IMPORTANT NOTICE

Texas Instruments (TI) reserves the right to make changes in the devices or the device specifications identified in this publication without notice. TI advises its customers to obtain the latest version of device specifications to verify, before placing orders, that the information being relied upon by the customer is current.

TI warrants performance of its semiconductor products to current specifications in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems such testing necessary to support this warranty. Unless mandated by government requirements, specific testing of all parameters of each device is not necessarily performed.

In the absence of written agreement to the contrary, TI assumes no liability for TI applications assistance, customer's product design, or infringement of patents or copyrights of third parties by or arising from use of semiconductor devices described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor devices might be or are used.

Specifications contained in this data book supersede all data for these products published by TI in the United States before September 1986.

INTRODUCTION

Texas Instruments offers a broad line of Interface and Speech Products serving analog signal conditioning/processing and interface applications that may require higher currents and/or higher voltages than can be achieved with conventional digital devices.

TI's Interface circuits represent technologies from classic bipolar through BIFET, Advanced Low-Power Schottky (ALS), IMPACT™, LinCMOS™, and ADVANCED LinCMOS™ processes. The ALS and IMPACT™ oxide-isolated technologies provide the Interface family with improved speed-power characteristics. LinCMOS™ and ADVANCED LinCMOS™ technologies feature a step-function improvement in impedance, speed, power dissipation, and threshold stability.

TI's Interface products include such devices as data transmission circuits that tie computers and their associated peripherals together according to a set of industry (EIA) standards that prescribe line length, data rates, and propagation delays, among other things. With the recent growth of the flat panel display market, TI's high-voltage display drivers are providing cost-effective and reliable solutions to the AC-plasma, vacuum-fluorescent, and electroluminescent display markets. Analog-to-digital and digital-to-analog converters are offered as peripheral support chips in microprocessor-based systems and DSP (digital signal processing) related analog interfaces. TI's line of high-current motor/printhead and MOSFET drivers combine logic control and high current-drive capability on one IC.

During the last decade, TI has produced a wide range of speech-generating devices based on the technique of pitch-excited linear predictive coding (LPC). This technique extracts data from original recorded speech to define the control parameters for a mathematical model of the vocal tract. The speech generated from this model retains all the inflection and voice characteristics of the original spoken phrase while minimizing digitized data storage requirements; and it does not exhibit the robotic quality often associated with synthesis-by-rule systems.

This data book provides information on the following types of products:

- Analog Switches
- High-Current Actuators and Peripheral Drivers
- Switched-Capacitor General Purpose Filters
- A/D and D/A Converters
- High-Voltage Display Drivers
- IBM 360/370 I/O Line Drivers
- IEEE-488 (GPIB) Octal Bus Transceivers
- RS-422-A Line Drivers
- RS-422-A, RS-423-A, and RS-485 Line Receivers
- LPC10 and LPC12 Voice Synthesis Functions on a Chip
- One-Chip Speech System
- Auxiliary Speech Memories

These products cover the dynamic development of linear circuits from the classical operational amplifier to the high-performance A/D and D/A converters and speech-generating devices. New surface-mount packages (8 to 84 leads) include both ceramic and plastic chip carriers, and the small-outline (D) plastic packages that optimize board density with minimum impact on power-dissipation capability.

The Selection Guide includes a functional description of each product, and to assist the design engineer, the Guide is organized into sections containing information on key parameters and packaging. Ordering information and mechanical data are in Appendix B.

IMPACT™, LinCMOS™, and ADVANCED LinCMOS™ are trademarks of Texas Instruments Incorporated.

During the last decade, TI has produced one of the largest IC socket families. TI's sockets include every type and size socket in common use today and are available in a wide choice of contact materials and designs. Details on TI's sockets are presented in Appendix B.

While this volume offers design and specification data only for Interface and Speech components, complete technical data for any TI semiconductor product is available from your nearest TI Field Sales Office, local authorized TI distributor, or by writing directly to:

[†] Includes access time.

[‡] Analog/digital inputs can be used either as digital logic inputs or inputs for analog to digital conversion. For example: The TLC532/3A can have 11 analog inputs, 5 analog inputs and 6 digital inputs, or any combination in between.

[§] Differential Input.

[¶] The TLC32040 has two differential inputs for the 14 bit A/D and a serial port input for the 14 bit D/A.

[#] The A/D conversion accuracy for this device is measured in terms of signal-to-quantization distortion and also in LSB over certain converter ranges. Please refer to the data sheet.

CROSS-REFERENCE GUIDE
(manufacturers arranged alphabetically)

Replacements were based on similarity of electrical and mechanical characteristics as shown in currently published data. Interchangeability in particular applications is not guaranteed. Before using a device as a substitute, the user should compare the specifications of the substitute device with the specifications of the original.

Texas Instruments makes no warranty as to the information furnished and buyer assumes all risk in the use thereof. No liability is assumed for damages resulting from the use of the information contained in this list.

ADC0803, ADC0805 8-BIT ANALOG-TO-DIGITAL CONVERTERS WITH DIFFERENTIAL INPUTS

D2754, NOVEMBER 1983—REVISED SEPTEMBER 1986

- 8-Bit Resolution
- Ratiometric Conversion
- 100 μ s Conversion Time
- 135 ns Access Time
- Guaranteed Monotonicity
- High Reference Ladder Impedance
8 k Ω Typical
- No Zero Adjust Requirement
- On-Chip Clock Generator
- Single 5-Volt Power Supply
- Operates with Microprocessor or as Stand-Alone
- Designed to be Interchangeable with National Semiconductor and Signetics ADC0803 and ADC0805

