/O
- WATCHDOG and Clock Monitor logic
- Idle Timer
- Multi-Input Wakeup (MIWU) with optional interrupts (8)
- One 16-bit timer, with two 16-bit registers supporting:
 - Processor Independent PWM mode
 - External Event counter mode
 - Input Capture mode
- Ten multi-source vectored interrupts servicing
 - External Interrupt
 - Idle Timer T0
 - Timer (2)
 - MICROWIRE/PLUS
 - Multi-Input Wake Up
 - Software Trap
 - UART (2)
 - Default VJS
- 8-bit Stack Pointer SP (stack in RAM)
- Two 8-bit Register Indirect Data Memory Pointers (B and X)
- Versatile instruction set with true bit manipulation
- Memory mapped I/O
- BCD arithmetic instructions
- Package: 44 LDCC with 39 I/O pins
40 DIP with 35 I/O pins
28 DIP with 23 I/O pins
- Software selectable I/O options
 - TRI-STATE® Output
 - Push-Pull Output
 - Weak Pull Up Input
 - High Impedance Input
- Schmitt trigger inputs on ports G and L
- Form fit and function emulation device for the COP888CS
- Real time emulation and full program debug offered by National's Development Systems

Ordering Information

Hybrid Emulator	Package Type	Part Emulated with Crystal Oscillator Option
COP888CSMHD-X	40-Pin DIP	COP888CS-XXX/N
COP888CSMHEL-X	44-Pin LDCC	COP888CS-XXX/V
COP884CSMHD-X	28-Pin DIP	COP884CS-XXX/N

X indicates Crystal Option: for applications requiring R/C oscillator option check with your local sales representative.

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	7V
Voltage at Any Pin	-0.3V to $V_{CC} + 0.3V$
Total Current into V_{CC} Pin (Source)	100 mA
Total Current out of GND Pin (Sink)	110 mA
Storage Temperature Range	-65°C to +140°C

Note: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications are not ensured when operating the device at absolute maximum ratings.

The following AC and DC Electrical Characteristics are not tested but are for reference only.

DC Electrical Characteristics $0^{\circ}C \leq T_A \leq +70^{\circ}C$ unless otherwise specified

Parameter	Conditions	Min	Typ	Max	Units
Operating Voltage		4.5		5.5	V
Power Supply Ripple (Note 1)	Peak-to-Peak			$0.1 V_{CC}$	V
Supply Current (Note 2) CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			25	mA
HALT Current (Note 3)	$V_{CC} = 5.5V, CKI = 0 \text{ MHz}$		250		μA
IDLE Current CKI = 10 MHz	$V_{CC} = 5.5V, t_c = 1 \mu s$			15	mA
Input Levels RESET					
Logic High		$0.8 V_{CC}$			V
Logic Low				$0.2 V_{CC}$	V
CKI (External and Crystal Osc. Modes)					
Logic High		$0.7 V_{CC}$			V
Logic Low				$0.2 V_{CC}$	V
All Other Inputs					
Logic High		$0.7 V_{CC}$			V
Logic Low				$0.2 V_{CC}$	V
Hi-Z Input Leakage	$V_{CC} = 5.5V$	-2		+2	μA
Input Pullup Current	$V_{CC} = 5.5V$	40		250	μA
G and L Port Input Hysteresis				$0.35 V_{CC}$	V
Output Current Levels					
D Outputs					
Source	$V_{CC} = 4.5V, V_{OH} = 3.3V$	0.4			mA
Sink	$V_{CC} = 4.5V, V_{OL} = 1V$	10			mA
All Others					
Source (Weak Pull-Up Mode)	$V_{CC} = 4.5V, V_{OH} = 2.7V$	10		100	μA
Source (Push-Pull Mode)	$V_{CC} = 4.5V, V_{OH} = 3.3V$	0.4			mA
Sink (Push-Pull Mode)	$V_{CC} = 4.5V, V_{OL} = 0.4V$	1.6			mA
TRI-STATE Leakage	$V_{CC} = 4.5V$	-2		+2	μA

Note 1: Rate of voltage change must be less than 0.5 V/ms.

Note 2: Supply current is measured after running 2000 cycles with a square wave CKI input, CKO open, inputs at rails and outputs open.

Note 3: The HALT mode will stop CKI from oscillating in the RC and the Crystal configurations. Test conditions: All inputs tied to V_{CC} , L and G ports in the TRI-STATE mode and tied to ground, all outputs low and tied to ground. The comparators and Clock Monitor are disabled.

DC Electrical Characteristics $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$ unless otherwise specified (Continued)

Pin Descriptions

V_{CC} and GND are the power supply pins.

CKI is the clock input. This can come from an R/C generated oscillator, or a crystal oscillator (in conjunction with CKO). See Oscillator Description section.

RESET is the master reset input. See Reset Description section.

The COP888CSMH contains three bidirectional 8-bit I/O ports (C, G and L), where each individual bit may be independently configured as an input, output or TRI-STATE under program control. Three data memory address locations are allocated for each of these I/O ports. Each I/O port has two associated 8-bit memory mapped registers, the CONFIGURATION register and the output DATA register. A memory mapped address is also reserved for the input pins of each I/O port. Figure 3 shows the I/O port configurations for the COP888CSMH. The DATA and CONFIGURATION registers allow for each port bit to be individually configured under software control as shown below:

CONFIGURATION Register	DATA Register	Port Set-Up
0	0	Hi-Z Input (TRI-STATE Output)
0	1	Input with Weak Pull-Up
1	0	Push-Pull Zero Output
1	1	Push-Pull One Output

TL/DD/11387-5

FIGURE 3. I/O Port Configurations

Port L is an 8-bit I/O port. All L-pins have Schmitt triggers on the inputs.

The Port L supports Multi-Input Wake Up on all eight pins. L1 is used for the UART external clock. L2 and L3 are used for the UART transmit and receive.

The Port L has the following alternate features:

- L0 MIWU
- L1 MIWU or CKX
- L2 MIWU or TDX
- L3 MIWU or RDX
- L4 MIWU
- L5 MIWU
- L6 MIWU
- L7 MIWU

Port G is an 8-bit port with 5 I/O pins (G0, G2–G5), an input pin (G6), and two dedicated output pins (G1 and G7). Pins G0 and G2–G6 all have Schmitt Triggers on their inputs. Pin G1 serves as the dedicated WDOOUT WATCHDOG output, while pin G7 is either input or output depending on the oscillator mask option selected. With the crystal oscillator option selected, G7 serves as the dedicated output pin for the CKO clock output. With the single-pin R/C oscillator mask option selected, G7 serves as a general purpose input pin but is also used to bring the device out of HALT mode with a low to high transition. There are two registers associated with the G Port, a data register and a configuration register. Therefore, each of the 5 I/O bits (G0, G2–G5) can be individually configured under software control.

Pin Descriptions (Continued)

Since G6 is an input only pin and G7 is the dedicated CKO clock output pin (crystal clock option) or general purpose input (R/C clock option), the associated bits in the data and configuration registers for G6 and G7 are used for special purpose functions as outlined below. Reading the G6 and G7 data bits will return zeros.

Note that the chip will be placed in the HALT mode by writing a "1" to bit 7 of the Port G Data Register. Similarly the chip will be placed in the IDLE mode by writing a "1" to bit 6 of the Port G Data Register.

Writing a "1" to bit 6 of the Port G Configuration Register enables the MICROWIRE/PLUS to operate with the alternate phase of the SK clock. The G7 configuration bit, if set high, enables the clock start up delay after HALT when the R/C clock configuration is used.

	Config Reg.	Data Reg.
G7	CLKDLY	HALT
G6	Alternate SK	IDLE

Port G has the following alternate features:

- G0 INTR (External Interrupt Input)
- G2 T1B (Timer T1 Capture Input)
- G3 T1A (Timer T1 I/O)
- G4 SO (MICROWIRE Serial Data Output)
- G5 SK (MICROWIRE Serial Clock)
- G6 SI (MICROWIRE Serial Data Input)

Port G has the following dedicated functions:

- G1 WDOUT (WATCHDOG and/or Clock Monitor dedicated output)
- G7 CKO (Oscillator dedicated output or general purpose input)

Port I is an 8-bit port. Port I1–I3 are used for Comparator 1. Port I4–I6 are used for Comparator 2.

The Port I has the following alternate features.

- I1 COMP1–IN (Comparator 1 Negative Input)
- I2 COMP1+IN (Comparator 1 Positive Input)
- I3 COMP1OUT (Comparator 1 Output)
- I4 COMP2–IN (Comparator 2 Negative Input)
- I5 COMP2+IN (Comparator 2 Positive Input)
- I6 COMP2OUT (Comparator 2 Output)

Port D is an 8-bit output port that is preset high when RESET goes low. The user can tie two or more D port outputs together in order to get a higher drive.

Port C is an 8-bit I/O port.

Oscillator Circuits

The chip can be driven by a clock input on the CKI input pin which can be between DC and 10 MHz. The CKO output clock is on pin G7 (crystal configuration). The CKI input frequency is divided down by 10 to produce the instruction cycle clock ($1/t_c$).

Figure 4 shows the Crystal and R/C diagrams.

CRYSTAL OSCILLATOR

CKI and CKO can be connected to make a closed loop crystal (or resonator) controlled oscillator.

Table I shows the component values required for various standard crystal values.

R/C OSCILLATOR (SPECIAL ORDER FROM FACTORY)

By selecting CKI as a single pin oscillator input, a single pin R/C oscillator circuit can be connected to it. CKO is available as a general purpose input, and/or HALT restart input.

Table II shows the variation in the oscillator frequencies as functions of the component (R and C) values.

FIGURE 4. Crystal and R/C Oscillator Diagrams

TABLE I. Crystal Oscillator Configuration,
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R1 (k Ω)	R2 (M Ω)	C1 (pF)	C2 (pF)	CKI Freq (MHz)
0	1	30	30–36	10
0	1	30	30–36	4
0	1	200	100–150	0.455

TABLE II. RC Oscillator Configuration,
 $T_A = 25^\circ\text{C}$, $V_{CC} = 5\text{V}$

R (k Ω)	C (pF)	CKI Freq (MHz)	Instr. Cycle (μs)
3.3	82	2.2 to 2.7	3.7 to 4.6
5.6	100	1.1 to 1.3	7.4 to 9
6.8	100	0.9 to 1.1	8.8 to 10.8

Programming the COP888CSMH

Programming the COP888CSMH hybrid emulators is accomplished through the duplicator board which is a stand alone programmer capable of supporting different package types. It works in conjunction with a pre-programmed EPROM (either via the development system or a standard programmer) holding the application program. The duplicator board essentially copies the information in the EPROM into the hybrid emulator.

The last byte of program memory (EPROM location 01FFF Hex) must contain the value specified in the following table.

Programming the COP888CSMH

(Continued)

TABLE III

Package	HALT Mode	Contents of Last Byte (Address 01FFF)
28	Enabled	6F
28	Disabled	EF
40/44	Enabled	7F
40/44	Disabled	FF

ERASING THE PROGRAM MEMORY

Erasure of the program memory is achieved by removing the device from its socket and exposing the transparent window to an ultra-violet light source.

The erasure characteristics of the device are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (Å). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å to 4000Å range.

After programming, opaque labels should be placed over the window of the device to prevent temporary functional failure due to the generation of photo currents, erasure, and excessive HALT current. Note that the device will also draw more current than normal (especially in HALT mode) when the window of the device is not covered with an opaque label.

The recommended erasure procedure for the device is exposure to short wave ultraviolet light which has a wavelength of 2537Å. The integrated dose (UV intensity \times exposure time) for erasure should be a minimum of 15 W-sec/cm².

The device should be placed within one inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. The following table shows the minimum erasure time for various light intensities.

TABLE IV. Minimum COP888CSMH Erasure Time

Light Intensity (Micro-Watts/cm ²)	Erasure Time (Minutes)
15,000	20
10,000	25
5,000	50

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increases as the square of the distance. Lamps lose intensity as they age. When a lamp has aged, the system should be checked to make certain that adequate UV dosages are being applied for full erasure.

Development Support

IN-CIRCUIT EMULATOR

The MetaLink iceMASTER™-COP8 Model 400 In-Circuit Emulator for the COP8 family of microcontrollers features high-performance operation, ease of use, and an extremely flexible user-interface for maximum productivity. Interchangeable probe cards, which connect to the standard common base, support the various configurations and packages of the COP8 family.

The iceMASTER provides real time, full speed emulation up to 10 MHz, 32 kbytes of emulation memory and 4k frames of trace buffer memory. The user may define as many as 32k trace and break triggers which can be enabled, disabled, set or cleared. They can be simple triggers based on code or address ranges or complex triggers based on code address, direct address, opcode value, opcode class or immediate operand. Complex breakpoints can be ANDed and ORed together. Trace information consists of address bus values, opcodes and user selectable probe clips status (external event lines). The trace buffer can be viewed as raw hex or as disassembled instructions. The probe clip bit values can be displayed in binary, hex or digital waveform formats.

During single-step operation the dynamically annotated code feature displays the contents of all accessed (read & write) memory locations and registers, as well as flow-of-control direction change markers next to each instruction executed.

The iceMASTER'S performance analyzer offers a resolution of better than 6 μ s. The user can easily monitor the time spent executing specific portions of code and find "hot spots" or "dead code". Up to 15 independent memory areas based on code address or label ranges can be defined. Analysis results can be viewed in bargraph format or as actual frequency count.

Emulator memory operations for program memory include single line assembler, disassembler, view, change and write to file. Data memory operations include fill, move, compare, dump to file, examine and modify. The contents of any memory space can be directly viewed and modified from the corresponding window.

The iceMASTER comes with an easy to use windowed interface. Each window can be sized, highlighted, color-controlled, added, or removed completely. Commands can be accessed via pull-down menus and/or redefinable hot keys. A context sensitive hypertext/hyperlinked on-line help system explains clearly the options the user has from within any window.

The iceMASTER connects easily to a PC via the standard COMM port and its 115.2 kBaud serial link keeps typical program download time to under 3 seconds.

Development Support (Continued)

The following tables list the emulator and probe cards ordering information.

Emulator Ordering Information

Part Number	Description
IM-COP8/400	Metalink base unit in-circuit emulator for all COP8 devices, symbolic debugger software and RS/232 serial interface cable
MHW-PS3	Power Supply 110V/60 Hz
MHW-PS4	Power Supply 220V/50 Hz

Probe Card Ordering Information

Part Number	Package	Voltage Range	Emulates
MHW-884CS28D5PC	28 DIP	4.5V-5.5V	COP884CS
MHW-884CS28DWPC	28 DIP	2.5V-6.0V	COP884CS
MHW-888CS40D5PC	40 DIP	4.5V-5.5V	COP888CS
MHW-888CS40DWPC	40 DIP	2.5V-6.0V	COP888CS
MHW-888CS44D5PC	44 PLCC	4.5V-5.5V	COP888CS
MHW-888CS44DWPC	44 PLCC	2.5V-6.0V	COP888CS

MACRO CROSS ASSEMBLER

National Semiconductor offers a COP8 macro cross assembler. It runs on industry standard compatible PCs and supports all of the full-symbolic debugging features of the MetaLink iceMASTER emulators.

Assembler Ordering Information

Part Number	Description	Manual
MOLE™-COP8-IBM	COP8 Macro Cross Assembler for IBM® PC/XT®, PC/AT® or Compatible	424410527-001

SINGLE CHIP EMULATOR DEVICE

The COP8 family is fully supported by single chip form, fit and function emulators. For more detailed information refer to the emulation device specific data sheets and the form, fit, function emulator selection table below.

PROGRAMMING SUPPORT

Programming of the single chip emulator devices is supported by different sources. National Semiconductor offers a duplicator board which allows the transfer of program code from a standard programmed EPROM to the single chip emulator and vice versa. Data I/O supports COP8 emulator device programming with its uniSite 48 and System 2900 programmers. Further information on Data I/O programmers can be obtained from any Data I/O sales office or the following USA numbers:

Telephone: (206) 881-6444 Fax: (206) 882-1043

Single Chip Emulator Selection Table

Device Number	Clock Option	Package	Description	Emulates
COP888CSMHXL-X	X=1 : Crystal X=3 : R/C	44 LDCC	Multi-Chip Module (MCM), UV Erasable	COP888CS
COP888CSMHDX-X	X=1 : Crystal X=3 : R/C	40 DIP	MCM, UV Erasable	COP888CS
COP884CSMHDX-X	X=1 : Crystal X=3 : R/C	28 DIP	MCM, UV Erasable	COP884CS
COP884CSMHDX-X	X=1 : Crystal X=3 : R/C	28 LCC	MCM (Same Footprint as 28 SO), UV Erasable	COP884CS

Duplicator Board Ordering Information

Part Number	Description	Devices Supported
COP8-PRGM-28D	Duplicator Board for 28 DIP Multi-Chip Module (MCM) and for use with Scrambler Boards	COP884CSMHD
COP8-SCRM-DIP	MCM Scrambler Board for 40 DIP Socket	COP888CSMHD
COP8-SCRM-PCC	MCM Scrambler Board for 44 PLCC/LDCC	COP888CSMHXL
COP8-SCRM-SBX	MCM Scrambler Board for 28 LCC Socket	COP884CSMHDX
COP8-PRGM-DIP	Duplicator Board with COP8-SCRM-DIP Scrambler Board	COP884CSMHD, COP888CSMHD
COP8-PRGM-PCC	Duplicator Board with COP8-SCRM-PCC Scrambler Board	COP888CSMHXL, COP884CSMHD

Development Support (Continued)

DIAL-A-HELPER

Dial-A-Helper is a service provided by the Microcontroller Applications group. The Dial-A-Helper is an Electronic Bulletin Board Information system.