N DUAL-IN-LINE PACKAGE
(TOP VIEW)

description

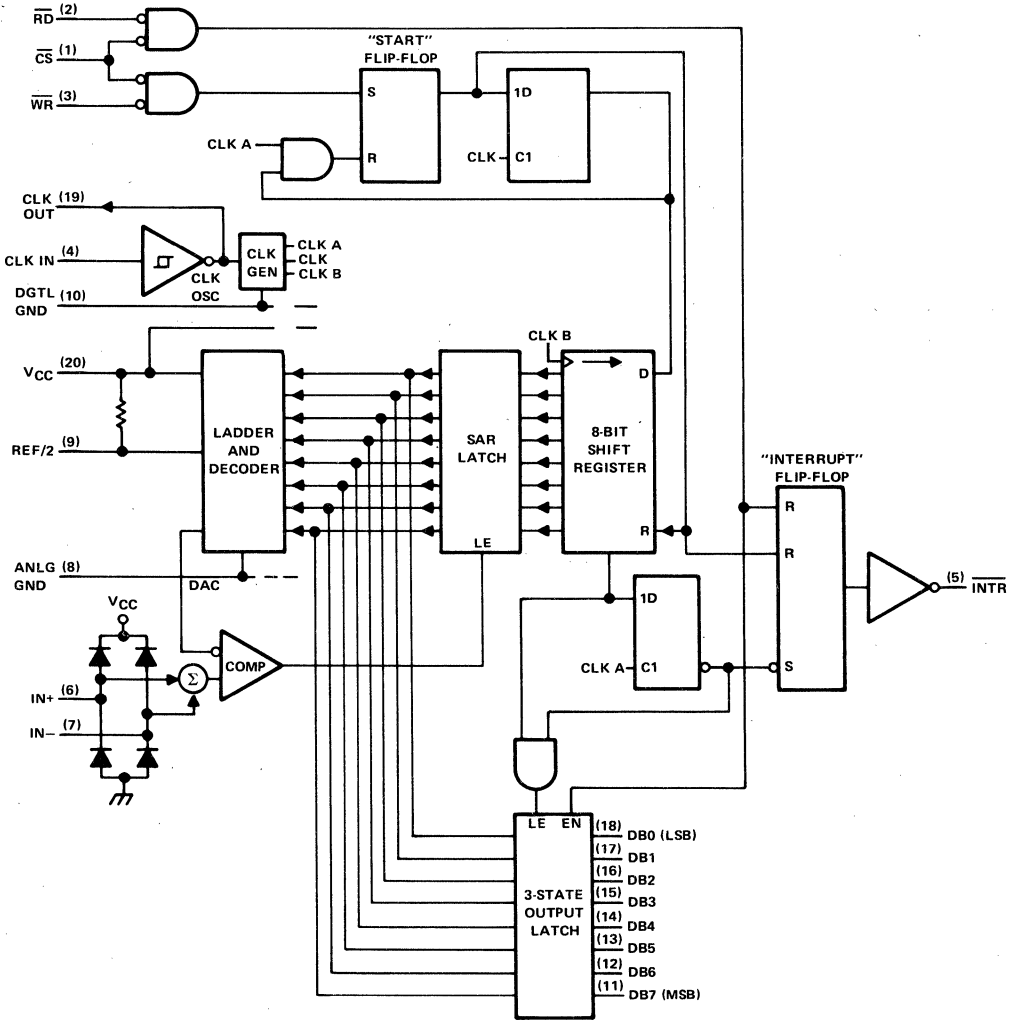

The ADC0803 and ADC0805 are CMOS 8-bit successive-approximation analog-to-digital converters that use a modified potentiometric (256R) ladder. These devices are designed to operate from common microprocessor control buses, with the three-state output latches driving the data bus. The devices can be made to appear to the microprocessor as a memory location or an I/O port. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

A differential analog voltage input allows increased common-mode rejection and offset of the zero-input analog voltage value. Although a reference input (REF/2) is available to allow 8-bit conversion over smaller analog voltage spans or to make use of an external reference, ratiometric conversion is possible with the REF/2 input open. Without an external reference, the conversion takes place over a span from V_{CC} to analog ground (ANLG GND). The devices can operate with an external clock signal or, with an additional resistor and capacitor, can operate using an on-chip clock generator.

The ADC0803I and ADC0805I are characterized for operation from -40°C to 85°C . The ADC0803C and ADC0805C are characterized from 0°C to 70°C .

Data Acquisition Circuits

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC} (see Note 1)	6.5 V
Input voltage range \overline{CS} , \overline{RD} , \overline{WR}	-0.3 V to 18 V
Other inputs	-0.3 V to $V_{CC} + 0.3$ V
Output voltage range	-0.3 V to $V_{CC} + 0.3$ V
Operating free-air temperature range: ADC080_I	-40°C to 85°C
ADC080_C	0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

NOTE 1: All voltage values are with respect to digital ground (DGTL GND) with DGTL GND and ANLG GND connected together unless otherwise noted.

recommended operating conditions

	MIN	NOM	MAX	UNIT	
Supply voltage, V_{CC}	4.5	5	6.3	V	
Analog input voltage (see Note 2)	-0.05		$V_{CC} + 0.05$	V	
Voltage at REF/2 (see Note 3), $V_{REF/2}$	0.25	2.5		V	
High-level input voltage at \overline{CS} , \overline{RD} , or \overline{WR} , V_{IH}	2		15	V	
Low-level input voltage at \overline{CS} , \overline{RD} , or \overline{WR} , V_{IL}			0.8	V	
Analog ground voltage (see Note 4)	-0.05	0	1	V	
Clock input frequency (see Note 5), f_{clock}	100	640	1460	kHz	
Duty cycle for f_{clock} above 640 kHz (see Note 5)	40%		60%		
Pulse duration, clock input (high or low) for f_{clock} below 640 kHz, $t_w(CLK)$	275	781		ns	
Pulse duration, \overline{WR} input low, $t_w(WR)$		100		ns	
Operating free-air temperature, T_A		ADC080_I	-40	85	°C
		ADC080_C	0	70	

- NOTES: 2. When the differential input voltage ($V_{I+} - V_{I-}$) is less than or equal to 0 V, the output code is 0000 0000.
3. The internal reference voltage is equal to the voltage applied to REF/2 or approximately equal to one-half of the V_{CC} when REF/2 is left open. The voltage at REF/2 should be one-half the full-scale differential input voltage between the analog inputs. Thus, the differential input voltage range when REF/2 is open and $V_{CC} = 5$ V is 0 V to 5 V. $V_{REF/2}$ for an input voltage range from 0.5 V to 3.5 V (full-scale differential voltage of 3 V) is 1.5 V.
4. These values are with respect to DGTL GND.
5. Total unadjusted error is guaranteed only at an f_{clock} of 640 kHz with a duty cycle of 40% to 60% (pulse duration 625 ns to 937 ns). For frequencies above this limit or pulse duration below 625 ns, error may increase. The duty cycle limits should be observed for an f_{clock} greater than 640 kHz. Below 640 kHz, this duty cycle limit can be exceeded provided $t_w(CLK)$ remains within limits.