INFORMATION SYSTEM

The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communications to and from the Microcontroller Applications Group and a FILE SECTION which consists of several file areas where valuable application software and utilities could be found. The minimum requirement for accessing the Dial-A-Helper is a Hayes compatible modem.

Voice: (408) 721-5582

Modem: (408) 739-1162

Baud: 300 or 1200 Baud

Set-up: Length: 8-Bit

Parity: None

Stop Bit: 1

Operation: 24 Hrs., 7 Days

If the user has a PC with a communications package then files from the FILE SECTION can be down loaded to disk for later use.

ORDER P/N: MOLE-DIAL-A-HLP

Information System Package contains:
Dial-A-Helper Users Manual
Public Domain Communications Software

FACTORY APPLICATIONS SUPPORT

Dial-A-Helper also provides immediate factor applications support. If a user has questions he can leave messages on our electronic bulletin board, which we will respond to.

Easy Logarithms for COP400

National Semiconductor
COP Brief 2

Logarithms have long been a convenient tool for the simplification of multiplication, division, and root extraction. Many assembly language programmers avoid the use of logarithms because of supposed complexity in their application to binary computers. Logarithms conjure up visions of time consuming iterations during the solution of a long series. The problem is far simpler than imagined and its solution yields, for the applications programmer, the classical benefits of logarithms:

- 1) Multiplication can be performed by a single addition.
- 2) Division can be performed by a single subtraction.
- 3) Raising a number to a power involves a single multiply.
- 4) Extracting a root involves a single divide.

When applied to binary computer operation logarithms yield two further important advantages. First, a broad range of values can be handled without resorting to floating point techniques (other than implied by the characteristic). Second, it is possible to establish the significance of an answer during the body of a calculation, again, without resorting to floating point techniques.

Implementation of base₁₀ logarithms in a binary system is cumbersome and unnecessary since logarithmic functions can be implemented in a number system of any base. The techniques presented here deal only with logarithms to the base₂.

A logarithm consists of two parts: an integer characteristic and a fractional mantissa.

TL/DD/6942-1

	CHARACTERISTIC	MANTISSA
LOG ₂ 3 =	1	0.95
LOG ₂ 4 =	2	0.00
LOG ₂ 8 =	3	0.00
LOG ₂ 10 =	3	0.52

FIGURE 1. The Logarithmic Function and Some Example Values

In *Figure 1* some points on the logarithmic curve are identified and evaluated to the base₂. Notice that the characteristic in each case represents the highest even power of 2 contained in the value of X. This is readily seen when binary notation is used.

X ₁₀	X ₂	Log ₂ X	Log ₂ X Where X =			
2 ⁴	2 ³	2 ²	2 ¹	2 ⁰	Characteristic	Even Power of 2
3	0	0	0	1	1	
4	0	0	1	0	2	010.0000
8	0	1	0	0	3	011.0000
10	0	1	0	1	3	

FIGURE 2. Identification of the Characteristic

In *Figure 2* each point evaluated in *Figure 1* has been repeated using binary notation. An arrow subscript indicates the highest even power of 2 appearing in each value of X. Notice that in X = 3 the highest even power of 2 is 2¹. Thus the characteristic of the log₂ 3 is 1. Where X = 10 the characteristic of the log₂ 10 is 3.

To find the log₂ X is very easy where X is an even power of 2. We simply shift the value of X left until a carry bit emerges from the high order position of the register. This procedure is illustrated in *Figure 3*. This characteristic is found by counting the number of shifts required and subtracting the result from the number of bits in the register. In practice it is easier to be going with the number of bits and count down once prior to each shift.

Counter for Characteristic	Value of X in Binary		
1	0 0 0 0	1 0 0 0	Initial
0	1 1 1	0 0 0 0	First Shift
0	1 1 0	0 0 1 0	Second Shift
0	1 0 1	0 1 0 0	Third Shift
0	1 0 0	1 0 0 0	Fourth Shift
0	0 1 1	0 0 0 0	Fifth Shift
Characteristic	Mantissa		Final
0 1 1 . 0 0 0 0	0 0 0 0		Log ₂ X = 3.00

FIGURE 3. Conversion to Base₂ Logarithm by Base Shift

Examination of the final value obtained in *Figure 3* reveals no bits in the mantissa. The value 3 in the characteristic, however, indicates that a bit did exist in the 2³ position of the original number and would have to be restored in order to reconstruct the original value (antilog).

The log of any even power of 2 can be found in this way:

Decimal	Binary	Log ₂
128	10000000	0111.00000000
64	01000000	0110.00000000
32	00100000	0101.00000000
4	00000100	0010.00000000
2	00000010	0001.00000000
1	00000001	0000.00000000

A simple flow chart, and program, can be devised for generating the values found in the table and, as will be apparent, a straight line approximation for values that are not even powers of 2. The method, as already illustrated in *Figure 3*, involves only shifting a binary number left until the most significant bit moves into the carry position. The characteristic is formed by counting. Since a carry on each successive shift will yield a decreasing power of 2, we must start the characteristic count with the number of bits in the binary value (x) and count down one each shift.

FIGURE 6

The program shown develops the \log_2 of any even power of 2 by shifting and testing as previously described. Examine what happens to a value of X that is not an even power of 2. In Figure 7, the number 25 is converted to a base 2 log.

$$25_{10} = 00011002_2$$

Shift left until carry = 1

Characteristic	Carry	Mantissa	Log ₂
0100	1	100100000100	.10010000

Figure 7. Straight Line Approximation of Base₂ Log

The resulting number when viewed as an integer characteristic and a fractional mantissa is 4.5625_{10} . The fraction 0.5625 is a straight line approximation of the logarithmic curve between the correct values for the base₂ logs of 2⁴ and 2⁵. The accuracy of this approximation is sufficient for many applications. The error can be corrected, as will be seen later in this discussion, but for now let's look at the problem of exponents or the conversion to an antilog.

To reconstruct the original value of X, find the antilog, requires only restoration of the most significant bit and then its alignment with the power of 2 position indicated by the characteristic. In the example, approximation ($\log_2 25 = 0100.1001$) restoration of MSB can be accomplished by shifting the mantissa (only) one position to the right. In the process a one is shifted into the MSB position.

Approximation of Log ₂ X	Restoration of MSB
Char. Mantissa	Char. Mantissa
0100.10010000	0100.11001000

The value of the characteristic is 4 so the mantissa must be shifted to the right until MSB is aligned with the 2⁴ position.

2⁷ 2⁶ 2⁵ 2⁴ 2³ 2² 2¹ 2⁰

The completion of this operation restores the value of X ($X = 25$) and is the procedure used to find an antilog. Figure 8 is a flow chart for finding an antilog using this procedure. This implementation in source code is shown in Figure 9.

FIGURE 9

Using the linear approximation technique just described, some error will result when converting any value of X that is not an even power of 2.

Figure 10 contains a table of correct base 2 logarithms for values of X from 1 through 32 along with the error incurred for each when using linear approximation. Notice that no error results for values of X that are even powers of 2. Also notice that the error incurred for multiples of even powers of 2 of any given value of X is always the same.

Value of X	Error
5	0.12
$2 \times 5 = 10$	0.12
$4 \times 5 = 20$	0.12
3	0.15
$2 \times 3 = 6$	0.15
$4 \times 3 = 12$	0.15
$8 \times 3 = 24$	0.15

FIGURE 10. Error Incurred by Linear Approximation of Base 2 Logs

An error that repeats in this way is easily corrected using a look-up table. The greatest absolute error will occur for the least value of X not an even power of 2, X = 3, is about 8%. A 4 point correction table will eliminate this error but will move the greatest uncompensated error to X = 9 where it

will be about 4%. This process continues until at 16 correction points the maximum error for the absolute value of the logarithm is less than 1 percent. This can be reduced to 0.3 percent by distributing the error. Interpolated error values are listed in *Figure 10* and are repeated in *Figure 11* as a binary table.

High Order 4 Mantissa Bits	Binary Correction Value	Hexadecimal Correction Value
0000	0000 0000	0 0
0001	0000 1001	0 9
0010	0000 1101	0 3

1110	0000 0110	0 6
1111	0000 0010	0 2

FIGURE 11. Correction Table for
 L_2 X Linear Approximations

Notice in *Figure 10* that left justification of the mantissa causes its high order four bits to form a binary sequence that always corresponds to the proper correction value. This works to advantage when combined with the COP400 LQID instruction. LQID implements a table look-up function using the contents of a memory location as the address pointer. Thus we can perform the required table look-up without disturbing the mantissa.

Figure 12 is the flow chart for correction of a logarithm found by linear approximation. *Figure 13* is its implementation in COP400 assembly language. Notice that there are two entry points into the program. One is for correction of logs (LADJ:), the other is for correction of a value prior to its conversion to an antilog (AADJ:).

RAM Keep-Alive

National Semiconductor
COP Brief 6

A COPSM application is a small scale computer system and the design of a power shut-down is not trivial. During the time that power is available, but out of the designed operating range, the system must be prevented from doing anything to harm protected data. This will typically involve some type of external protection of timing circuit.

There is an option on the COP420, 420L, and 410L parts called "RAM Keep-Alive" that provides a separate power supply to the RAM area of the chip via the CKO pin. The application of power to the RAM while the remainder of the chip has been powered down via V_{CC} will keep the RAM "alive".

However, the integrity of data in the RAM is not only a function of power but is also influenced by transient conditions as power is removed and reapplied. During power-on, the Power On Reset (POR) circuit will keep transients from causing changes in the RAM states. The condition of power loss will have some probability of data change if external control is not used.

At some point below the minimum operating voltage certain gates will no longer respond properly while others may still be functional until a much lower voltage. During this transition time any false signal could cause a false write to one or more cells. Another effect could be to turn on multiple address select lines causing data destruction.

Testing the rate of data change is very difficult because it must be done on a statistical basis with many turn/on-turn/off cycles. Two factors have a major bearing on the numbers derived by testing. One is to call any change in a related data block a failure, even though more than one bit in that block may have changed (this latter case may well be due to the "address select mode"). The second factor is that without massive instrumentation it is impossible to examine the data after each power cycle. Indeed, to do so might have caused errors!

By running the power cycle for a period of time and then looking for changes, one could overlook multiple changes thus reducing the error rate. This has been minimized by more frequent checking which indicates that the errors are spread out randomly over time.

With a power supply that drops from 4.5 to 2V in approximately 100 ms, the drop-out rate is 1 in 5k to 6k power cycles. Reducing the voltage fall time will cause an improvement in the number of cycles per drop-out. This will reach a limit condition of a very high number (1 per 1 million?) when the power falls within one instruction cycle (4–10 μs for the 420, 15–40 μs for the "L" parts). Attaining very rapid fall time may cause problems due to the lack of decoupling/bypass capacitance. By inserting an electronic switch between the regulator and V_{CC} of the COP chip one might be able to meet this type of fall time. By implication some type of sensing is required to cause the switching.

The desirable approach is to force the COP reset input to zero before the voltage falls below 4.5V. This provides a drop out rate of approximately 1 in 50k for the "L" parts and 1 in 100k for the 420. By also stopping the clock of the "L" parts they can achieve a drop-out rate similar to the 420. While not perfect, the number of cycles between data error should be considered with respect to the needs of the application.

The external circuitry to control the chip during the power transition has several implementations each one being a function of the application. The simplest hardware is found in a battery powered (automotive) application. The circuit must sense that the switched 12V is falling (e.g., at some value much below 1.7V and still greater than 5V). This can be done by using the unswitched 12V as a reference for a divider to a nominal voltage of 8V. As the switched 12V drops below the reference a detector will turn on a clamp transistor to a series switch, the POR, and/or the clock circuit (Figure 1). It should be noted that this draws current during the absence of the switched 12V circuit.

In non-automotive usage a similar circuit can be used where there is a stable reference voltage available to use with the comparator/clamp. Thus a 3.6V rechargeable Ni-Cad battery could be used as the reference voltage and V_{RAM} if the appropriate divider is used to level shift to this operating range.

In AC line-powered applications, a similar method could be used with the raw DC being sensed for drop. Another method would be to sense that the line had missed 2–3 cycles either by means of a charge pump or peak detection technique. This will provide the signal to turn on the clamp. One must make this faster than the time to discharge the output capacitance of the power supply, thus assuring that the clamp has performed its function before the supply falls below spec value.

In conclusion, to protect the data stored in RAM during power-off cycle, the POR should go low before the V_{CC} power drops below spec and come up after V_{CC} is within spec. The first item must be handled with an external circuit like Figure 1 and the latter by an RC per the data sheet.

1.0 Introduction

A variety of techniques for performing analog to digital conversion are presented. The COP420 microcontroller is used as the control element in all cases. However, any of the COPS family of microcontrollers could be used with only minor changes in some component values to allow for different instruction cycle times.

Indirect analog to digital converters are composed of three basic building blocks:

- D/A Converter
- Comparator
- Control logic

In a software driven system the D/A converter and comparator are present but the control logic is replaced by instruction sequences. There are a variety of software/hardware techniques for implementing A/D converters. They differ primarily in their approach to the included D/A. There are two primary approaches to the digital to analog conversion which can in turn be divided into a number of sub-categories:

- D/A as a function of weight closures
 - R/2R ladder
 - Binary weighted ladder
- D/A as function of time
 - RC exponential charge
 - Linear charge/discharge (dual slope)
 - Pulse width modulation

These techniques should be generally familiar to persons skilled in the electronic art. The objective here is to illustrate the application of these established methods to a low cost system with a COPS microcontroller as the intelligent control element. Circuit configurations are provided as well as the appropriate flow charts and code to implement the function.

Some mathematical and theoretical analysis is presented as an aid to understanding the various techniques and their limits. However, it is not the purpose here to provide a definitive theoretical analysis of the analog to digital conversion process or of the various techniques described.

2.0 Simple Capacitor Charge Time Measurement

2.1 BASIC APPROACH

General

Perhaps the simplest means to perform an analog to digital conversion is to charge a capacitor until the capacitor voltage is equal to the unknown voltage. The capacitor voltage and the unknown are compared by means of a standard analog comparator. The unknown is determined simply by counting, in the microcontroller, the amount of time it takes for the charge on the capacitor to reach a value equal to the unknown voltage. The capacitor voltage is given by the standard capacitor charge equation:

$$V_C = V_0 + [V_1 - V_0][1 - e^{-(t/RC)}]$$

where: V_C = capacitor voltage

V_0 = "discharge voltage" — low level voltage

V_1 = high level voltage

The most obvious problem with this method, from the standpoint of software implementation, is the nonlinearity of the

relationship. This can be circumvented in several ways. First of all, a routine to calculate the exponential can be implemented. This, however, usually requires too much code if the exponential routine is not otherwise required in the program. Alternatively, the range of input voltages can be restricted so that only a portion of the capacitor charge curve — which can be approximated with a linear relationship or with some minor straight time curve fitting — is used. Finally, a look up table can be used which will effectively convert the measured time to the appropriate voltage. The look up table has the advantage that all the math can be built into the table, thereby simplifying matters significantly. If arithmetic routines are going to be used, it is clear that the relationship is simplified if V_0 is 0V because it then drops out the equation.

BASIC CIRCUIT IMPLEMENTATION

The circuit in *Figure 1* is the basic implementation of the capacitor charge method of A/D conversion. The selection of input and output used is arbitrary and is dictated by general system considerations. V_0 is the "0" level of the G output and V_1 is the "1" level of the output. The technique is basically to discharge the capacitor to V_0 (which is ideally ground) and then to apply V_1 and increment an internal counter until the comparator changes state. The flow chart and code for this implementation are shown in *Figure 2*.

ACCURACY CONSIDERATIONS

The levels reached by the microcontroller output constitute one of the more significant problems with this basic imple-

mentation. The levels of V_1 and V_0 are not V_{CC} and ground as would be desired. The level is defined by the load on the output, the value of V_{CC} , and the device itself. Furthermore, these levels are likely to change from device to device and over temperature. To be sure, the output values will be at least those given in the data sheet, but it must be remembered that those values are minimum high voltages and maximum low voltages. Typically, the high value will be greater than the spec minimum and the low value will be lower than the spec maximum. In fact, with a light load the values will be close to V_{CC} and ground. Therefore, in order to obtain any accurate result for a voltage measurement the exact values of V_1 and V_0 need to be measured and somehow stored in the microcontroller. Typical values of these voltages can be measured experimentally and an average could be used for final implementation.

The other problem associated with the levels is that the capacitive load on the output line is substantial and far in excess of the values used when specifying the characteristics of the various COP420 outputs. The significant effect of this is that it will take longer than "normal" for the output to reach its maximum value. In addition, it is likely that there will be dips in the output as it rises to its maximum value since the capacitor will start to draw charging current from the output. All of this will be fast relative to the other system times. Still it will affect the result since the level to which the capacitor is attempting to charge is not being applied uniformly and "instantaneously". It can be viewed as though the voltage V_1 is bouncing before it stabilizes.

TL/DD/6935-55

FIGURE 2A. Typical RC Charge A/D Code

TL/DD/6935-2

FIGURE 2B. Charge Flow Chart

A more general problem is that of the tolerance of RC time constant. The value of the voltage with respect to time is obviously related to the RC value. Therefore, a change in that value will result in a change in the voltage for a given time period t . The graph in *Figure 3* illustrates the effect of a $\pm 10\%$ variation in the RC value upon the voltage measured for a given time t . If one cares to work out the math, it comes out that the error is an exponential relationship in much the same manner as the capacitor voltage itself. The maximum error induced for $\pm 10\%$ RC variation is $\pm 3.9\%$.

Remember also that we are measuring time. Therefore variation in the RC value will have a direct, linear effect on the time required to measure a given voltage. It is also necessary that the time base for the COP420 be accurate. A variation in the accuracy in the operating frequency of the COP420 will have a direct impact on the accuracy of the result.

Given the errors mentioned so far and assuming that no changes are made in the hardware, the accuracy of the technique then is determined by the resolution of the time measurement. This is improved in two ways: increase the RC time constant so that there is a smaller change in capacitor voltage for a given time period or try to minimize the loop time required to increment the counter. Lengthening the RC time constant is easier but the cost is increased conversion time. The minimum time to increment a 5 to 8 bit binary counter and test an input is 13 cycle times. For a 9

to 12 bit binary counter this minimum time is 17 cycle times. Note also that the minimum time to perform the function does not necessarily correspond to the minimum number of code words required to implement the function. At a cycle time of $4 \mu\text{s}$, the 13 cycle times correspond to $52 \mu\text{s}$.

2.2 ACCURACY IMPROVEMENTS

Several options are available if it is desired to improve the accuracy of this method. Three such improvements are shown in *Figure 4*. *Figure 4A* is the smallest change. Here a pullup resistor has been added to the G output line and the G line is run open drain internally, i.e., the internal pullup is removed. This improves the "bounce" problem mentioned earlier. The G line will go to the high state and remain there with this setup. However, the addition of the resistor does little more than eliminate the bounce. The degree of improvement is not great, but it is an easy way to eliminate a minor source of error.

Figure 4B is the next step. A 74C04 is used as a buffer. The 74C04 was chosen because of its symmetric output characteristics. Any CMOS gate with such characteristics could be used. The software can easily be adjusted to provide the proper polarity. The COP420 output drives a CMOS gate which in turn drives the RC network. This change does make significant improvements in accuracy. With a light

FIGURE 3

TL/DD/6935-3

load the CMOS gate will typically swing from ground to V_{CC} and its output level is not as likely to be affected by the capacitor discharge.

Figure 4C is the best approach, but it involves the greatest component cost. Here two G outputs are controlling analog switches. Ground is connected to the RC network to discharge the capacitor, and a positive reference is used to charge the capacitor. This reference can be any suitable voltage source: zener diodes, V_{CC} , etc. The controlling voltage tolerance is now clearly the tolerance of the reference. Precise voltage references are readily obtainable. Figure 4C also shows an analog switch connected directly across the capacitor to speed up the capacitor discharge time. When using this version of the basic scheme, remember to include the 'on' resistance of the analog switch connected to V_{REF} in the RC calculation. Failure to do so will introduce error into the result.

Note that the LM339 is a quad comparator. If these comparators are not otherwise needed in the system, they can be used in much the same manner as the CMOS gate mentioned above. They can be used to buffer the output of the COPS device and to reset the capacitor, or whatever other function is required. This has the advantage of fully utilizing

the components in the system and eliminates the need to add another package to the system.

2.3 CONCLUSIONS

This approach is an inexpensive way to perform an A/D conversion. However, it is not that accurate. With a 10% V_{CC} supply and a 10% tolerance in the RC value and 10% variation in the oscillator frequency the best that can be hoped for is about 25% accuracy. If a 1% reference voltage is used, this accuracy becomes about 15%.

Under laboratory conditions—holding all variables constant and using precise measured values in the calculations—the configuration of Figure 2 yielded 5 bit accuracy over an input range of 0 to 3.5V. Over the same range and under the same conditions, the circuit of Figure 4B yielded 7 to 8 bit accuracy. It must be emphasized that these accuracies were obtained under controlled conditions. All variables were held constant and actual measured values were used in all calculations. It is unlikely that the general situation will yield these accuracies unless adjustments are provided and a calibration procedure is used. This could defeat the low cost objective.

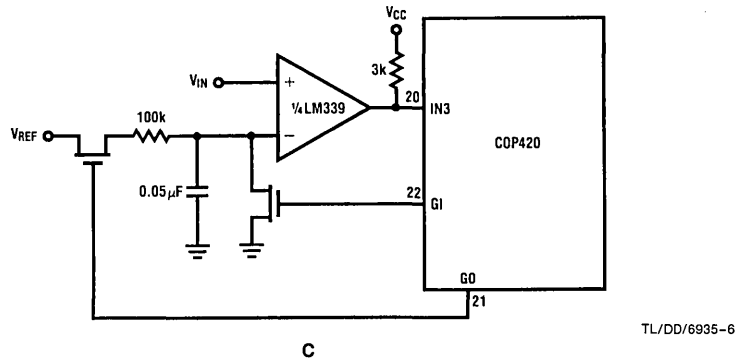

FIGURE 4

3.0 Pulse Width Modulation (Duty Cycle) Technique

3.1 MATHEMATICAL ANALYSIS

The pulse width modulation, or duty cycle, conversion technique is based on the fact that if a repetitive pulse waveform is applied to an RC network, the capacitor will charge to the average voltage of the waveform provided that the RC time constant is sufficiently large relative to the pulse period. See *Figure 5*.

In this technique, the capacitor voltage V_C is compared to the voltage to be measured by means of an analog comparator. The duty cycle is then adjusted to cause V_C to approach the input voltage. The COPS device reads the comparator output and then drives one of its outputs high or low depending on the result, i.e., if V_C is lower than the input voltage, a positive voltage (V_1) is applied to charge the capacitor; if V_C is higher than the input voltage, a lower voltage (V_0) is applied to discharge the capacitor. Thus the capacitor voltage will seek a point where it varies above and below the input voltage by a small amount. *Figure 6* illustrates the capacitor voltage and the comparator output.

Some mathematical analysis here will be useful to help clarify the technique and to point out its restrictions. Referring to *Figure 6*, we have the following:

$$V_A = V_0 + [V_B - V_0][e^{-(t_1/RC)}]$$

$$V_B = V_A + [V_1 - V_A][1 - e^{-(t_2/RC)}]$$

$$= V_1 + [V_A - V_1][e^{-(t_2/RC)}]$$

TL/DD/6935-7

$$V_C = \frac{(V_1 - V_0) \times T_1}{T_1 + T_2}$$

FIGURE 5

TL/DD/6935-8

Capacitor Voltage

TL/DD/6935-9

Comparator Output

TL/DD/6935-10

FIGURE 6

solving for t_1 and t_2 we have:

$$t_1 = -RC \ln[(V_A - V_0)/(V_B - V_0)]$$

$$t_2 = -RC \ln[(V_B - V_1)/(V_A - V_1)]$$

let:

$$V_A = V_{IN} - d_1$$

$$V_B = V_{IN} - d_2$$

substituting the above, the equations for t_1 and t_2 become:

$$t_1 = -RC \ln\left\{\frac{[1 - (d_1/(V_{IN} - V_0))]/[1 + d_2/(V_{IN} - V_0)]}{[1 - d_1/(V_{IN} - V_1)]}\right\}$$

$$t_2 = -RC \ln\left\{\frac{[1 - (d_2/(V_{IN} - V_1))]/[1 - d_1/(V_{IN} - V_1)]}{[1 - d_1/(V_{IN} - V_1)]}\right\}$$

the equations reduce by means of the following assumptions:

1. $d_1 = d_2 = d$
2. $|V_{IN} - V_0| \gg d$
 $|V_{IN} - V_1| \gg d$

applying these assumptions, we get the following:

$$t_1 = -RC \ln[(1 + x)/(1 - x)] \text{ where } x = -d/(V_{IN} - V_0)$$

$$t_2 = -RC \ln[(1 + x)/(1 - y)] \text{ where } y = d/(V_{IN} - V_1)$$

because of the assumptions above, the x and y terms in the preceding equations are less than 1, therefore the following expansion can be used:

$$\ln[(1 + z)/(1 - z)] = 2[z + (z^3)/3 + (z^5)/5 + \dots]$$

substituting we have:

$$t1 = -2RC[x + (x**3)/3 + \dots]$$

$$t2 = -2RC[y + (y**3)/3 + \dots]$$

under assumption 2 above, the linear term completely swamps the exponential terms yielding the following result (after substituting back into the equation):

$$t1 = 2dRC/V_{IN} - V0 \quad t2 = -2dRC/(V_{IN} - V1)$$

therefore:

$$t1/(t1 + t2) = (V1 - V_{IN})/(V1 - V0)$$

$$t2/(t1 + t2) = (V_{IN} - V0)/(V1 - V0)$$

solving for V_{IN} :

$$V_{IN} = [t2/(t1 + t2)][V1 - V0] + V0$$

$$\text{or } V_{IN} = V1 - [t1/(t1 + t2)][V1 - V0]$$

It follows from the above results that by measuring the times $t1$ and $t2$, the input voltage can be accurately determined. As will be seen the restrictions based upon the assumptions above do not cause any serious difficulty.

General Accuracy Considerations

In the preceding calculations it was assumed that the differential output above and below the input voltage was the same. If the comparator output is checked at absolutely regular intervals, and if the intervals are kept as small as possible this assumption can be fairly easily guaranteed—at least to within the comparator offset which is only a few millivolts. As we shall see, this aspect of the technique presents few, if any, difficulties. In addition, there is an RC network at the input of the comparator. The time constant of this network must be long relative to the time between checks of the comparator output. This will insure that the capacitor voltage does not change very much between checks and thereby help to insure that the differences above and below the input voltage are the same.

The next major approximation has to do with the difference between the input voltage and either $V1$ or $V0$. We have relied on this difference being much greater than the amount the capacitor voltage changes above and below the input voltage. This approximation allows the nonlinear terms in the logarithmic expansion to be discarded. In practicality, the approximation means that the input voltage must not be "close" to either $V1$ or $V0$. Therefore, it becomes necessary to determine how closely the input voltage can approach $V1$ or $V0$. It is obvious that the smaller the difference d can be made, the closer the input voltage can approach either reference. The following calculations illustrate the method for determining that difference d . Note, using either $V1$ or $V0$ produces the same result. Thus $V = V1 = V0$.

For at least 1% accuracy

$$x + (x**3)/3 < 0.01x$$

$$\text{therefore } x < 0.173$$

$$\text{since } x = d/(V_{IN} - V) \text{ we have } d < 0.173(V_{IN} - V).$$

Using the same analysis for 0.1% accuracy in the approximation we get $d < 0.0548(V_{IN} - V)$. By applying this relationship, the RC time constant can be adjusted so that, within the time interval, the capacitor voltage does not change by more than d V. The user may then select, within

reason, how close to the references he can allow the input voltage to go.

The next consideration is really just one of simplification. It is clear that if $V0$ is zero, it drops out of the first equation and the relationship is simplified. Therefore, it is desirable to use zero volts as the $V0$ value. The equation then becomes:

$$V_{IN} = V1t2/(t1 + t2).$$

It is obvious by now that the heart of the technique lies in accurately measuring the times $t1$ and $t2$. Clearly this requires that the time base of the COP420 be accurate. Short term variations in the COP420 time base will clearly impact the accuracy of the result. In addition to that there is a serious problem in being able to check the comparator output often enough to get any accuracy and resolution out of simply measuring the times $t1$ and $t2$. This problem is circumvented by measuring many periods of the waveform. Doing this gives a large average, which improves the accuracy and tends to eliminate any spurious changes. Of course, the trade off is increased time to do the conversion. However if the time is available, the technique becomes restricted only by the accuracy of the external components. Those of the comparator and the reference voltage are most critical.

It is clear from the equation above that the accuracy of the result is directly dependent upon the accuracy of the reference voltage $V1$. In other words, it is not possible to be more accurate than the reference voltage. If, however, all that is required is a ratio between the input voltage and the reference voltage, the accuracy of the reference will not be a controlling factor provided that the input voltage tracks the reference. This requires that the input voltage be generated from the reference voltage in some form, e.g., a voltage divider with V_{IN} coming off a variable resistance.

Finally, we have noted that the difference d must be small. If the capacitor had to charge or discharge a long way toward V_{IN} , the nonlinearity of the capacitor charge curve would be significant. This therefore requires that the conversion begin with the capacitor voltage close to the input voltage.

Note that the RC value is not part of the equation. Therefore the accuracy of the time constant has no effect on the result as long as the time constant is long relative to the time between checks of the comparator output.

The final point is that the reference voltages, whatever they may be, must be hard sources. Should these voltages vary or drift at all, they will directly affect the result. In those configurations where the references are being switched in and out, the voltage should not change when it is switched into the circuit.

3.2 BASIC IMPLEMENTATION

General

The objective, then, is to measure the times $t1$ and $t2$. This is accomplished in the software by means of two counters. One of the two counters counts the $t2$ time; the other counter counts the total time $t1 + t2$.

It is necessary to check the comparator output at regular intervals. Thus the software must insure that path lengths

through the test and increment loops are equal in time. Further it is desirable to keep the time required to increment the counters as short as possible. A trade off usually comes into play here. The shortest loop in terms of code required to implement the function is rarely the shortest loop in terms of time required to execute the function. The user has to decide which implementation is best for him. The choice will frequently be governed by factors other than the A/D conversion limits.

It must be remembered that we are now dealing with analog signals. If significant accuracy is required, we are handling very small analog signals. This requires the user to take precautions that are normally required when working with linear circuits, e.g., power supply decoupling and bypassing, lead length restrictions, crosstalk, op amp and comparator stabilization and compensation, desired and undesired feedback, etc. As greater accuracy is sought these factors are more and more significant. It is suggested that the reader refer to the National Semiconductor Linear Applications Handbook and to the data sheets for the various components involved to see what specific precautions should be taken both in general and for a specific device.

The Base Circuit

Figure 7 shows the diagram for the basic circuit required to implement the duty cycle conversion scheme. The flow chart and code required to implement the function are shown in Figure 8. Note that the flow chart and code do not change—except for possible polarity change on output to allow for an inverting buffer—for any of the improvements in accuracy discussed later. The only exception to this is the technique illustrated in Figure 10 and the variations there are minor.

The code and flow chart in Figure 8 implement the technique as described above. The large averaging technique is

used as it would be too difficult to measure the times t_1 and t_2 in a single period. The total time, $t_1 + t_2$, is the viewing window under complete control of the software. This window is a time equal to the total number of counts, determined by desired accuracy, multiplied by the loop time for a single count. A second counter is counting the t_2 time. Special care is taken to insure that all paths through the code take the same length of time since the integrity of the time count is the essence of the technique. The full conversion scheme would use the subroutine in Figure 8. Normally the subroutine would be called first just to get the capacitor charged close to the input voltage. The result obtained here would be discarded. Then the routine would be called a second time and the result used as required.

In the configuration in Figure 7, there is an RC network in both input legs of the comparator. This is to balance the inputs of the device. For this reason, $R_1 = R_2$. C_1 is the capacitor whose voltage is being varied by the pulse waveform. C_2 is in the circuit only for stabilization and symmetry and is not significant in the result. The comparator tends to oscillate when the + and - inputs are nearly equal without capacitor C_2 in the circuit.

As would be expected, the basic circuit has some difficulties. By far the most serious of these difficulties is the output level of the G line. To be sure of the high and low level of this output the levels should be measured. The "1" level will be between the spec minimum of 2.4V and V_{CC} (here assumed to be 5V). The "0" level will be between the 0.4V spec maximum and ground. With light loads, these levels are likely to vary from device to device. Furthermore, we have the same "1" level problem that was mentioned in the simplest technique: the capacitive load is large and the capacitor is charging while the output is trying to go to the high level.

FIGURE 7. Basic Duty Cycle A/D

TL/DD/6935-11

There is also a problem with the low level. When the output goes low, the capacitor begins to discharge through the output device of the COP420. This discharge current has the effect of raising the "0" level and thereby introducing error. Note that we are not talking about large changes in the voltages, especially the low level. Typically, the change will only be a few millivolts but that can translate into a loss of accuracy of several bits.

Under laboratory conditions—holding all variables constant and using precise measured values in the calculations—the circuit of *Figure 7* yielded 5 bit \pm 1 bit accuracy over

the range of V_0 (here measured to be 0.028V) to 3.5V (the maximum specified input voltage for the comparator with $V_S = 5V$). Increasing the number of total counts had very little effect on the result. In the general case, the basic scheme should not be relied upon for more than 4 bits of accuracy, especially if one assumes that $V_1 = V_{CC}$ and $V_0 = 0$. As shall be seen, it is not difficult to improve this accuracy considerably.

3.3 ACCURACY IMPROVEMENTS

General Improvements

Figure 9 illustrates circuit changes that will make significant improvements in the accuracy of the technique. In Figure 9A a CMOS buffer is used to drive the RC network. The output of the COP420 drives the CMOS gate, which here is a 74C04 because of its output characteristics. The main thing that this technique does is to reduce the difficulties with the output levels. Typically, V0 is 0V and V1 is VCC. We also have a "harder" source for the voltages — the levels don't change while the capacitor is charging or discharging. Now, even more clearly than before, the accuracy of VCC is the controlling voltage tolerance. The accuracy of the result will be no better than the accuracy of VCC (for a system requiring absolute accuracy).