Data Acquisition Circuits

The ADC0803 and ADC0805 each contain a circuit equivalent to a 256-resistor network. Analog switches are sequenced by successive-approximation logic to match an analog differential input voltage ($V_{in+} - V_{in-}$) to a corresponding tap on the 256R network. The most significant bit (MSB) is tested first. After eight comparisons (64 clock periods), an eight-bit binary code (1111 1111 = full scale) is transferred to an output latch and the interrupt (\overline{INTR}) output goes low. The device can be operated in a free-running mode by connecting the \overline{INTR} output to the write (\overline{WR}) input and holding the conversion start (\overline{CS}) input at a low level. To ensure start-up under all conditions, a low-level \overline{WR} input is required during the power-up cycle. Taking \overline{CS} low anytime after that will interrupt a conversion in process.

When the \overline{WR} input goes low, the internal successive approximation register (SAR) and eight bit shift register are reset. As long as both \overline{CS} and \overline{WR} remain low, the analog-to-digital converter will remain in a reset state. One to eight clock periods after \overline{CS} or \overline{WR} makes a low-to-high transition, conversion starts.

When the \overline{CS} and \overline{WR} inputs are low, the start flip-flop is set and the interrupt flip-flop and eight bit register are reset. The next clock pulse transfers a logic high to the output of the start flip-flop. The logic high is ANDed with the next clock pulse placing a logic high on the reset input of the start flip-flop. If either \overline{CS} or \overline{WR} have gone high, the set signal to the start flip-flop is removed causing it to be reset. A logic high is placed on the D input of the eight-bit shift register and the conversion process is started. If the \overline{CS} and \overline{WR} inputs are still low, the start flip-flop, the eight-bit shift register, and the SAR remain reset. This action allows for wide \overline{CS} and \overline{WR} inputs with conversion starting from one to eight clock periods after one of the inputs goes high.

When the logic high input has been clocked through the eight-bit shift register, completing the SAR search, it is applied to an AND gate controlling the output latches and to the D input of a flip-flop. On the next clock pulse, the digital word is transferred to the three-state output latches and the interrupt flip-flop is set. The output of the interrupt flip-flop is inverted to provide an \overline{INTR} output that is high during conversion and low when the conversion is completed.

When a low is at both the \overline{CS} and \overline{RD} inputs, an output is applied to the DB0 through DB7 outputs and the interrupt flip-flop is reset. When either the \overline{CS} or \overline{RD} inputs return to a high state, the DB0 through DB7 outputs are disabled (returned to the high-impedance state). The interrupt flip-flop remains reset.

description

The ADC0804 is a CMOS 8-bit successive-approximation analog-to-digital converter that uses a modified potentiometric (256R) ladder. The ADC0804 is designed to operate from common microprocessor control buses, with the three-state output latches driving the data bus. The ADC0804 can be made to appear to the microprocessor as a memory location or an I/O port. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

A differential analog voltage input allows increased common-mode rejection and offset of the zero-input analog voltage value. Although a reference input (REF/2) is available to allow 8-bit conversion over smaller analog voltage spans or to make use of an external reference, ratiometric conversion is possible with the REF/2 input open. Without an external reference, the conversion takes place over a span from V_{CC} to analog ground (ANLG GND). The ADC0804 can operate with an external clock signal or, with an additional resistor and capacitor, can operate using an on-chip clock generator.

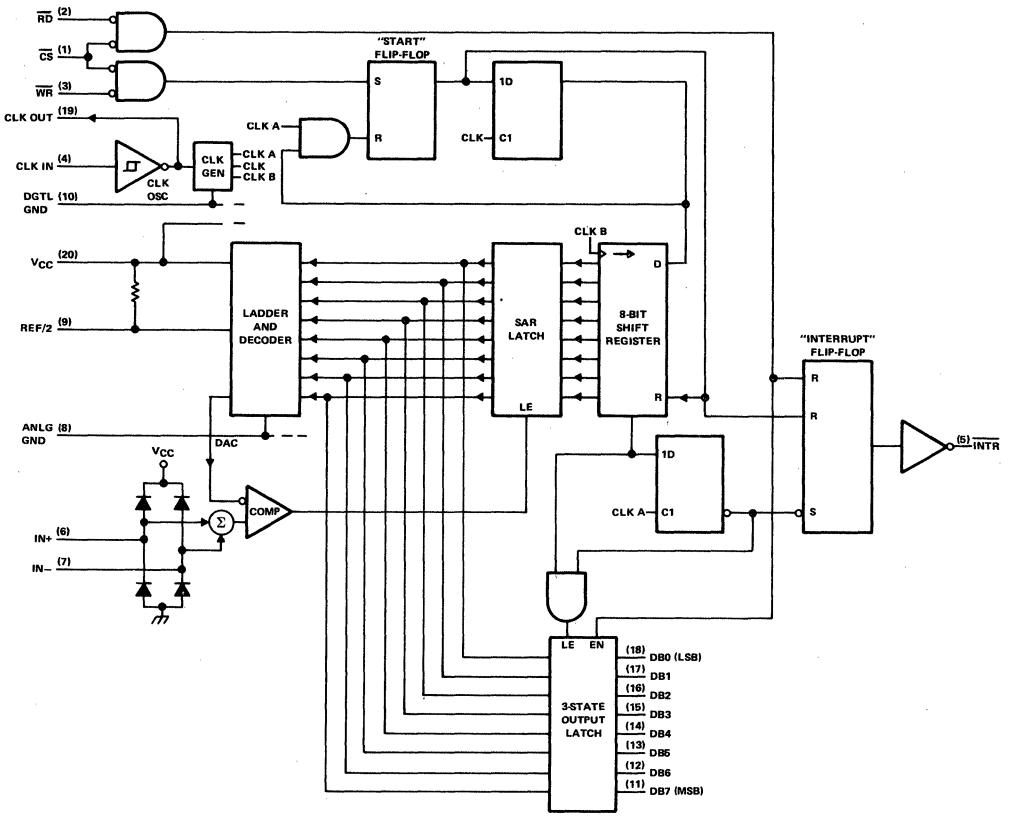

The ADC0804I is characterized for operation from -40°C to 85°C. The ADC0804C is characterized for operation from 0°C to 70°C.

Data Acquisition Circuits

The ADC0804 contains a circuit equivalent to a 256-resistor network. Analog switches are sequenced by successive approximation logic to match an analog differential input voltage ($V_{IN+} - V_{IN-}$) to a corresponding tap on the 256-resistor network. The most-significant bit (MSB) is tested first. After eight comparisons (64 clock periods), an eight-bit binary code (1111 1111 = full scale) is transferred to an output latch and the interrupt (\overline{INTR}) output goes low. The device can be operated in a free-running mode by connecting the \overline{INTR} output to the write (\overline{WR}) input and holding the conversion start (\overline{CS}) input at a low level. To ensure start-up under all conditions, a low-level \overline{WR} input is required during the power-up cycle. Taking \overline{CS} low anytime after that will interrupt a conversion in process.

When the \overline{WR} input goes low, the ADC0804 successive approximation register (SAR) and eight-bit shift register are reset. As long as both \overline{CS} and \overline{WR} remain low, the ADC0804 will remain in a reset state. One to eight clock periods after \overline{CS} or \overline{WR} makes a low-to-high transition, conversion starts.

When the \overline{CS} and \overline{WR} inputs are low, the start flip-flop is set and the interrupt flip-flop and eight-bit register are reset. The next clock pulse transfers a logic high to the output of the start flip-flop. The logic high is ANDed with the next clock pulse placing a logic high on the reset input of the start flip-flop. If either \overline{CS} or \overline{WR} have gone high, the set signal to the start flip-flop is removed causing it to be reset. A logic high is placed on the D input of the eight-bit shift register and the conversion process is started. If the \overline{CS} and \overline{WR} inputs are still low, the start flip-flop, the eight-bit shift register, and the SAR remain reset. This action allows for wide \overline{CS} and \overline{WR} inputs with conversion starting from one to eight clock periods after one of the inputs goes high.

When the logic high input has been clocked through the eight-bit shift register, completing the SAR search, it is applied to an AND gate controlling the output latches and to the D input of a flip-flop. On the next clock pulse, the digital word is transferred to the three-state output latches and the interrupt flip-flop is set. The output of the interrupt flip-flop is inverted to provide an \overline{INTR} output that is high during conversion and low when the conversion is completed.

When a low is at both the \overline{CS} and \overline{RD} inputs, an output is applied to the DB0 through DB7 outputs and the interrupt flip-flop is reset. When either the \overline{CS} or \overline{RD} inputs return to a high state, the DB0 through DB7 outputs are disabled (returned to the high-impedance state). The interrupt flip-flop remains reset.

ADC0808, ADC0809 CMOS ANALOG-TO-DIGITAL CONVERTERS WITH 8-CHANNEL MULTIPLEXERS

D2642, JUNE 1981—REVISED FEBRUARY 1986

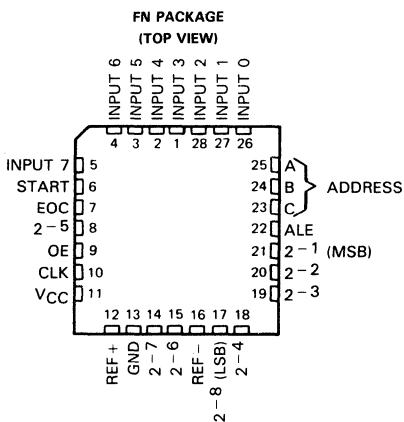

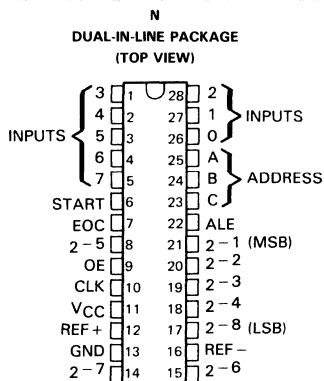

- Total Unadjusted Error . . . ± 0.75 LSB Max for ADC0808 and ± 1.25 LSB Max for ADC0809
- Resolution of 8 Bits
- 100 μ s Conversion Time
- Ratiometric Conversion
- Guaranteed Monotonicity
- No Missing Codes
- Easy Interface with Microprocessors
- Latched 3-State Outputs
- Latched Address Inputs
- Single 5-Volt Supply
- Low Power Consumption
- Designed to be Interchangeable with National Semiconductor ADC0808, ADC0809

description

The ADC0808 and ADC0809 are monolithic CMOS devices with an 8-channel multiplexer, an 8-bit analog-to-digital (A/D) converter, and microprocessor-compatible control logic. The 8-channel multiplexer can be controlled by a microprocessor through a 3-bit address decoder with address load to select any one of eight single-ended analog switches connected directly to the comparator. The 8-bit A/D converter uses the successive-approximation conversion technique featuring a high-impedance threshold detector, a switched-capacitor array, a sample-and-hold, and a successive-approximation register (SAR). Detailed information on interfacing to most popular microprocessors is readily available from the factory.

The comparison and converting methods used eliminate the possibility of missing codes, nonmonotonicity, and the need for zero or full-scale adjustment. Also featured are latched 3-state outputs from the SAR and latched inputs to the multiplexer address decoder. The single 5-volt supply and low power requirements make the ADC0808 and ADC0809 especially useful for a wide variety of applications. Ratiometric conversion is made possible by access to the reference voltage input terminals.

The ADC0808 and ADC0809 are characterized for operation from -40°C to 85°C .

†Typical values for all except supply voltage sensitivity are at $V_{CC} = 5\text{ V}$, and all are at $T_A = 25^\circ\text{C}$.

- NOTES:
- Supply voltage sensitivity relates to the ability of an analog-to-digital converter to maintain accuracy as the supply voltage varies. The supply and $V_{\text{ref}+}$ are varied together and the change in accuracy is measured with respect to full-scale.
 - Linearity error is the maximum deviation from a straight line through the end points of the A/D transfer characteristic.
 - Zero error is the difference between 00000000 and the converted output for zero input voltage; full-scale error is the difference between 11111111 and the converted output for full-scale input voltage.
 - Total unadjusted error is the maximum sum of linearity error, zero error, and full-scale error.
 - Refer to the operating sequence diagram.
 - For clock frequencies other than 640 kHz, t_{d(EOC)} maximum is 8 clock periods plus 2 μs.