Under laboratory conditions, the circuit of Figure 9A yielded the accuracies as indicated below for various total counts. The accuracy increased with the total count until the count exceeded 2048. There was no significant increase in accuracy with this circuit for counts in excess of 2048. (Remember that these results were obtained under controlled conditions). We may then view the results obtained with 2048 counts as the upper limit of accuracy with the circuits of Figure 9A. The results were as follows:

Total Count	Resultant Accuracy
512	8 ± 1/2 bits
1024	9 ± 1bits
2048	9 ± 1/2 bits
4096	9 ± 1/2 bits

FIGURE 9. Improvements to Duty Cycle A/D

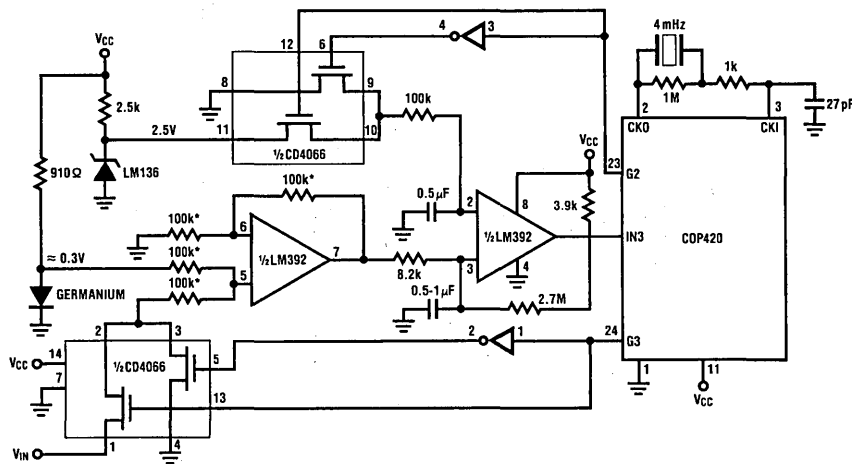

The circuit of *Figure 9B* makes a significant change to improve accuracy. Now the COP420 is controlling analog switches and switching in positive and negative references. Therefore the accuracy of the reference voltages is the controlling factor. Generally this will improve the accuracy over that obtained with *Figure 9A*. With the circuit of *Figure 9B*, with $V_0 = 1V$ (negative reference), and $V_1 = 3V$ (positive reference), 9 bit accuracy was achieved with a total count of 1024. V_0 and V_1 were arbitrarily chosen to place the input voltage approximately in the center of the allowable comparator input range with $V_S = 5V$. Remember, the accuracy of the references is controlling. The result can be no more accurate than the references. Furthermore, these references must be hard sources; i.e., they must not change when they are switched into the circuit as that contributes error into the result.

In *Figure 9C*, capacitive feedback was added to the comparator circuit and the series resistance to V_{IN} was decreased. The feedback added hysteresis and forced the comparator to slew at its maximum rate (significant errors are introduced if the comparator does not change state in a time shorter than the cycle time of the controller). Both of these changes resulted in increased accuracy of the result. With $V_0 = 0$, $V_1 = 5V$ (V_{CC}) and V_{CC} held steady at 5.000V, an accuracy of 10 bits ± 1 bit was achieved over the input range of 0 to 3.5V.

It is obviously possible to use any combination of the configurations in *Figure 9* for a given application. What is used will depend on the user and his specific requirements.

Figure 10 illustrates a further refinement of the basic approach. This configuration can be used if greater accuracies are needed. The major change is the addition of a summing amplifier to the circuit for the purpose of adding a fixed offset voltage to the input voltage. This has the effect of moving the input voltage away from the negative reference (which is 0V here). This offset voltage should be stable as the changes in it will directly affect the result. The offset voltage should be chosen so as to place the effective input voltage (the voltage at the comparator input) approximately in the center of the range between the two references. The precise value of the offset is not critical nor is its source. The forward voltage drop across a germanium diode is used as the offset in *Figure 10*, but this offset can be generated in any convenient manner. The forward voltage drop of the germanium diode is approximately 0.3V. Given this and the negative reference of 0V and a positive reference of 2.5V, the input voltage is restricted to a range of 0 to 2V. Therefore, the effective input voltage (at the comparator input) is approximately 0.3V to 2.3V — well within the limits of the two references. The circuit also includes provision for an autozero self calibration procedure.

Note that the resistors in the summing amplifier should be matched. The absolute accuracy of these resistors is not significant, but their accuracy relative to one another can have a significant bearing on the result. The restriction is imposed so that the output of the summing amplifier is exactly the sum of the input voltage and the offset voltage. This requires unity gain through the amplifier and that the

*Resistors should be matched

$V_{CC} = +5V$
 $0 \leq V_{IN} \leq 2V$

FIGURE 10. Improved Duty Cycle A/D with Autozero

TL/DD/6935-16

impedance in each summing leg be the same. These effects can become very serious if one is trying for significant accuracy—e.g., if 12 bit accuracy is being sought 1% matching of those resistors can introduce an error of 1% maximum. While 1% accurate is fairly good, it is significantly less than 12 bit accuracy. Related to this effect is a possible problem with the source impedance of the input voltage. If that impedance is significant in terms of its ratio to the summing resistor, errors are introduced just as if the resistors are mismatched. "Significant" is determined in terms of the desired system accuracy and the relative impedance values. The comparator section is using some feedback to provide hysteresis for stability and a low series resistance is used for the input to the comparator.

Most significantly, this configuration allows a true zeroing of the system. Through the additional analog switches shown, the COP420 can easily perform an autozero function by

tying the input to ground and measuring the result. Thus the system offsets can be calculated, stored and subtracted from the result. This improves the accuracy and is also more forgiving on the choice of the comparator and op amp selected. Furthermore, the offset can be periodically recomputed by the COP420 thereby compensating for drift in system offsets. Nonetheless, the accuracy of the reference is the controlling factor. It is NOT possible to obtain an absolute (as opposed to ratiometric) accuracy of 12 bits without a reference that is accurate to 12 bits. The LM136 used in *Figure 10* is a 1% reference. Although not inherently accurate to 12 bits, the voltage of the LM136 may be trimmed to exact value by means of a variable resistor. The data sheet of the LM136 illustrates this connection. Under laboratory conditions, the circuit of *Figure 1* yielded 11 bit ± 1 bit accuracy with a total count of 4096 over the input range of 0 to 2V. *Figure 11* indicates the flow chart and the code required to implement the technique of *Figure 10*.

4.0 Dual Slope Integration Techniques

4.1 Mathematical Background

(Some of this background information is taken from National Semiconductor Linear Applications Note AN-155. The reader is referred to that document for other related general information.)

The basic approach of dual slope integration conversion techniques is to integrate a voltage across a capacitor for a fixed time, and then to integrate in the other direction with a known voltage until the starting point is reached. The ratio of the two times then represents the unknown voltage. Some of the math below in conjunction with Figure 12 will illustrate the approach.

TL/DD/6935-18

TL/DD/6935-19

FIGURE 12. Dual Slope Integration—Basic Concept

$$I_X = C \frac{dV}{dt} = V_X/R$$

$$V_X = RC \frac{dV}{dt}$$

$$\int_0^{T_1} V_X dt = \int_0^V RC dV$$

$$V_X T_1 = RC V$$

$$V = V_X T_1 / RC = I_X T_1 / C$$

Similarly:

$$I_{REF} = C \frac{dV}{dt} = V_{REF}/R$$

$$V_{REF} = RC \frac{dV}{dt}$$

$$\int_{T_1}^{T_1 + T_X} V_{REF} dt = \int_V^0 RC dV$$

$$V_{REF} T_X = -RC V$$

$$V = -V_{REF} T_X / RC$$

$$-V_{REF} T_X / RC = V_X T_1 / RC$$

$$V_X = -V_{REF} T_X / T_1$$

Two important facts arise from the preceding mathematics. First of all, there is a linear relationship involved in determining the unknown voltage. Secondly, the negative sign in the final equation indicates that the reference and the unknown, relative to some point (which may be 0V or some bias voltage), have opposite polarity. Thus, if it is desired to measure 0 to +5V, the reference voltage must be -5V. If the input is restricted to 2.5 to 5V, the reference can be 0V as the integrator and comparator are biased at +2.5V (then the 0V is in fact -2.5V relative to the biasing voltage, and the input range is 0 to 2.5V relative to the same bias voltage).

There are some difficulties with dual polarity conversion using the dual slope method. It is clear from the math above that if the input voltage will be dual polarity, it is necessary to have two references—one of each polarity. The midrange biasing arrangement briefly described above eliminates

the need for two different polarities but does not help very much since two references are still required—one at the positive value and one at the bias value. Ground is the other reference. Further, the need to select one of two references further complicates the circuitry involved to implement the approach. Also, the dual requirement brings up a difficulty with the bias currents of the integrator and comparator. They could add to the slope in one polarity and subtract in the other.

The only real operational difficulty in dual slope systems is establishing the initial conditions on the integrating capacitor. If this capacitor is not at the proper initial conditions, accuracy will be severely impaired. Figure 12 indicates a switch across the capacitor as a means of initializing it. In a software driven system, the initialization can be accomplished by doing two successive conversions. The result of the first conversion is discarded. It is performed only to initialize the capacitor. The second conversion produces the valid result. One need only insure that there is not significant time lapse between the two conversions. They should take place immediately after one another.

This approach obviously lengthens conversion time but it eliminates many problems. The alternative to this approach of two successive conversions is to take a great deal of care in insuring the initial state of the integrating capacitor and in selecting op amps and comparators with low offsets.

4.2 THE BASIC DUAL SLOPE TECHNIQUE

Figure 13 indicates an implementation of the basic dual slope technique. This is a single polarity system and thus requires only the single reference voltage. The circuit of Figure 13 is perhaps not the cheapest way to implement such a scheme but it is representative and illustrates the factors that must be considered.

Consider first the means of initializing the integrating capacitor C1. The routine here connects the input to ground and does a conversion on zero volts as a means of initialization. Subsequently—and this is typical of the more usual technique—two conversions are performed. The first conversion is to initialize the capacitor. The second conversion yields the result. Some form of initialization or calibration procedure is required to achieve optimum accuracy from dual slope conversion schemes.

The comparator in this circuit is used in the inverting mode and has positive feedback as recommended in the LM111 data sheet. The voltage reference is the LH0070, which is a 0.01% reference. A resistive voltage divider on the LH0070 creates the 5V value. The use of the voltage divider brings up two difficulties (which can be overcome if the LH0070 is used at its full value, thus eliminating the divider, and the result properly scaled in the microcontroller or series integrating resistor increased). First, the impedance of the reference must be small relative to the series resistance used in the integrator. If this were not the case, the slopes would

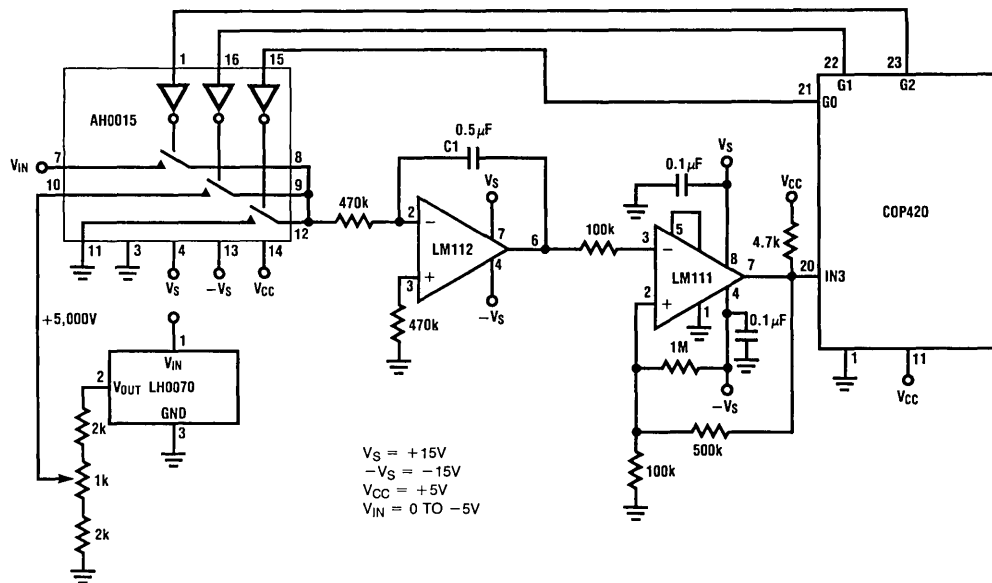

FIGURE 13. Basic Dual Slope Integration A/D Scheme

TL/DD/6935-20

show an effect due to the difference in the R value between the applied reference voltage and the unknown input. (By the same token, the output impedance of the source supplying the unknown must also be small relative to that series integrating resistor). Secondly, the bias currents of the integrator may be such as to affect the reference voltage when it is coming from a simple resistor divider. Both problems are reduced if small resistor values are used in the divider. Note also that current mode switching would reduce the problem as well. It should be pointed out that the errors introduced by these problems are not gross deviations from the expected value. They are small errors that will not make much difference in the majority of applications. They are, however the kind of errors that can make the difference between a system accurate to 10 bits and one accurate to 12 bits (assuming all other factors are the same).

Figure 14 shows the flow chart and code required to implement the basic dual slope technique as shown in Figure 13. Under laboratory conditions an accuracy of 12 bits ± 1 bit was achieved. The method is slow, with the maximum conversion time equal to $2 \times T_{REF}$. Notice that the accuracy of V_{CC} and that of the integrating resistor and capacitor are not involved in the accuracy of the result. The accuracy of V_{REF} is, of course, controlling if absolute accuracy—rather than ratiometric accuracy—is desired. The absolute accuracy of the circuit can be no better than the accuracy of the reference. If ratiometric accuracy is all that is required, there is no particular problem. The accuracy is merely relative to the reference. The R and C values do not impact the accuracy because the integration in both directions is being done through the same R and C. Results would be quite different if a different value of R or C was used for one of the slopes.

4.3 MODIFIED DUAL SLOPE TECHNIQUE

General

The basic idea of the modified dual slope technique is the same as that of the basic approach. The modified approach eliminates the need for dual polarity references and is also more forgiving in the selection of the op amp and comparator required. Figure 15 illustrates the basic idea.

TL/DD/6935-22

TL/DD/6935-23

FIGURE 15. Modified Dual Slope — Basic Concept

The math analysis is much the same:

$$I_X = C \frac{dV}{dt} = (V_X - V_{MAX})/R$$

$$V_X - V_{MAX} = RC \frac{dV}{dt}$$

$$(V_X - V_{MAX})T_1 = RC$$

$$V = (V_X - V_{MAX})T_1/RC$$

Similarly:

$$I_{REF} = C \frac{dV}{dt} = (V_{REF} - V_{MAX})/R$$

$$(V_{REF} - V_{MAX})T_X = -VRC$$

$$V = -(V_{REF} - V_{MAX})T_X/RC$$

$$(V_{MAX} - V_{REF})T_X = (V_X - V_{MAX})T_1$$

$$V_X = V_{MAX} + (V_{MAX} - V_{REF})T_X/T_1$$

The main difference between this and the basic approach is the offset voltage V_{MAX} . The main restriction is that all input voltage values (V_X) are less than V_{MAX} . It is also apparent that the total count is proportional to the difference between V_{MAX} and V_X . The only significant effect of this is, however, to slightly complicate the arithmetic required to arrive at a value for V_X .

Given that the input voltage V_X is always less than V_{MAX} , the modified dual slope technique is automatic polarity. This fact comes straight out of the equation above. Thus dual polarity references are not required. However, two precise voltages are required: V_{MAX} and V_{REF} . However, the V_{MAX} value can be used for a zero adjust as indicated in Figure 16. This means that the V_{MAX} value need not be so precise as it will be adjusted in a calibration procedure to produce a zero output. This adjustment amounts to a compensation for the bias currents and offsets. Thus the COP420 can use the supposed value of V_{MAX} with V_{MAX} later being "tweaked" to give the proper result at zero input. In addition, the initialization loop for the integrating capacitor includes the comparator. Thus the initial condition on the capacitor becomes

not zero but the sum of the offset voltages of the comparator and op amp. Thus the choice of these components is not critical in a modified dual slope approach.

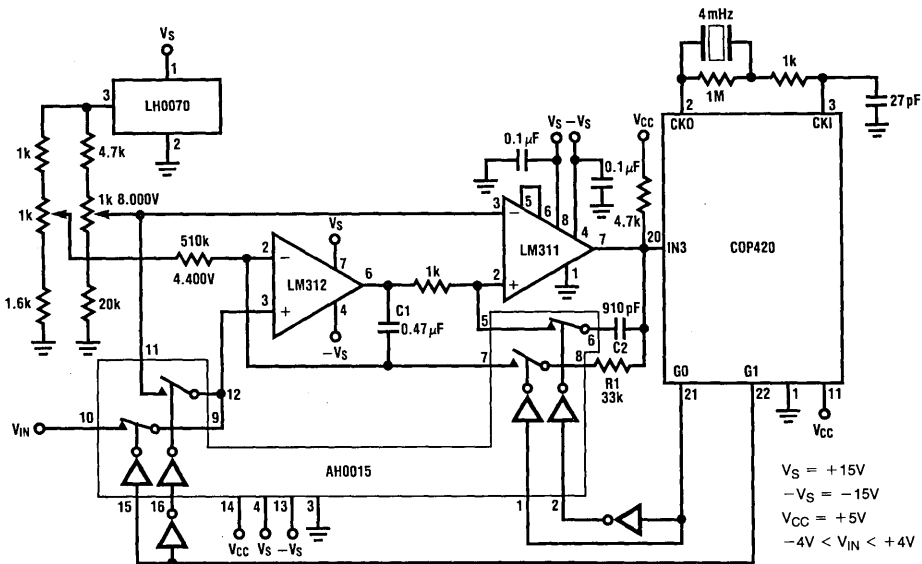

An Example of the Modified Dual Slope Approach

Figure 16 illustrates an implementation of the modified dual slope technique. The system is calibrated by holding V_{IN} to ground and then adjusting V_{MAX} for a "0" result. Capacitor C1 is the integrating capacitor. Capacitor C2 is used only to cause a rapid transition on the comparator output. C2 is especially useful if an op amp is being used as the comparator stage. Resistor R1 is just part of the capacitor initializing loop. An LH0070 is being used to generate the reference voltage and the V_{MAX} value. The discussion previously about these being hard sources is equally relevant here. In fact, this problem was much more significant in this particular implementation and made the difference between a 10 and 12 bit system. As shown, the technique was accurate to 10 bits. Another bit was obtained when the V_{MAX} and V_{REF} values were buffered. It must be remembered that when trying to achieve accuracies of this magnitude board layout, parts placement, lead length, etc. become significant factors that must be specifically addressed by the user.

There are some other considerations in using this technique. The amount of time required to count the specified number of counts starts to become a significant factor. If it takes "too long" to do the counting, the capacitor can charge to either supply voltage depending on which direc-

tion it is integrating. This causes the wave shape shown in Figure 15 to flatten out. This effectively limits the input range for all accuracy is lost once that waveform flattens out. In fact, this was the limiting factor on the accuracy in Figure 16 as shown. Given the amount of time required for an increment of the counter for T_{REF} (or T_X), it was not possible to reach the 4096 counts required for 12 bit accuracy before the waveform flattened out. Decreasing the total count solves the problem at the expense of accuracy. It is therefore desirable to keep the loop time required for an increment as fast as possible. The code to implement Figure 16 is shown in Figure 17 and reflects that concern. The other way to solve the problem is to use a large value for R and C. This is the easiest solution and preserves accuracy. Its cost is increased conversion time.

Both the basic and modified dual slope schemes can be very accurate and are commonly used. They tend to be relatively slow. In many applications, however, speed is not a factor and these approaches can serve very well. There are various approaches to dual slope analog to digital conversion which try to improve speed and/or accuracy. These are usually multiple ramping schemes of one form or another. The heart of the approach is the basic scheme described above. It is not the purpose here to delve into all the possible ways that dual slope conversion may be accomplished. The control software is not significantly different regardless of which particular variation is used. The basic ramping control is the same as that indicated here.

TL/DD/6935-24

FIGURE 16. Modified Dual Slope Integration

The number of components required to implement a dual slope scheme is not related to the desired accuracy. The approach is generally tolerant as to the op amps and comparators used as long as proper care is given to the initialization of the integrating capacitor.

Precise references are not required if a ratiometric system is all that is required. Cheaper switches can be safely used. The dual slope scheme controlled by a COPS microcontroller can be a very cost effective solution to an analog to digital conversion problem.

5.0 Voltage to Frequency Converters, VCO's

5.1 BASIC APPROACH

The basic idea of this scheme is simply to use the COP420 to measure the frequency output of a voltage to frequency converter or VCO. This frequency is in direct relation to the input voltage by the very nature of such devices. There are really only two limiting factors involved. First of all, the maximum frequency that can be measured is defined in the microcontroller by the amount of time required to test an input and increment a counter of the proper length. With the COP420 this upper limit is typically 10 to 15 kHz. The other limiting factor is simply the accuracy of the voltage to frequency converter or VCO. This accuracy will obviously affect the accuracy of the result.

Two basic implementations are possible and their code implementation is not significantly different. First, the number of pulses that occur within a given time period may be counted. This is straightforward and fairly simple to implement. The crucial factor is how long that given time period should be. To get the maximum accuracy from this implementation the time period should be one second. Such a time period would allow the distinction between the frequencies of 5000 Hz and 5001 Hz for example (assuming the V to F converter was that accurate or precise). Decreasing the amount of time will decrease the precision of the result. The alternate approach is to measure (by means of a counter) the amount of time between two successive pulses. This period measurement is only slightly more complicated than the pulse counting approach. The approach also makes it possible to do averaging of the measurement during conversion. This will smooth out any changes and add stability to the result. The time measurement technique is also faster than the pulse counting approach. Its accuracy is governed by how finely the time periods can be measured. The greater the count that can be achieved at the fastest input frequency — shortest period — the more accurate the result.

Figure 18 illustrates the basic concept. Figure 19A shows the flow charts and code implementation for both of the approaches discussed above. Note that whatever type of V to F converter is used, the code illustrated in Figure 19A is not significantly changed. In the code of Figure 19A, the interrupt is being used to test an input and thereby decreases the total time loop.

5.2 THE LM131/LM231/LM331

The LM131 is a standard product voltage to frequency converter with a linear relationship between the input voltage and the resultant frequency. The reader should refer to the data sheet for the LM131 for further information on the device itself and precautions that should be taken when using the device. *Figure 20* is the basic circuit for using the LM131. *Figure 21* represents improvements that increase the accuracy (by increasing the linearity) of the result. Note that these circuits have been taken from the data sheet of the LM131 and the user is referred there for a further discussion of their individual characteristics. With the LM131 the frequency output is given by the relationship:

$$F_{OUT} = (V_{IN}/2.09) (1/R_T C_T) (R_S/RL)$$

It is clear from the expression above that the accuracy of the result depends upon the accuracy of the external com-

ponents. The circuit may be calibrated by means of a variable resistance in the R_S term (a gain adjust) and an offset adjust. The offset adjust is optional but its inclusion in the circuit will allow maximum accuracy to be obtained. The standard calibration procedure is to trim the gain adjust (R_S) until the output frequency is correct near full scale. Then set the input to 0.01 or 0.001 of full scale and trim the offset adjust to get F_{OUT} to be correct at 0.01 or 0.001 of full scale. With that calibration, the circuit of *Figure 20* is accurate to within $\pm 0.03\%$ typical and $\pm 0.14\%$ maximum. The circuit of *Figure 21* attains the spec limit accuracy of $\pm 0.01\%$.

5.3 VOLTAGE CONTROLLED OSCILLATORS (VCO's)

A VCO is simply another form of voltage to frequency converter. It is an oscillator whose oscillation frequency is dependent upon the input voltage. Numerous designs for VCO's exist and the reader should refer to the data sheets and application notes for various op-amps and VCO devices. The code in *Figure 19* is still applicable if a VCO is used. The only possible difficulty that might be encountered is if the relationship between frequency and input voltage is non-linear. This does not affect the basic code but would affect the processing to create the final result. A sample circuit, taken from the data sheet of the LM358, is shown in *Figure 22*. The accuracy of the VCO is the controlling factor.

5.4 A COMBINED APPROACH

Elements of the period measurement and pulse counting techniques can be combined to produce a system with the advantages of both schemes and with few problems. Such a system is only slightly more complicated in terms of its software implementation than the approaches mentioned above. Note that in a microcontroller driven system, no additional hardware beyond the voltage to frequency converter is required to implement this approach. Basically, the microcontroller establishes a viewing window during which time the microcontroller is both measuring time and counting pulses. The result can be very precise if two conditions are met. First, when the microcontroller determines that it needs the conversion information, the microcontroller does not begin counting time or pulses until the first pulse is received from the VFC (first pulse after the microcontroller "ready"). Note, the COPS microcontroller could provide a "start conversion" pulse to enable the VFC if such an arrangement were desirable. The time would be counted for a fixed period and the number of pulses would be counted. After the fixed period of time the controller would wait for the next pulse from the VFC and continue to count time until that pulse is received. The ratio of the total time to the number of pulse is a very precise result provided that all the system times are slow enough that the microcontroller can do its job. The speed limits mentioned previously apply here. It is clear that the total time is not fixed. It is some basic time period plus some variable time. This is a little more complicated than simply using a fixed time, but it allows greater accuracies to be achieved. Also, the approach takes approximately the same amount of time for all conversions. It is also faster than the simple pulse counting scheme.

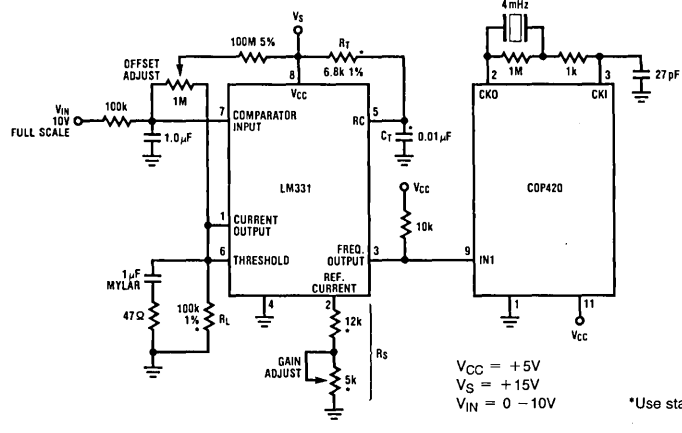

FIGURE 20. Basic LM331 Connection

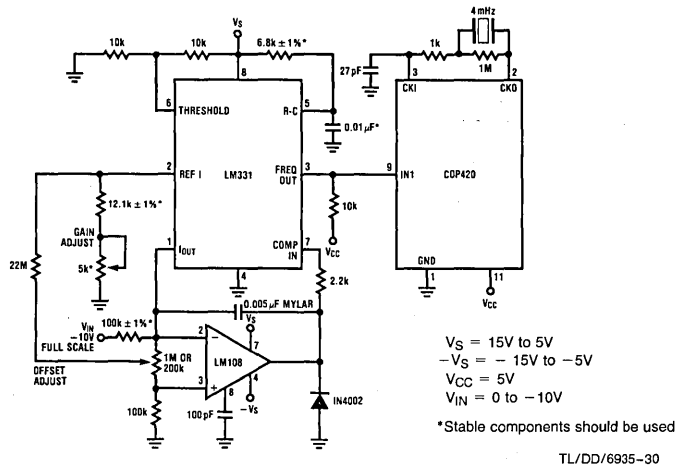

FIGURE 21. A to D with Precision Voltage to Frequency Converter

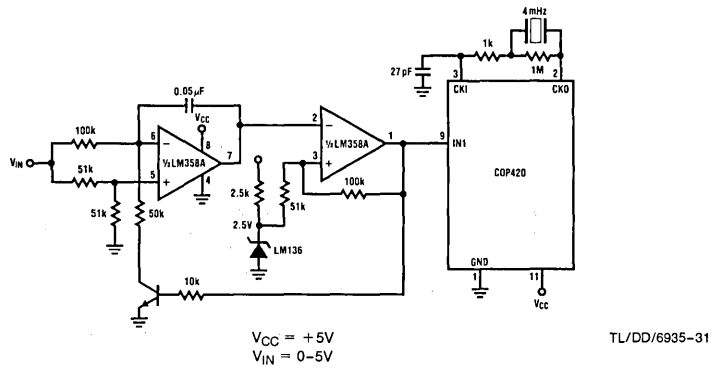

FIGURE 22. A to D with VCO

6.0 Successive Approximation

6.1 BASIC APPROACH

The successive approximation technique is one of the more standard approaches in analog to digital conversion. It requires a counter or register (here provided by the COP420), a digital to analog converter, and a comparator. *Figure 23A/B* illustrates the basic idea with the COP420. In the most basic scheme, the counter is reset to zero and then incremented until the voltage from the digital to analog converter is equal to the input voltage. The equality is determined by means of the comparator. *Figure 24B* illustrates the flow chart and code for this most basic approach. The preferred approach is illustrated in *Figure 25A/B*. This is the standard binary search method. The counter or register is set at the midpoint and the "delta" value set at one half the midpoint. The "delta" value is added or subtracted from the initial guess depending on the output of the comparator. The "delta" value is divided by 2 before the next increment or decrement. The method repeats until the desired resolution is achieved. While this approach is somewhat more complicated than the basic approach it has the advantage of always taking the same amount of time for the conversion

regardless of the value of the input voltage. The conversion time for the basic approach increases with the input voltage. The preferred approach is almost always faster than the basic approach. The basic approach is faster only for those voltages near zero where it has only a few increments to perform.

The accuracy of the approach is governed by the accuracy of the digital to analog converter and the comparator. Thus, the result can be as accurate as one desires depending on the choice of those components. Digital to analog converters of various accuracies are readily available as standard parts. Their cost is usually in direct relation to their accuracy. The reader should refer to the National Semiconductor Data Acquisition Handbook for some possible candidates for digital to analog converters. It is not the purpose here to compare those parts. The COPS interface to these parts is generally straightforward and follows the basic schematics shown in *Figure 23*. The user should take note and make sure the input and output ports of the converter are compatible — in terms of voltages and currents — with the COPS device. This is generally not a problem as most of the parts are TTL compatible on input and output. The precautions and restrictions as to the use of any given device are governed by that device and are indicated in the respective data sheets.

FIGURE 25B. Binary Search Successive Approximation Flow Chart

6.2 SOME COMMENTS ON RESISTOR LADDERS

If the user does not wish to use one of the standard digital to analog converters, he can always build one of his own. One of the most standard methods of doing so is to use a resistor ladder network of some form. *Figure 26* illustrates the basic forms of binary ladders for digital to analog converters. The figures also show the transition from the basic binary weighted ladder in *Figure 26A* to the standard R-2R ladder *Figure 26C*.

Consider *Figure 26A*. The choice of the terminating resistor is made by hypothesizing that the ladder were to go on ad infinitum. It can then be shown that the equivalent resistance at point X in that figure would be equal to $128R$, the same value as the resistor to the least significant bit output. This fact is used to create the intermediate ladder of *Figure 26B*. This step is done because it is usually undesirable to have to find the multitude of resistor values required in the basic binary ladder. Thus, the modification in *Figure 26B* significantly reduces the number of resistor values required. As stated earlier, the resistance looking down the ladder at point X in *Figure 2* is equal to the resistor connected to the binary output at that point; here the value is $2R$. Remembering the objective is to minimize the number of different values required, if we simply use the same R-2R arrangement as before with a termination of $2R$ we get an effective resistance at point Y of *Figure 26B* or $0.5R$. This means that a serial resistance of $1.5R$ is required to maintain the integrity of the ladder. If we carry this on through 8 bits, the circuit of

Figure 26B results. From this it is only a small step to create the standard R-2R network. The analysis is the same as done previously.

There is absolutely no restriction that the ladders must be binary. A ladder for any type of code can be constructed with the same techniques. Ladders comparable to *Figures 26A* and *26B* are shown in *Figure 27* for a standard 8421 BCD code. With the BCD code, the input must be considered in groups of digits with four bits creating one digit. This is the direct analog of 1 binary digit per unit. We need four inputs to create one decimal digit. Thus the resistor values in each decimal digit are 10 times the values in the previous decimal digit just as the resistor value for each successive binary digit was twice the value for the preceding binary digit. Note that this analysis can be easily extended to any code. The termination resistance is calculated in the same manner—assume the decimal digit groupings extend out to infinity. It can be shown that the resistance of the ladder at point X in *Figure 27A* is $480R$. Thus *Figure 27A* represents the basic 8241 BCD ladder for three digit BCD number. This termination resistance will vary with where it is placed. Basically this resistance is equal to nine times (for a decimal ladder) the parallel resistance of the last digit implemented. (This relation can be shown mathematically if one desired, the multiplier is a function of the type of ladder used—multiplier = 1 for binary systems, 9 for decimal systems, etc.) Thus the termination resistance would be $48R$ if the network were terminated after the 2nd digit and $4.8R$ if the network were terminated after the 1st digit implemented. In

FIGURE 26. Binary Ladders

TL/DD/6935-36

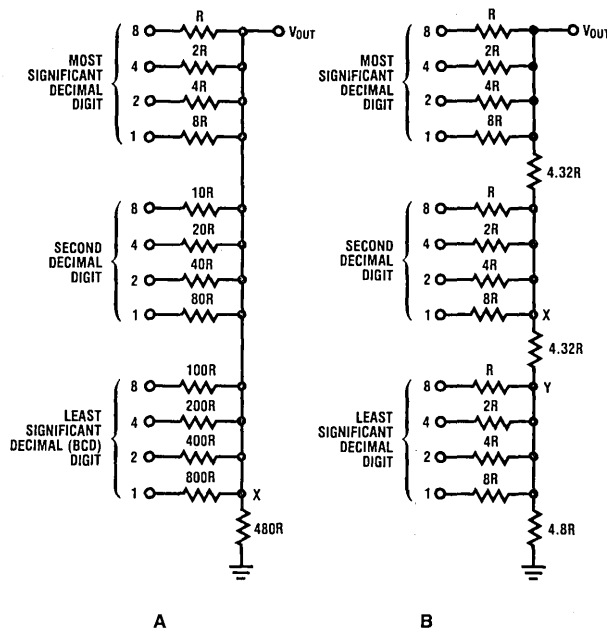

Figure 27B we are attempting to use only the resistor values for one decimal digit. This means that the last terminating resistor must be a $4.8R$ by the analysis above. Thus at point X in Figure 27B we must have an equivalent of resistance of $4.8R$. The equivalent resistance at point Y of Figure 27B, looking down from the ladder, is $0.48R$. Thus the other series resistance must be $4.32R$ ($4.8R - 0.48R$). Thus the network of Figure 27B results.