PRINCIPLES OF OPERATION

The ADC0808 and ADC0809 each consists of an analog signal multiplexer, an 8-bit successive-approximation converter, and related control and output circuitry.

multiplexer

The analog multiplexer selects 1 of 8 single-ended input channels as determined by the address decoder. Address load control loads the address code into the decoder on a low-to-high transition. The output latch is reset by the positive-going edge of the start pulse. Sampling also starts with the positive-going edge of the start pulse and lasts for 32 clock periods. The conversion process may be interrupted by a new start pulse before the end of 64 clock periods. The previous data will be lost if a new start of conversion occurs before the 64th clock pulse. Continuous conversion may be accomplished by connecting the End-of-Conversion output to the start input. If used in this mode an external pulse should be applied after power up to assure start up.

converter

The CMOS threshold detector in the successive-approximation conversion system determines each bit by examining the charge on a series of binary-weighted capacitors (Figure 1). In the first phase of the conversion process, the analog input is sampled by closing switch S_C and all S_T switches, and by simultaneously charging all the capacitors to the input voltage.

In the next phase of the conversion process, all S_T and S_C switches are opened and the threshold detector begins identifying bits by identifying the charge (voltage) on each capacitor relative to the reference voltage. In the switching sequence, all eight capacitors are examined separately until all 8 bits are identified, and then the charge-convert sequence is repeated. In the first step of the conversion phase, the threshold detector looks at the first capacitor (weight = 128). Node 128 of this capacitor is switched to the reference voltage, and the equivalent nodes of all the other capacitors on the ladder are switched to REF-. If the voltage at the summing node is greater than the trip-point of the threshold detector (approximately one-half the V_{CC} voltage), a bit is placed in the output register, and the 128-weight capacitor is switched to REF-. If the voltage at the summing node is less than the trip point of the threshold detector, this 128-weight capacitor remains connected to REF+ through the remainder of the capacitor-sampling (bit-counting) process. The process is repeated for the 64-weight capacitor, the 32-weight capacitor, and so forth down the line, until all bits are counted.

With each step of the capacitor-sampling process, the initial charge is redistributed among the capacitors. The conversion process is successive approximation, but relies on charge redistribution rather than a successive-approximation register (and reference DAC) to count and weigh the bits from MSB to LSB.

- No Missing Codes
- Easy Interface with Microprocessors
- Latched 3-State Outputs
- Latched Address Inputs
- Single 5-Volt Supply
- Low Power Consumption
- Designed to be Interchangeable with National Semiconductor ADC0808CJ

description

The ADC0808M is a monolithic CMOS device with an 8-channel multiplexer, an 8-bit analog-to-digital (A/D) converter, and microprocessor-compatible control logic. The 8-channel multiplexer can be controlled by a microprocessor through a 3-bit address decoder with address load to select any one of eight single-ended analog switches connected directly to the comparator. The 8-bit A/D converter uses the successive-approximation conversion technique featuring a high-impedance threshold detector, a switched capacitor array, a sample-and-hold, and a successive-approximation register (SAR). Detailed information on interfacing to most popular microprocessors is readily available from the factory.

The comparison and converting methods used eliminate the possibility of missing codes, nonmonotonicity, and the need for zero or full-scale adjustment. Also featured are latched 3-state outputs from the SAR and latched inputs to the multiplexer address decoder. The single 5-volt supply and low power requirements make the ADC0808M especially useful for a wide variety of applications. Ratiometric conversion is made possible by access to the reference voltage input terminals.

The ADC0808M is characterized for operation over the full military temperature range of -55°C to 125°C .

8. Refer to the operating sequence diagram.
9. For clock frequencies other than 640 kHz, t_{conv} is 57 clock cycles minimum and 74 clock cycles maximum.
10. For clock frequencies other than 640 kHz, $t_{\text{D(EOC)}}$ maximum is 8 clock cycles plus 2 μs .

PARAMETER MEASUREMENT INFORMATION

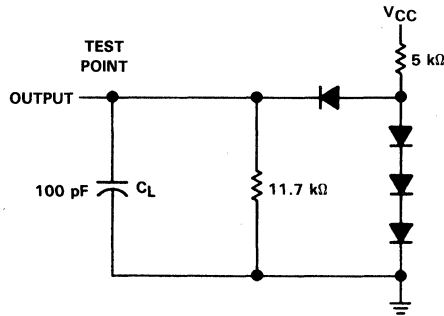

FIGURE 1. TEST CIRCUIT

PRINCIPLES OF OPERATION

The ADC0808M consists of an analog signal multiplexer, an 8-bit successive-approximation converter, and related control and output circuitry.

2

Data Acquisition Circuits

multiplexer

The analog multiplexer selects 1 of 8 single-ended input channels as determined by the address decoder. Address load control loads the address code into the decoder on a low-to-high transition. The output latch is reset by the positive-going edge of the start pulse. Sampling also starts with the positive-going edge of the start pulse and lasts for 32 clock periods. The conversion process may be interrupted by a new start pulse before the end of 64 clock periods. The previous data will be lost if a new start of conversion occurs before the 64th clock pulse. Continuous conversion may be accomplished by connecting the End-of-Conversion output to the start input. If used in this mode an external pulse should be applied after power up to assure start up.

converter

The CMOS threshold detector in the successive-approximation conversion system determines each bit by examining the charge on a series of binary-weighted capacitors (Figure 2). In the first phase of the conversion process, the analog input is sampled by closing switch S_C and all S_T switches, and by simultaneously charging all the capacitors to the input voltage.

In the next phase of the conversion process, all S_T and S_C switches are opened and the threshold detector begins identifying bits by identifying the charge (voltage) on each capacitor relative to the reference voltage. In the switching sequence, all eight capacitors are examined separately until all 8 bits are identified, and then the charge-convert sequence is repeated. In the first step of the conversion phase, the threshold detector looks at the first capacitor (weight = 128). Node 128 of this capacitor is switched to the reference voltage, and the equivalent nodes of all the other capacitors on the ladder are switched to REF-. If the voltage at the summing node is greater than the trip-point of the threshold detector (approximately one-half the V_{CC} voltage), a bit is placed in the output register, and the 128-weight capacitor is switched to REF-. If the voltage at the summing node is less than the trip point of the threshold detector, this 128-weight capacitor remains connected to REF+ through the remainder of the capacitor-sampling (bit-counting) process. The process is repeated for the 64-weight capacitor, the 32-weight capacitor, and so forth down the line, until all bits are counted.