Generally, ladders can be very effective tools when understood and used properly. They can be significantly more involved than indicated here. There are a number of texts and articles that cover the subject very nicely and the reader is referred to them if more information on ladder design, the use of ladders, and advanced techniques with ladders is desired.

One final note is of some interest. The ladders may be readily constructed for any type of code to create the analog voltage. Note that there is no restriction that the code, or the ladder network, be linear. Thus, effective use of ladder networks may significantly reduce system difficulties and

complexities caused by the fact that the analog to digital conversion is being performed on a voltage source that changes nonlinearly, for example a thermistor temperature probe. By using the properly designed ladder network, the nonlinearity can effectively be eliminated from consideration in the code implementation of the analog to digital conversion.

The accuracy of ladders is a direct function of the accuracy of the resistors and the accuracy of the voltage source inputs. This is obvious since the analog voltage is in fact created by means of equivalent voltage dividers created when the various inputs are on or off. It is also essential that the ladder sources be the precise same value at all inputs to the ladder network. If this is not the case, errors will be introduced. In addition, the output impedance of the voltage source should be as small as possible. The success of the ladder scheme depends on the ratios of the resistance values. Inaccuracies are introduced if those ratios are disturbed. Some possible implementations of the successive approximation approach with a ladder network used for the digital to analog conversion are indicated in Figure 28.

TL/DD/6935-37

FIGURE 27. 8421 BCD Ladders

Note that these are functional diagrams. Feedback or hysteresis for comparator stabilization are not shown. The reader should be aware that his particular application may require that these factors be considered. *Figure 28A* is the simplest scheme and also the least accurate. With little or no load, the high output level of the L buffer should be very close to V_{CC} and the low level close to ground. Also the output impedance of the buffers must be considered. Therefore, rather large resistor values are used—both to keep the load very small and to dwarf the effect of the output imped-

ance. With the configuration in *Figure 28A*, four bit accuracy is about the best that can be achieved. By being extremely careful and using measured values, an additional bit of accuracy may be obtained but care must be used. However, the schematic of *Figure 28A* is very simple. *Figure 28B* represents the next step of improvement. Here we have placed CMOS buffers in the network. This eliminates the output impedance and reduces the level problems of the circuit of *Figure 28A*. The CMOS buffer will swing rail to rail, or nearly so. The accuracy of V_{CC} and the resistor network is then

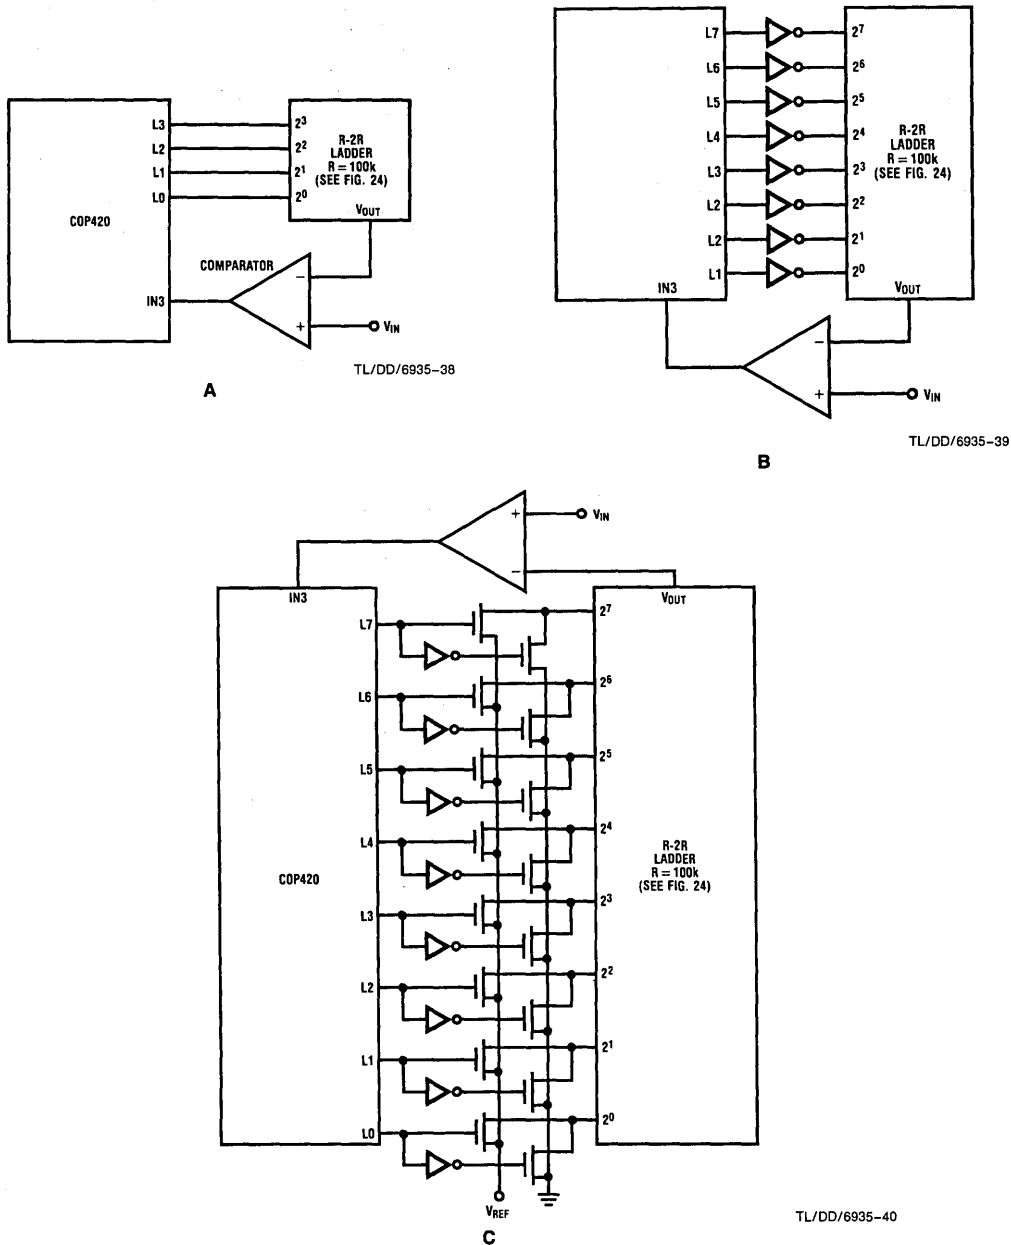

FIGURE 28. Interfaces to Ladder Networks

controlling. Using 1% resistors and holding V_{CC} constant, the user should be able to achieve 7 to 8 bit accuracy without much difficulty. Remember, however, that V_{CC} is one of the controlling factors. If V_{CC} is $\pm 5\%$, there is no point in using 1% resistors since the V_{CC} tolerance swamps their effect. *Figure 28C* is the final and most accurate approach. Naturally enough, it is the most expensive. However, one can get as accurate as one desires. Here, an accurate reference is required. That reference is switched into the network by means of the analog switch. Alternately, ground may be connected to the input. Now the user need only consider the accuracy of the reference and the accuracy of the resistors. However, the on impedance of the switches must be considered. It is necessary to make this on impedance as low as possible so as not to alter the effective resistor values.

7.0 "Offboard" Techniques

7.1 GENERAL COMMENTS

This section is devoted to a few illustrations of interfacing the COP420 to standard, stand alone analog to digital converters. These standard converters are used as peripherals to the COPS device. Whenever the microcontroller requires a new reading of some analog voltage, it simply initiates a read of the peripheral analog to digital converter. As a result, the accuracies and restrictions in using the converters are governed by those devices and not by the COPS device. These techniques are generally applicable to other A to D

converters not mentioned here and the user should not have difficulty in applying these principles to other devices. It should be pointed out that in almost every instance, the choice of COP420 inputs and outputs is arbitrary. Obviously, when there is an 8-bit bus it is natural, and most efficient, to use the L port to interface to the bus. Generally, the G lines have been used as outputs rather than the D lines simply because the G lines are, in many instances, somewhat easier to control. The choice of input line is also free. If the interrupt is not otherwise being used, it may be possible to utilize this feature of IN1 for reading a return signal from the converter. However, this is by no means required. If there is a serial interface it is clearly more efficient to use the serial port of the COP420 as the interface. If a clock is required, SK is the natural choice.

7.2 ADC0800 INTERFACE

The ADC0800 is an 8-bit analog to digital converter with an 8-bit parallel output port with complementary outputs. The ADC0800 requires a clock and a start convert pulse. It generates an end of conversion signal. There is an output enable which turns the outputs on in order to read the 8-bit result.

The reader is referred to the data sheet for the ADC0800 for more information on the device. The circuit of *Figure 29* illustrates the basic implementation of a system with the ADC0800. The interface to the COP420 is straightforward. The appropriate timing restrictions on the control signals are easily met by the microcontroller.

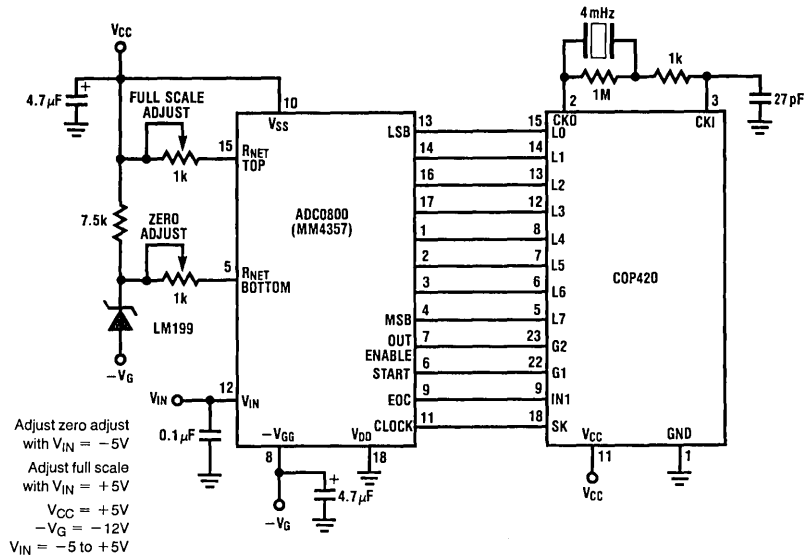

FIGURE 29. Simple A/D with ADC0800

TL/DD/6935-41

Figure 30 is the flow chart and code required to do the interfacing. As can be seen, the overhead in the COP420 device is very small. The choice of inputs and outputs is arbitrary. The only pin that is more or less restricted is the use of SK as the clock for the converter. SK is clearly the output to use for that function as, when properly enabled, it provides pulses at the instruction cycle rate.

7.3 ADC0801/2/3/4 INTERFACE

The ADC0801 family of analog to digital converters is very easy to interface and is generally a very useful offboard con-

verter. The interface is not significantly different from that of the ADC0800, but the ADC0801 family are a much better device. The four control signals are somewhat different, although there are still four control lines. Here we have a chip select, a read, a write, and an interrupt signal. All are negative going signals. Start conversion is the ANDing of chip select and write. Output enable is the ANDing of chip select and read. The interrupt output is an end convert signal of sorts. The device may be clocked externally or an RC may be connected to it and it will generate its own clock for the conversion. In addition the device has differential inputs

8.0 Conclusion

Several analog to digital techniques using the COPS family have been presented. These are by no means the only techniques possible. The user is limited only by his imagination and whatever parts he can find. The COPS family of parts is extremely versatile and can readily be used to perform the analog to digital conversion in almost any method. Generally, those techniques where the COPS device is doing the counting or timekeeping are slow. However, those techniques are generally slow inherently. The fastest methods are those where the conversion is being done offboard and the COPS device is merely reading the result of the conversion when required. Also, an attempt has been made to illustrate the lower cost techniques of analog to digital

conversion. This, by itself, restricts most of the techniques described to about 8-bits accuracy. As was mentioned several times, the greater the accuracy that is desired the more accurate the external circuits must be. Ten and twelve-bit accuracies, and more, require references that are accurate. These get very expensive very rapidly. There is nothing inherent in the COPS devices that prevents them from being used in accurate systems. The precautions are to be taken in the system regardless of the microcontroller. The only problem is that, in those accurate systems where the COPS device is doing the timekeeping and counting, this increased accuracy is paid for by increased time to perform the conversion.

Several devices have been used in conjunction with the COPS device in the previous sections. It is again recommended that the user refer to the specific data sheets of those devices when using any of those circuits. It must again be mentioned that the standard precautions when dealing with analog signals and circuits must be taken. These are described in the National Semiconductor Linear Applications Handbook and in the data sheets for the various linear devices. These precautions are especially significant when greater accuracy is desired.

The COPS family of microcontrollers has shown itself to be very versatile and powerful when used to perform analog to digital conversions. Most techniques are code efficient and the microcontroller itself is almost never the limiting factor. It is hoped that this document will provide some guidance when it is necessary to perform analog to digital conversion in a COPS system.

The COP444L Evaluation

National Semiconductor
COP Note 4
Leonard A. Distaso

The 444L-EVAL is a software program intended to be used with the COP444LP to demonstrate operating characteristics and facilitate user familiarization and evaluation of the COP444L and the COPSTM family in general. This software program is available on Dial-a-Helper.

The 444L-EVAL has two mutually exclusive operating modes: an up/down counter/timer or a simple music synthesizer. The state of pin L7 at power up determines the operating mode.

1.0 THE 444L-EVAL AS A SIMPLE MUSIC SYNTHESIZER

Figure 1 indicates the connection of the 444L-EVAL as a simple music synthesizer. As the diagram indicates, the connections required for operation are minimal. The os-

illator may be a crystal circuit using CKI and CKO; an external oscillator to CKI; or an RC network using CKI and CKO. As should be expected, the crystal circuit provides the greatest frequency stability and precision. The RC network will provide an acceptable oscillation frequency but that frequency will be neither precise nor stable over temperature and voltage. The external oscillator, of course, is as good as its source. The frequencies for the various notes and delay times are set up assuming that the oscillator frequency is 2 MHz. Three modes of operation are available in the music synthesizer mode: play a note; play one of four stored tunes; or record a tune for subsequent replay.

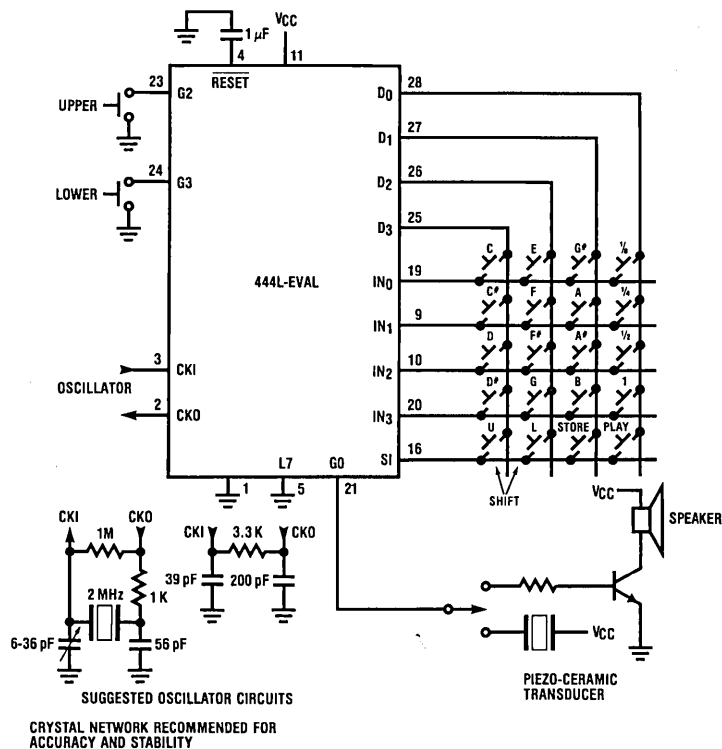

FIGURE 1. 444L-EVAL as Simple Music Synthesizer

TL/DD/6937-1

1.A. PLAY A NOTE

Twelve keys, representing the twelve notes in one octave, are labeled "C" through "B". Depressing a key causes a square wave of the corresponding frequency to output at GO. The user may drive a piezo-ceramic transducer directly with this signal. With the appropriate buffering, the user may use this signal to drive anything he wishes. A simple transistor driver is sufficient to drive a small speaker. The user can be as simple or as complex as he desires at this point—e.g. he can do some wave shaping, add an audio amplifier, and drive a high quality speaker.

The 444L-EVAL has a range of two and one-half octaves: the basic octave on the keyboard (which is middle C and the 11 notes above it in the chromatic scale), one full octave above the basic octave and one-half octave below the basic octave. The notes in the basic octave are played by depressing the appropriate key (one key at a time—the keyboard has no rollover provisions). A note in the upper octave is played by first depressing and releasing the U SHIFT key and then depressing the note key. Similarly, a note in the lower one-half octave is played by first depressing and releasing the L SHIFT key and then depressing the note key. Two other shift keys are present: UPPER and LOWER. All notes played while the UPPER key is held down will be in the upper octave. Similarly, note F# through B when played while the LOWER key is held down will be in the lower one-half octave. The lower octave notes C through F are not present and depressing any of these 6 keys while the LOWER key is held down or after depressing the L SHIFT key will play the note in the basic octave.

1.B. PLAY STORED TUNE

The 444L-EVAL can play four preprogrammed tunes. Depressing PLAY followed by "1/8", "1/4", "1/2", or "1" will cause one of these tunes to be played. The tunes are:

- PLAY 1 —Music Box Dancer
- PLAY 1/2 —Santa Lucia
- PLAY 1/4 —Godfather Theme
- PLAY 1/8 —Theme from Tchaikowsky Piano Concerto #1

1.C. RECORD A TUNE

Any combination of notes and rests up to a total of 48 may be stored in RAM for later replay. A note is stored by depressing the appropriate key(s), followed by the duration of the note (1/16 note, 1/8 note, 3/16 note, 1/4 note, 3/8 note, 1/2 note, 3/4 note, whole(1) note), followed by STORE. A rest is stored by selecting the duration and depressing STORE. The rests or durations of 1/16, 3/16, 3/8, and 3/4 are obtained by first depressing L SHIFT and then 1/8, 1/4, 1/2, or 1 respectively. When the tune is complete press PLAY followed by STORE. The tune will be played for immediate audition. Subsequent depression of PLAY and then STORE will play the last stored tune.

Only one tune may be stored, regardless of length. Attempts to store a new or second tune will erase the previously stored tune. There are no editing features in this

mode. (In a "real system" of this type some form of editing would be desirable. It would not be difficult to add editing features.)

Note: The accuracy of the tones produced is a function of the oscillator accuracy and stability. The crystal oscillator, or an accurate, stable external oscillator is recommended.

2.0. THE 444L-EVAL AS AN UP/DOWN COUNTER/TIMER

By connecting pin L7 to V_{CC} and providing power and oscillator the 444L-EVAL functions as an 8 digit binary/BCD up/down counter. In addition, an approximate 1 Hz signal is produced by the device. The 444L-EVAL can drive a single digit LED display directly. With the appropriate driver (COP472, COP470, MM5450/5451) the device can drive a 4 digit LCD, VF, or LED display. Any combination of these displays can be connected at any given time.

The binary/BCD and up/down modes are controlled by the states of input pins IN0 and IN2 as indicated below:

- IN0 = 1 (Default state) —BCD counter
- IN0 = 0 —Binary Counter
- IN2 = 1 (Default state) —Count Up
- IN2 = 0 —Count Down

The up/down control may be changed at any time. Changing the binary-BCD control during operation clears the counter before counting begins in the new mode.

Pins G2 and G3 provide display control to the user. He can choose to view either the most significant 4 digits of the counter or the least significant 4 digits of the counter. Further, the user can disable the update of the 4 digit displays. The controls are as follows:

- G2 = 1 (Default state) —Enable update of 4 digit displays
- G2 = 0 —Disable update of 4 digit displays
- G3 = 1 (Default state) —Display least significant 4 digits of counter
- G3 = 0 —Display most significant 4 digits of counter

The single digit LED display displays the least significant digit of the counter. (Note, the direct drive capability for the single digit LED display refers to a small LED digit—NSA1541A, NSA1166k, or equivalent.)

2.A. I/O MODE

The 444L-EVAL has the capability to allow the user to read or write the 8 digit counter through the L port. In the I/O mode, the single digit LED display is disabled. The 4 digit displays are not affected. In this mode pins D0 and IN3 are used for the handshaking sequence. D0 is a Ready/Write signal from the 444L-EVAL to the outside; IN3 is a Write/Acknowledge from the outside to the 444L-EVAL. Data I/O is via L0–L3 with L0 being the least significant bit. Data is standard BCD for the BCD counter mode or standard hex for the binary counter mode. The digit address is on pins L4–L6 with L4 being the least significant bit. Digit address

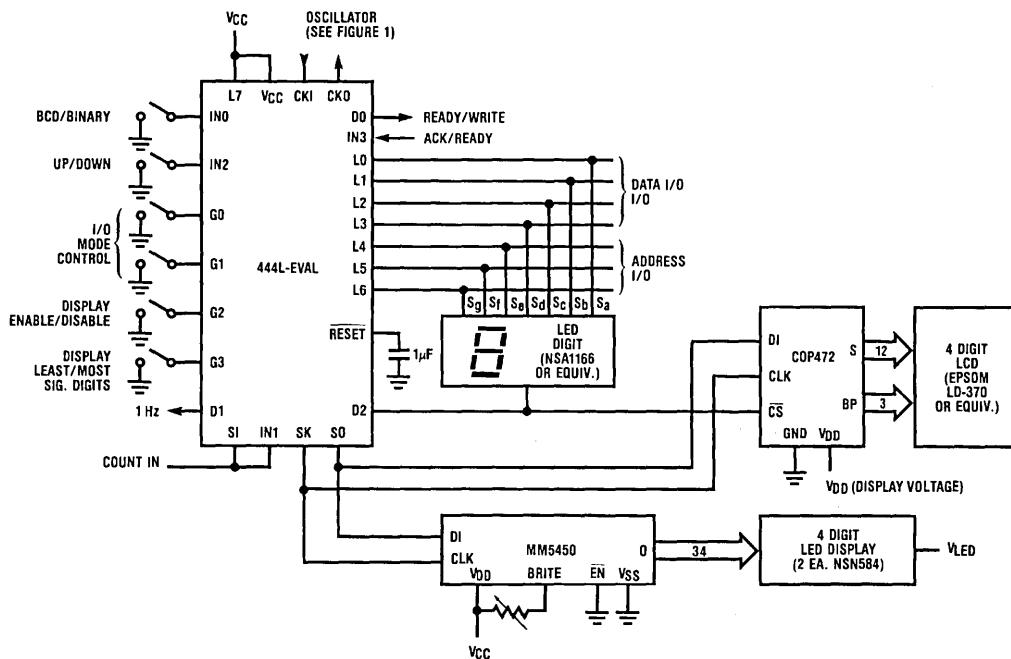

FIGURE 2. 444L-EVAL in Counter Mode

TL/DD/6937-2

0 is the least significant digit of the counter; digit address 7 is the most significant digit of the counter. The I/O modes are controlled by pins G0 and G1 as follows:

G0	G1	Output data with handshake, single digit LED off
0	0	Output data with handshake, single digit LED off
0	1	Input data with handshake, single digit LED off
1	0	Auto output, no handshake, single digit LED on
1	1	Default condition, No I/O, single digit LED displays least significant digit of counter

2.A.1. Output Data with Handshake

With this mode selected the 444L-EVAL will output data with a handshake sequence. Note that the outputting of data is relatively slow as the device is counting and updating displays between successive digit outputs.

Before data is output, or the next digit of the counter is output, the 444L-EVAL must see IN3 (Acknowledge or ready from the external world high). The Ready/Write pin (D0) is assumed to be high at this point. With D0 high and IN3 high, the device will output the data and digit address. After the data and address are output, the D0 line—functioning as a write strobe here—goes low. The 444L-EVAL then expects the signal at IN3 to go low indicating that the external world has read the data. When the device sees IN3 go low, D0 will be brought high indicating that the sequence

is ready to repeat as soon as IN3 goes high again. The counter digits are output sequentially from least significant digit (digit address 0) through most significant digit (digit address 7). The sequence will continuously repeat as long as this mode is selected.

2.A.2. Input Data with Handshake

The 444L-EVAL will take data supplied to it and load the counter. The sequence is similar to that described above for the output mode. The external device(s) supplies both the data and the digit address where that data is to be loaded. When sending data to the 444L-EVAL, the external circuitry must test that the device is ready to receive data (D0 high). Then the data and address should be presented at the L port. Then the Write signal (IN3) should be driven low. The 444L-EVAL will read the data and then drive D0 low. When D0 goes low, the external circuitry should bring IN3 high. After IN3 returns high, the 444L-EVAL will signal it is ready to receive data by sending D0 high. Note that this sequence is relatively slow. The 444L-EVAL is performing several operations between successive read operations.

2.A.3. Automatic Output Mode

In the automatic output mode, the single digit LED is on. It is not displaying the least significant digit of the counter in this mode. The display is on so that the user can connect this LED digit, select the automatic output mode, and observe the states of the L lines without having to put more sophisticated equipment or circuitry external to the 444L-EVAL. Segments a through d are pins L0 through L3; segments,

e, f, g are pins L4, L5, and L6. Thus the user can observe the digit address changing and observe the corresponding data.

In this mode, the state of pin IN3 is irrelevant. The 444L-EVAL sequentially outputs the digits of the counter.

D0 goes high when the data and address is being changed. D0 goes low when the data is valid. As in the other I/O modes, the process is slow. There is about 4 to 5 milliseconds between the successive digit outputs.

3.0 SELECTED OPTIONS

The 444L-EVAL has the following options selected:

GND	Option 1 = 0	
CKO	Option 2 = 0	CKO is clock generator output to crystal
CKI	Option 3 = 0	CKI oscillator input divide by 32
RESET	Option 4 = 0	Load device to V_{CC} on RESET
L7	Option 5 = 0	Standard output on L7
L6	Option 6 = 2	High current LED direct segment drive on L6
L5	Option 7 = 2	High current LED direct segment drive on L5
L4	Option 8 = 2	High current LED direct segment drive on L4
IN1	Option 9 = 0	Load device to V_{CC} on IN1
IN2	Option 10 = 0	Load device to V_{CC} on IN2
V_{CC}	Option 11 = 1	4.5V to 9.5V operation
L3	Option 12 = 2	High current LED direct segment drive on L3
L2	Option 13 = 2	High current LED direct segment drive on L2
L1	Option 14 = 2	High current LED direct segment drive on L1
L0	Option 15 = 2	High current LED direct segment drive on L0
SI	Option 16 = 0	Load device to V_{CC} on SI
SO	Option 17 = 2	Push-pull output on SO
SK	Option 18 = 2	Push-pull output on SK
IN0	Option 19 = 0	Load device to V_{CC} on IN0
IN3	Option 20 = 0	Load device to V_{CC} on IN3
G0	Option 21 = 0	Very high current standard output on G0
G1	Option 22 = 2	High current standard output on G1
G2	Option 23 = 4	Standard LSTTL output on G2
G3	Option 24 = 4	Standard LSTTL output on G3
D3	Option 25 = 0	Very high current standard output on D3

D2	Option 26 = 0	Very high current standard output on D2
D1	Option 27 = 0	Very high current standard output on D1
D0	Option 28 = 0	Very high current standard output on D0
	Option 29 = 0	Standard TTL input levels on L
	Option 30 = 0	Standard TTL input levels on IN
	Option 31 = 0	Standard TTL input levels on G
	Option 32 = 0	Standard TTL input levels on SI
	Option 33 = 1	Schmitt trigger inputs on RESET
	Option 34 = 0	CKO input levels, not used here
	Option 35 = 0	COP444L
	Option 36 = 0	Normal RESET operation

4.0 CONCLUSION

The 444L-EVAL demonstrates much of the capability of the COP444L. It does not indicate the limits of the device by any means. The I/O features were included to demonstrate that capability. The fact that they are slow is due strictly to the program. If such I/O capability were a necessary part of an application it could be accomplished much much faster than was done here. The counter modes are quite versatile and are generally self explanatory. It was fairly easy to provide a counter with the versatility of that included here. The music synthesis mode demonstrates clearly the program efficiency of the device.

The 444L-EVAL is intended for demonstration. There is no question that aspects of its operation could be improved and tailored to a specific application. It is unlikely that this particular combination of features would be found in any one application. It is also interesting to note that the program memory in the device is not full. There is still a significant amount of room left in the ROM. This should serve to make it clear that the capabilities of the device have not been stretched at all in order to include these demonstration functions.

4.0 CONCLUSION

1.0 INTRODUCTION

COPS microcontrollers will operate with a wide variety of oscillator circuits. This paper focuses on two of the oscillator options available on COPS microcontrollers: the internal RC oscillator, and the crystal or inverter oscillator. The typical behavior of the RC oscillator with temperature and voltage (and typical values of R and C) is documented. For the crystal or inverter option, circuit configurations (RC, RL, RLC, R, LC, L) are presented which will allow the microcontroller to operate properly without the use of ceramic resonator or crystal.

The passive components used were inexpensive, uncompensated devices: standard carbon resistors, ceramic or foil capacitors, and air core or iron core inductors. To provide reasonably clear data on the characteristics of the microcontroller itself, no attempt at compensation for the external components was made.

2.0 RC OSCILLATOR OPTION

With the RC oscillator option selected, the graphs in *Figures 1* through *6* indicate the variation of the instruction cycle time of the microcontroller with temperature and voltage. Typical R and C values, as recommended in the respective device data sheets, were used. The graphs are composite graphs reflecting the worst case variations of the devices tested. Therefore, the graphs show a percentage change of the instruction cycle time from a base or reference value. Where the results are plotted against voltage the reference is the value at $V_{CC} = 5V$. Where the results are plotted against temperature, the reference is the value at $T = 20^{\circ}C$. A positive percent variation indicates a longer instruction cycle time and therefore a slower oscillator frequency. Similarly, a negative percent variation indicates a shorter instruction cycle time and therefore a faster oscillator frequency.

The measurements were taken by holding the RESET pin of the device low and measuring the period of the waveform at pin SK. In this mode the SK period is the instruction cycle time. For divide by 4 the oscillator frequency is given by the following:

$$\text{frequency} = \frac{4}{\text{SK period}}$$

Measurements were taken at temperatures between $-40^{\circ}C$ and $+85^{\circ}C$ and at V_{CC} values between 4.5V and 9.5V. However, the reader must remember that the COP400 series is specified only between $0^{\circ}C$ and $+70^{\circ}C$. The reader must also remember that the COP420 is specified at V_{CC} levels between 4.5V and 6.3V only. The data here is usable for the COP300 series, which is specified at the extended temperature range of $-40^{\circ}C$ to $+85^{\circ}C$. However, the reader must keep in mind the generally more restricted V_{CC} range for some of the various COP300 series microcontrollers.

The graphs in *Figures 1* through *6* reflect the variation of the microcontroller only. The resistor and capacitor were not in the temperature chamber with the COPS device. Obviously, the results will be affected by the variation of the R and C with temperature. However, this can vary dramatically with the type of components used. The user will have to combine the data here with the characteristics of the external components used to determine what type of variation may be expected in his system.

3.0 CRYSTAL OR INVERTER OPTION

With the crystal or inverter option selected on the COPS microcontroller there is, effectively, an inverter between the CKI and CKO pins. CKI is the input to the inverter and CKO is the output. Various passive circuits were connected between CKI and CKO and the results documented. Of the operational circuits, a subset was tested over temperature with the microcontroller only in the temperature chamber. A smaller subset was tested over temperature with both the microcontroller and the oscillator network in the temperature chamber.

The data with the oscillator network in the temperature chamber is obviously highly dependent on the particular components used. This data was taken with standard, inexpensive, uncompensated components. Neither high precision nor high stability components were used. This data is included only to provide the user with some very general indication of how the oscillator frequency may vary with temperature in a real system.

3.1 COP420/COP402

Except for the ROM, the COP420 and COP402 are equivalent devices. The internal circuitry of each device is identical. Therefore, data taken for one of the devices is equally

applicable to the other. The following discussion will refer to the COP420 but all such references apply equally well to the COP402. Similarly, the graphs for the COP420 apply to the COP402 and *vice versa*.

With the crystal option selected, the COP420 oscillator circuitry will readily oscillate with almost any circuit configuration between CKI and CKO. What difficulty there is lies in finding the network of the device. With the appropriate divide option selected, oscillator frequencies between 800 kHz and 4 MHz are valid for the COP420. No data was taken for any network that produced an oscillation frequency outside the valid range.

3.1.1 L, LC, and RLC Networks

Various L, LC, and RLC networks were connected with varying results. Certain networks produced results much more stable than the RC networks; others were no better than the RC networks. With a single inductor connected between CKI and CKO, frequencies between 1 MHz and 4 MHz were easily obtained. However, the input gate capacitance at CKI (typically 5 pF to 10 pF) and the series resistance of the inductance become factors that impact the oscillation frequency and its stability over temperature.

The addition of a capacitor between CKI and ground tends to reduce the effects of the internal gate capacitance. For the single L, single C network of this type, the capacitor value should be greater than about 50 pF to begin to effectively swamp out the effects of the input gate capacitance. As might be expected, LC combinations which had their resonant frequencies within the valid COP420 frequency range produced the best results.

The addition of another capacitor(s) to the basic two-component LC network, as shown in *Figure III.1*, produced very good results. Varying the capacitor values in these networks — especially those capacitors between CKI and ground and CKO and ground — provided a great deal of control over the oscillation frequency. In *Figure III.1*, varying C1 from 25 pF to 0.01 μ F produced oscillation frequencies between about 3 MHz and 1.6 MHz (C2 = 25 pF, L = 56 μ H). In *Figure III.2*, with C1 = 330 pF, L = 56 μ H, and C2 = 27 pF, varying C3 between 10 pF and 0.003 μ F produced oscillation frequencies between about 2 MHz and 1.1 MHz. Varying C2 in *Figure III.3* produced a similar kind of control.