With each step of the capacitor-sampling process, the initial charge is redistributed among the capacitors. The conversion process is successive approximation, but relies on charge redistribution rather than a successive-approximation register (and reference DAC) to count and weigh the bits from MSB to LSB.

description

These devices are 8-bit successive-approximation analog-to-digital converters. The ADC0831A and ADC0831B have single input channels; the ADC0832A and ADC0832B have multiplexed twin input channels. The serial output is configured to interface with standard shift registers or microprocessors. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

The ADC0832 multiplexer is software configured for single-ended or differential inputs. The differential analog voltage input allows for common-mode rejection or offset of the analog zero input voltage value. In addition, the voltage reference input can be adjusted to allow encoding any smaller analog voltage span to the full 8 bits of resolution.

The operation of the ADC0831 and ADC0832 devices is very similar to the more complex ADC0834 and ADC0838 devices. Ratiometric conversion can be attained by setting the REF input equal to the maximum analog input signal value, which gives the highest possible conversion resolution. Typically, REF is set equal to V_{CC} (done internally on the ADC0832). For more detail on the operation of the ADC0831 and ADC0832 devices, refer to the ADC0834/ADC0838 data sheet.

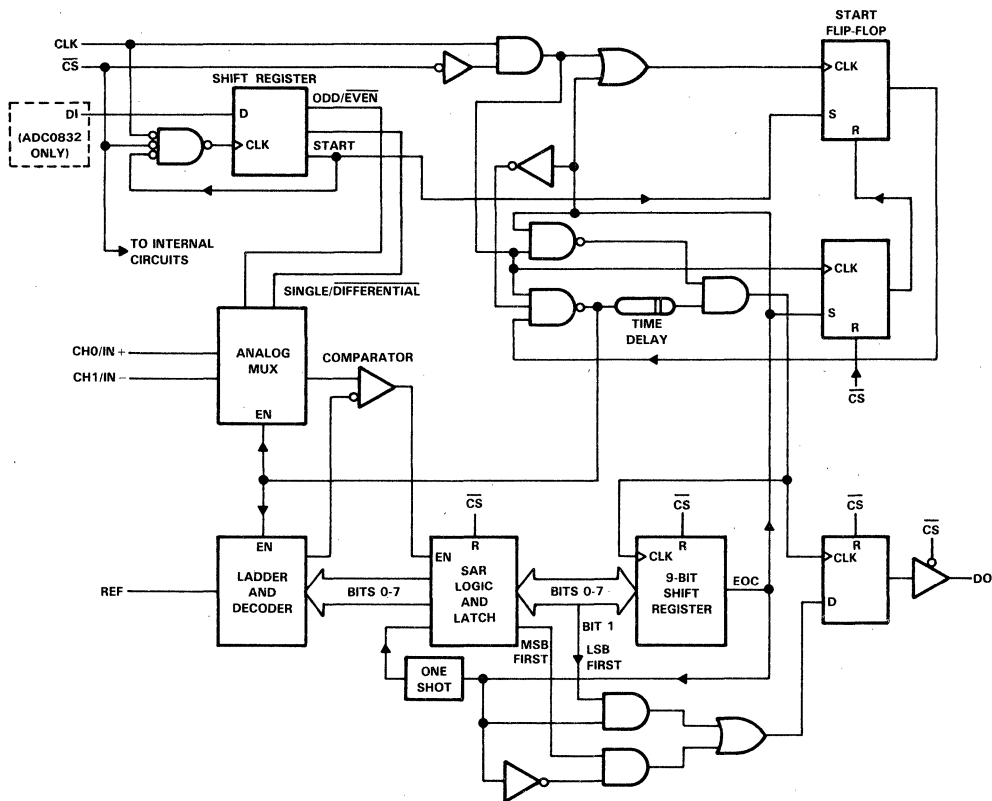

The ADC0831AI, ADC0831BI, ADC0832AI, and ADC0832BI are characterized for operation from -40°C to 85°C . The ADC0831AC, ADC0831BC, ADC0832AC, and ADC0832BC are characterized for operation from 0°C to 70°C .

† All parameters are measured under open-loop conditions with zero common-mode input voltage.

‡ All typical values are at $V_{CC} = 5\text{ V}$, $T_A = 25^\circ\text{C}$.

NOTES: 3. If channel IN^- is more positive than channel IN^+ , the digital output code will be 0000 0000. Connected to each analog input are two on-chip diodes that will conduct forward current for analog input voltages one diode drop above V_{CC} . Care must be taken during testing at low V_{CC} levels (4.5 V) because high-level analog input voltage (5 V) can, especially at high temperatures, cause this input diode to conduct and cause errors for analog inputs that are near full-scale. As long as the analog voltage does not exceed the supply voltage by more than 50 mV, the output code will be correct. To achieve an absolute 0 V to 5 V input voltage range requires a minimum V_{CC} of 4.95 volts for all variations of temperature and load.

4. Standby input currents are currents going into or out of the on or off channels when the A/D converter is not performing conversion and the clock is in a high or low steady-state condition.

operating characteristics $V_{CC} = \text{REF} = 5\text{ V}$, $f_{clock} = 250\text{ kHz}$, $t_r = t_f = 20\text{ ns}$, $T_A = 25^\circ\text{C}$ (unless otherwise noted)

PARAMETER	TEST CONDITIONS†	BI, BC SUFFIX			AI, AC SUFFIX			UNIT
		MIN	TYP	MAX	MIN	TYP	MAX	
Supply-voltage variation error	$V_{CC} = 4.75\text{ V}$ to 5.25 V	$\pm 1/16$	$\pm 1/4$		$\pm 1/16$	$\pm 1/4$		LSB
Total unadjusted error (see Note 5)	$V_{ref} = 5\text{ V}$, $T_A = \text{MIN}$ to MAX		$\pm 1/2$			± 1		LSB
Common-mode error	Differential mode	$\pm 1/16$	$\pm 1/4$		$\pm 1/16$	$\pm 1/4$		LSB

		$C_L = 100\text{ pF}$, $R_L = 2\text{ k}\Omega$	500		500			
t_{conv}	Conversion time (multiplexer addressing time not included)		8		8		clock periods	

† All parameters are measured under open-loop conditions with zero common-mode input voltage. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions.

NOTES: 5. Total unadjusted error includes offset, full-scale, linearity, and multiplexer errors.

6. The most significant-bit-first data is output directly from the comparator and therefore requires additional delay to allow for comparator response time. Least-significant-bit-first data applies only to ADC0832.

ADC0834A, ADC0838A, ADC0834B, ADC0838B A/D PERIPHERALS WITH SERIAL CONTROL

D2795, AUGUST 1985—REVISED OCTOBER 1986

- 8-Bit Resolution
- Easy Interface to Microprocessors or Stand-Alone Operation
- Operates Ratiometrically or with 5-V Reference
- 4- or 8-Channel Multiplexer Options with Address Logic
- Shunt Regulator Allows Operation with High-Voltage Supplies
- Input Range 0 to 5 V with Single 5-V Supply
- Remote Operation with Serial Data Link
- Inputs and Outputs are Compatible with TTL and MOS
- Conversion Time of 32 μ s at $f_{clock} = 250$ kHz
- Designed to be Interchangeable with National Semiconductor ADC0834 and ADC0838

DEVICE	TOTAL UNADJUSTED ERROR	
	A SUFFIX	B SUFFIX
ADC0834	± 1 LSB	$\pm 1/2$ LSB
ADC0838	± 1 LSB	$\pm 1/2$ LSB

description

These devices are 8-bit successive-approximation analog-to-digital converters each with an input-configurable multichannel multiplexer and serial input/output. The serial input/output is configured to interface with standard shift registers or microprocessors. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

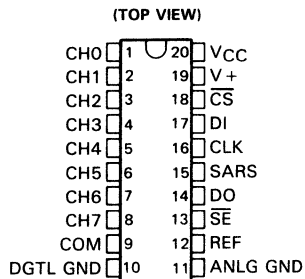

The ADC0834 (4-channel) and ADC0838 (8-channel) multiplexer is software configured for single-ended or differential inputs as well as pseudo-differential input assignments. The differential analog voltage input allows for common-mode rejection or offset of the analog zero input voltage value. In addition, the voltage reference input can be adjusted to allow encoding any smaller analog voltage span to the full 8 bits of resolution.

The ADC0834AI, ADC0834BI, ADC0838AI, and ADC0838BI are characterized for operation from -40°C to 85°C . The ADC0834AC, ADC0834BC, ADC0838AC, and ADC0838BC are characterized for operation from 0°C to 70°C .

functional block diagram

NOTE A: For the ADC0834, D1 is input directly to the D input of SELECT 1, SELECT 0 is forced to a high.

functional description

The ADC0834 and ADC0838 use a sample data comparator structure that converts differential analog inputs by a successive-approximation routine. Operation of both devices is similar with the exception of a select enable (\overline{SE}) input, analog common input, and multiplexer addressing. The input voltage to be converted is applied to a channel terminal and is compared to ground (single-ended), to an adjacent input (differential), or to a common terminal (pseudo-differential) that can be an arbitrary voltage. The input terminals are assigned a positive (+) or negative (-) polarity. If the signal inputs applied to the assigned positive terminal is less than the signal on the negative terminal, the converter output is all zeros.

Channel selection and input configuration are under software control using a serial data link from the controlling processor. A serial communication format allows more functions to be included in a converter package with no increase in size. In addition, it eliminates the transmission of low-level analog signals by locating the converter at the analog sensor and communicating serially with the controlling processor. This process returns noise-free digital data to the processor.

A particular input configuration is assigned during the multiplexer addressing sequence. The multiplexer address is shifted into the converter through the data input (DI) line. The multiplexer address selects the analog inputs to be enabled and determines whether the input is single-ended or differential. When the input is differential, the polarity of the channel input is assigned. Differential inputs are assigned to adjacent channel pairs. For example, channel 0 and channel 1 may be selected as a differential pair. These channels cannot act differentially with any other channel. In addition to selecting the differential mode, the polarity may also be selected. Either channel of the channel pair may be designated as the negative or positive input.

The common input on the ADC0838 can be used for a pseudo-differential input. In this mode, the voltage on the common input is considered to be the negative differential input for all channel inputs. This voltage can be any reference potential common to all channel inputs. Each channel input can then be selected as the positive differential input. This feature is useful when all analog circuits are biased to a potential other than ground.

A conversion is initiated by setting the chip select (\overline{CS}) input low. This enables all logic circuits. The \overline{CS} input must be held low for the complete conversion process. A clock input is received from the processor. On each low-to-high transition of the clock input, the data on the DI input is clocked into the multiplexer address shift register. The first logic high on the input is the start bit. A 3- to 4-bit assignment word follows the start bit. On each successive low-to-high transition of the clock input, the start bit and assignment word are shifted through the shift register. When the start bit has been shifted into the start location of the multiplexer register, the input channel has been selected and conversion starts. The SAR Status output (SARS) goes high to indicate that a conversion is in progress and the DI input to the multiplexer shift register is disabled for the duration of the conversion.

An interval of one clock period is automatically inserted to allow for the selected multiplexed channel to settle. The data output DO comes out of the high-impedance state and provides a leading low for this one clock period of multiplexer settling time. The SAR comparator compares successive outputs from the resistive ladder with the incoming analog signal. The comparator output indicates whether the analog input is greater than or less than the resistive ladder output. As the conversion proceeds, conversion data is simultaneously output from the DO output pin with the most significant bit (MSB) first.

After eight clock periods the conversion is complete and the SAR Status (SARS) output goes low.

The ADC0834 outputs the least-significant-bit-first data after the MSB-first data stream. If the shift enable (\overline{SE}) line is held high on the ADC0838, the value of the least significant bit (LSB) will remain on the data line. When \overline{SE} is forced low, the data is then clocked out as LSB-first data. (To output LSB first, the \overline{SE} control input must first go low, then the data stored in the 9-bit shift register will output with LSB first.) When \overline{CS} goes high, all internal registers are cleared. At this time the output circuits go to the high-impedance state. If another conversion is desired, the \overline{CS} line must make a high-to-low transition followed by address information.