As the graphs indicate, various types of RLC networks were also tried. The range of possible usable circuits here is limited only by the user's imagination and his favorite type of RLC oscillator circuit. When their resonant frequency is

within the valid frequency range of the COP420, LC and RLC networks can be a very effective substitute for a crystal. The only potential problem is that a good RLC, or even LC, oscillator circuit may not be a cost-effective substitute for a crystal in a COP420 system. The user will have to make that determination.

3.2 COP420L

The valid input frequency range for the COP420L, with the appropriate divide option selected, is between 200 kHz and 2.097 MHz. With the crystal option selected the COP420L oscillated much less readily than the COP420.

The LC networks gave outstanding results with the COP420L. With the simple two-component LC network shown in the graphs, holding C at 50 pF and varying L from 200 μ H to 700 μ H gave oscillation frequencies from about 2 MHz to 1 MHz. Holding L at 390 μ H and varying C from 10 pF to 700 pF gave oscillation frequencies of about 2 MHz to 1.6 MHz. Similar results were obtained when a capacitor was placed in parallel with the inductance.

3.3 COP410L

The COP410L has a valid input frequency range of 200 kHz to 530 kHz.

The LC networks also gave very good results. With the simple LC network shown in the graphs, holding L at 4700 μ H and varying C from 25 pF to 0.003 μ F gave oscillation frequencies of about 460 kHz to 225 kHz.

3.4 GENERAL NOTES

With the crystal or inverter option selected on COPS microcontrollers, a wide variety of networks may be used in place of the ceramic resonator or crystal.

LC and RLC networks can be used in any of the devices. Appropriately designed, these networks will provide a stable oscillation frequency for the microcontroller. The user will have to allow for the variation of the external components with temperature when using these networks. The problems with networks such as these is that they may not be cost-effective alternatives to the crystal or resonator, especially if high stability, temperature compensated components are used. The user will have to make the determination of cost-effectiveness.

A final note is that all of these networks place a load on the CKO output. If the signal from CKO is needed elsewhere in the system and a circuit similar to one of those discussed in this document is used, it will probably be necessary to buffer the CKO output.

4.0 Conclusion

The networks described are generally simple and inexpensive and have all been observed to be functional. The results obtained provide greater flexibility in the oscillator selection in a COPs system and gives the user some general indication as to what may be expected with the various circuits described.

1.0 Triac Control

The COP400 single-chip controller family members provide computational ability and speed which is more than adequate to intelligently manage power control. These controllers provide digital control while low cost and short turn-around enhance COPST[™] desirability. The COPS controllers are capable of 4 μ s cycle times which can provide more than adequate computational ability when controlling 60 Hz line voltage. Input and output options available on the COPS devices can contour the device to apply in many electrical situations. A more detailed description of COPS qualifications is available in the COP400 data sheets.

The COPS controller family may be utilized to manage power in many ways. This paper is devoted to the investigation of low cost triac interfaces with the COP400 family microcontroller and software techniques for power control applications.

1.1 BASIC TRIAC OPERATION

A triac is basically a bidirectional switch which can be used to control AC power. In the high-impedance state, the triac blocks the principal voltage across the main terminals. By pulsing the gate or applying a steady state gate signal, the triac may be triggered into a low impedance state where conduction across the main terminals will occur. The gate signal polarity need not follow the main terminal polarity; however, this does affect the gate current requirements. Gate current requirements vary depending on the direction of the main terminal current and the gate current. The four trigger modes are illustrated in *Figure 1*.

FIGURE 1. Gate Trigger Modes. Polarities Referenced to Main Terminal 1.

TL/DD/6939-1

3

The breakover voltage (V_{BO}) is specified with the gate current (I_{GT}) equal to zero. By increasing the gate current supplied to the triac, V_{BO} can be reduced to cause the triac to go into the conduction or on state. Once the triac has entered the on state the gate signal need not be present to sustain conduction. The triac will turn itself off when the main terminal current falls below the minimum holding current required to sustain conduction (I_H).

A typical current and voltage characteristic curve is given in *Figure 2*. As can be seen, when the gate voltage and the main terminal 2 (MT2) voltages are positive with respect to MT1 the triac will operate in quadrant 1. In this case the trigger circuit sources current to the triac (I+ MODE).

TL/DD/6939-2

FIGURE 2. Voltage-Current Characteristics

After conduction occurs the main terminal current is independent of the gate current; however, due to the structure of the triac the gate trigger current is dependent on the direction of the main terminal current. The gate current requirements vary from mode to mode. In general, a triac is more easily triggered when the gate current is in the same direction as the main terminal current. This can be illustrated in the situation where there is not sufficient gate drive to cause conduction when MT2 is both positive and negative. In this case the triac may act as a single direction SCR and conduction occurs in only one direction. The trigger circuit must be designed to provide trigger currents for the worst case trigger situation. Another reason ample trigger current must be supplied is to prevent localized heating within the pellet and speed up turn-on time. If the triac is barely triggered only a small portion of the junction will begin to conduct, thus causing localized heating and slower turn-on. If an insufficient gate pulse is applied damage to the triac may result.

1.2 TRIGGERING

Gate triggering signals should exceed the minimum rated trigger requirements as specified by the manufacturer. This is essential to guarantee rapid turn-on time and consistent operation from device to device.

Triac turn-on time is primarily dependent on the magnitude of the applied gate signal. To obtain decreased turn-on times a sufficiently large gate signal should be applied. Faster turn-on time eliminates localized heat spots within the pellet structure and increases triac dependability.

Digital logic circuits, without large buffers, may not have the drive capabilities to efficiently turn on a triac. To insure proper operation in all firing situations, external trigger circuitry might become necessary. Also, to prevent noise from disturbing the logic levels, AC/DC isolation or coupling techniques must be utilized. Sensitive gate triacs which require minimal gate input signal and provide a limited amount of main terminal current may be driven directly. This paper will focus on 120V_{AC} applications of power control.

1.3 ZERO VOLTAGE DETECTION

In many applications it is advantageous to switch power at the AC line zero voltage crossing. In doing this, the device being controlled is not subjected to inherent AC transients. By utilizing this technique, greater dependability can be obtained from the switching device and the device being switched. It is also sometimes desirable to reference an event on a cyclic basis corresponding to the AC line frequency. Depending on the load characteristics, switching times need to be chosen carefully to insure optimal performance. Triac controlled AC switching referenced to the AC 60 Hz line frequency enables precise control over the conduction angle at which the triac is fired. This enables the COPS device to control the power output by increasing or decreasing the conduction angle in each half cycle.

A wide variety of zero voltage detection circuits are available in various levels of sophistication. COPS devices, in most cases, can compensate for noisy or semi-accurate ZVD circuits. This compensation is utilized in the form of debounce and delay routines. If a noisy transition occurs near zero volts the COPS device can wait for a valid transition period specified by the maximum amount of noise present. Some software considerations are presented in the software section and are commented upon. The minimal detection circuit is shown in *Figure 9*.

1.4 DIRECT COUPLE

Isolation associated problems can be overcome by means of direct AC coupling. One such method is illustrated in *Figure 3*. This circuit incorporates a half-wave rectifier in conjunction with a filter capacitor to provide the logic power supply. The positive half-cycle is allowed to drop across the zener diode and be filtered by the capacitor. This creates a low cost line interface; however, only a limited supply current is available. In order to control the current capabilities of this circuit the series resistor must be modified. However, as more current is required, the power that must be dissipated in the series resistor increases. This increases the power dissipation requirements of the series resistor and the system cost. For applications which require large current sources an alternative method is advisable. In order to assure consistent operation, power supply ripple must be mini-

mized. COPS devices can be operated over a relatively wide power supply range. However, excessive ripple may cause an inadvertent reset operation of the device.

TL/DD/6939-3

FIGURE 3. AC Direct Couple

1.5 PULSE TRANSFORMER INTERFACE

Digital logic control of triacs is easily accomplished by triggering through pulse transformers or optical coupling. The energy step-up gained by using a pulse transformer should provide a more than adequate gate trigger signal. This complies with manufacturers' suggested gate signal requirements. Pulse transformers also provide AC/DC isolation necessary in control logic interfaces. Minimal circuit interface to the pulse transformer is required as shown in Figure 4. Optical coupling circuits provide isolation, and in some cases adequate gate drive capabilities.

TL/DD/6939-4

FIGURE 4. Pulse Transformer Interface

A logic controlled pulse is applied to the base of the transistor to switch current through the primary of the pulse transformer. The transformer then transfers the signal to the secondary and causes the triac to fire. The energy transfer that is now available on the secondary is more than adequate to turn on the triac in any of its operating modes. When the pulse transformer is switched off a reverse EMF is generated in the primary coil which may cause damage to the transistor. The diode across the primary serves to protect the collector junction of the switching transistor. Another major advantage is AC isolation; the gate of the triac is now completely isolated from the logic portion of the circuit.

1.6 FALSE TURN-ON

When switching an inductive load, voltage spikes may be generated across the main terminals of the triac which have

the potential of a non-gated turn-on of the triac. This creates the undesirable situation of limited control of the system. In a system with an inductive load the voltage leads the current by a phase shift corresponding to the amount of inductance in the motor. As the current passes near zero, the voltage is at a non-zero value, offset due to the phase shift. When the principal current through the triac pellet decreases to a value not capable of sustaining conduction the triac will turn off. At this point in time the voltage across the terminals will instantaneously attain a value corresponding to the phase shift caused by the inductive load. The rapid decay of current in the inductor causes an $L di/dt$ voltage applied across the terminals of the triac. Should this voltage exceed the blocking voltage specified for the triac, a false turn-on will occur.

In order to avoid false turn-on, a snubber network must be added across the terminals to absorb the excess energy generated by this situation. A common form of this network is a simple RC in series across the terminals. In order to select the values of the network it is necessary to determine the peak voltage allowable in the system and the maximum dV/dt stress the triac can withstand. One approach to obtaining the optimal values for R_S and C_S is to model the effective circuit and solve for the triac voltage. The snubber in conjunction with the load can now be modeled as an RLC network. Due to the two storage elements (L motor, C snubber) a second order differential equation is generated. Rather than approach this problem from a computer standpoint it becomes much easier to obtain design curves generated for rapid solution of this problem. These design curves are available in many triac publications. (For instance, see RCA application note AN 4745.)

2.0 Software Techniques

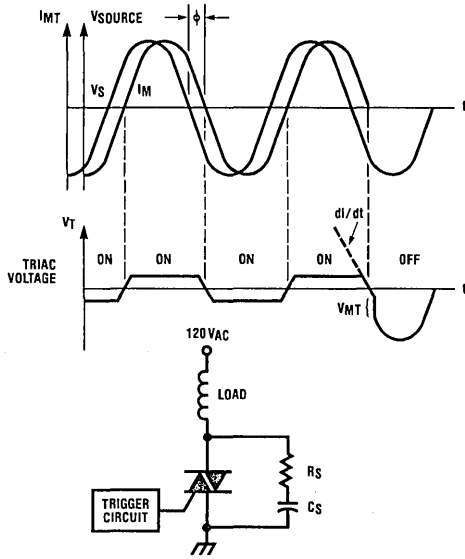

2.1 ZERO VOLTAGE DETECTION

In order to intelligently control triacs on a cyclic basis, an accurate time base must be defined. This may be in the form of an AC, 60 Hz sync pulse generated by a zero voltage detection circuit or a simple real time clock. The COP400 series microcontrollers are suited to accommodate either of these time base schemes while accomplishing auxiliary tasks.

Zero voltage detection is the most useful scheme in AC power control because it affords a real time clock base as well as a reference point in the AC waveform. With this information it is possible to minimize RFI by initiating power-on operations near the AC line voltage zero crossing. It is also possible to fire the triac for only a portion of the cycle, thus utilizing conduction angle manipulation. This is useful in both motor control and light intensity control.

Sophisticated zero voltage detection circuits which are capable of discriminating against noise and switch precisely at zero crossing are not necessary when used in conjunction with a COPS device. COPS software is capable of compensating for noisy or semi-accurate zero voltage detection circuits. This can be accomplished by introducing delays and debounce techniques in the software routines. With a given reference point in the AC waveform it now becomes easy

to divide the waveform to efficiently allocate processing time. These techniques are illustrated in the code listing at the end of this paper.

TL/DD/6939-5

FIGURE 5. Current Lag Caused by Inductive Load, Snubber Circuit

2.2 PROCESSING TIME ALLOCATIONS

Half Cycle Approach

In order to accomplish more than triac timing, dead delay time must be turned into computation time. It appears that the controller is occupied totally by time delays, which leaves a very limited amount of additional control capability. There are, however, many ways to accomplish auxiliary tasks simultaneously.

On each half cycle an initial delay is incorporated to space into the cycle. This dead time may be put to use and very little voltage to the load is sacrificed. For example, if the load is switched on at $\pi/4$ RAD, the maximum applied RMS voltage to the load is $114V_{RMS}$ (assuming $V_{SUPPLY} = 120V_{RMS}$). This is illustrated in the figure below.

TL/DD/6939-6

FIGURE 6. Full Cycle Approach

If a delay of $\pi/4$ RAD (45 degrees) is inserted after each zero crossing detection the RMS voltage to the load can be determined in the following manner:

$$V_{LOAD} = \sqrt{\frac{(120\sqrt{2})^2}{(2)\pi} (2) \int_{\pi/4}^{\pi} \sin^2(a) da}$$

$$V_{LOAD} = \sqrt{\frac{(120\sqrt{2})^2}{(2)\pi} (2) (1.428)}$$

$$V_{LOAD} = 114.4 V_{RMS}$$

$$\pi/4 \text{ RAD} = 45 \text{ degrees} \quad @60 \text{ Hz} \quad t = 2.08 \text{ ms}$$

As can be seen the dead time on each half cycle can be 2.08 ms and the load will still see $114.4 V_{RMS}$ of a V_{SUPPLY} of $120 V_{RMS}$. If this approach is implemented the initial delay of 2.08 ms can be used as computation time. The number of instructions which can be executed when operating at $4 \mu s$ instruction cycle time is:

$$2.08 \text{ ms} / 4 \mu s = 520 \text{ instructions}$$

(130 instructions at $16 \mu s$ cycle time)

Full Cycle Approach

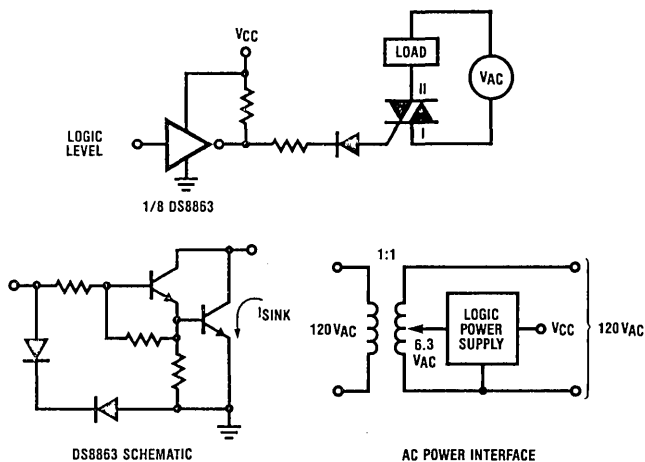

The methods of half cycle and full cycle triggering are very similar in procedure. The main difference is that all timing is referenced from only one (of the two) zero voltage detection transition in each full AC cycle. For most all applications, when varying the conduction angle it is desirable to fire at the same conduction angle each half cycle to maintain a symmetric applied voltage. In order to accomplish this the triac may be fired twice from one reference point. When applying this technique an 8.33 ms delay must be executed to maintain the symmetric applied voltage. This approach provides the most auxiliary computation time in that the 8.33 ms delay may be turned into computational time. The basic flow for this technique is illustrated below.

TL/DD/6939-7

FIGURE 7. Full Cycle Approach

In the above example the zero crossing pulse is debounced on the one-to-zero transition, thus marking the beginning of a full cycle. Once this transition has been detected, an ini-

TL/DD/6939-8

FIGURE 8. Steady State Triggering

tial delay of $\pi/4$ RAD is incorporated and the triac is fired. At this time exactly 8.33 ms is available until the triac need be triggered again. This will provide a symmetric voltage to the load only if the delay is 8.33 ms. During this period the number of instructions which can be executed when operating at $4 \mu\text{s}$ is:

$$8.33 \text{ ms} / 4 \mu\text{s} = 2082$$

(520 instructions at $16 \mu\text{s}$)

An alternative approach may be to take the burden from the COPS device by using peripheral devices such as static display controllers, external latches, etc.

2.3 STEADY STATE TRIGGERING

It is possible to trigger a triac with a steady state logic level. This is accomplished by allowing the triac gate to sink or source current during the desired on-time. When utilizing this method it becomes easier to trigger the triac and leave it on for many cycles without having to execute code to retrigger. This approach is advantageous when the triac must be fired is for relatively long periods and conduction angle firing is not desired, thus more time is available to accomplish auxiliary tasks. A steady state on or off signal and external circuitry can accomplish triac firing and free the processor for other tasks. If it is desired to use a pulse