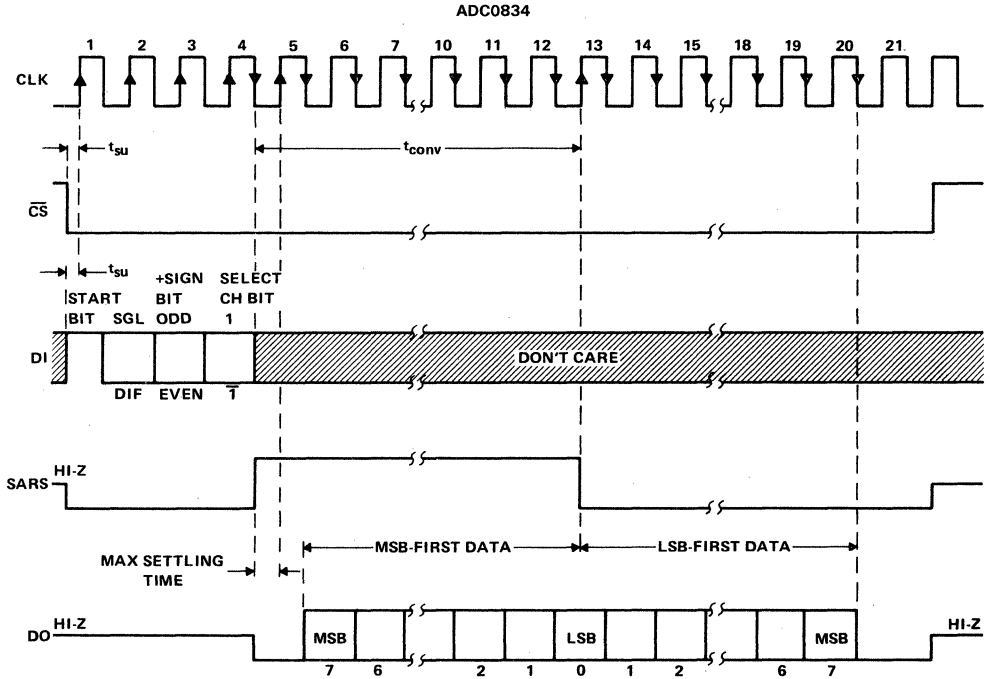

ADC0834A, ADC0838A, ADC0834B, ADC0838B A/D PERIPHERALS WITH SERIAL CONTROL

functional description (continued)

The DI and DO pins can be tied together and controlled by a bidirectional processor I/O bit received on a single wire. This is possible because the DI input is only examined during the multiplexer addressing interval and the DO output is still in a high-impedance state.

Detailed information on interfacing to most popular microprocessors is readily available from the factory.

absolute maximum ratings over recommended operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC} (see Notes 1 and 2)	6.5 V
Input voltage range: Logic	-0.3 V to 15 V
Analog	-0.3 V to $V_{CC} + 0.3$ V
Input current: V+ input	15 mA
Any other input	± 5 mA
Total input current for package	± 20 mA
Operating free-air temperature range: AI and BI suffixes	-40°C to 85°C
AC and BC suffixes	0°C to 70°C
Storage temperature range	-65°C to 150°C
Case temperature for 10 seconds: FN package	260°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: N package	260°C

- NOTES: 1. All voltage values, except differential voltages, are with respect to the network ground terminal.
 2. Internal zener diodes are connected from the V_{CC} input to ground and from the V+ input to ground. The breakdown voltage of each zener diode is approximately 7 volts. One zener diode can be used as a shunt regulator and connects to V_{CC} through a regular diode. When the voltage regulator powers the converter, this zener and regular diode combination ensures that the V_{CC} input (6.4 V) is less than the zener breakdown voltage. A series resistor is recommended to limit current into the V+ input.

total device

PARAMETER		TEST CONDITIONS†	MIN	TYP‡	MAX	UNIT
V_{Z}	Internal zener diode breakdown voltage	$I_{\text{I}} = 15\text{ mA}$ at $V+$ pin, See Note 2	6.3	7	8.5	V
I_{CC}	Supply current			1	2.5	mA

†All parameters are measured under open-loop conditions with zero common-mode input voltage.

‡All typical values are at $V_{CC} = 5\text{ V}$, $V+ = 5\text{ V}$, $T_{\text{A}} = 25^{\circ}\text{C}$.

NOTES: 2. Internal zener diodes are connected from the V_{CC} input to ground and from the $V+$ input to ground. The breakdown voltage of each zener diode is approximately 7 volts. One zener diode can be used as a shunt regulator and connects to V_{CC} through a regular diode. When the voltage regulator powers the converter, this zener and regular diode combination ensures that the V_{CC} input (6.4 V) is less than the zener breakdown voltage. A series resistor is recommended to limit current into the $V+$ input.

4. If channel $\text{IN}-$ is more positive than channel $\text{IN}+$, the digital output code will be 0000 0000. Connected to each analog input are two on-chip diodes that will conduct forward current for analog input voltages one diode drop above V_{CC} . Care must be taken during testing at low V_{CC} levels (4.5 V) because high-level analog input voltage (5 V) can, especially at high temperatures, cause this input diode to conduct and cause errors for analog inputs that are near full-scale. As long as the analog voltage does not exceed the supply voltage by more than 50 mV, the output code will be correct. To achieve an absolute 0 V to 5 V input voltage range requires a minimum V_{CC} of 4.950 volts for all variations of temperature and load.

5. Standby input currents are currents going into or out of the on or off channels when the A/D converter is not performing conversion and the clock is in a high or low steady-state condition.

TL0808, TL0809 LOW-POWER CMOS ANALOG-TO-DIGITAL CONVERTERS WITH 8-CHANNEL MULTIPLEXERS

D2642, FEBRUARY 1986 — REVISED SEPTEMBER 1986

- Total Unadjusted Error . . . ± 0.75 LSB Max for TL0808 and ± 1.25 LSB Max for TL0809 Over Temperature Range
- Ideal for Battery Operated, Portable Instrumentation Applications
- Resolution of 8 Bits
- 100 μ s Conversion Time
- Ratiometric Conversion
- Guaranteed Monotonicity
- No Missing Codes
- Easy Interface with Microprocessors
- Latched 3-State Outputs
- Latched Address Inputs
- Single 5-Volt Supply
- Extremely Low Power Consumption . . . 0.3 mW Typ
- Improved Direct Replacements for ADC0808, ADC0809

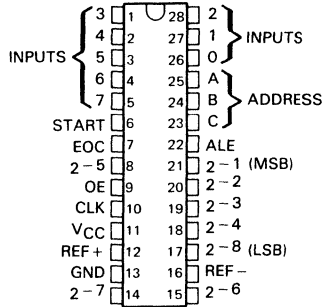

description

The TL0808 and TL0809 are monolithic CMOS devices with an 8-channel multiplexer, an 8-bit analog-to-digital (A/D) converter, and microprocessor-compatible control logic. The 8-channel multiplexer can be controlled by a microprocessor through a 3-bit address decoder with address load to select any one of eight single-ended analog switches connected directly to the comparator. The 8-bit A/D converter uses the successive-approximation conversion technique featuring a high-impedance threshold detector, a switched-capacitor array, a sample-and-hold, and a successive-approximation register (SAR). Detailed information on interfacing to most popular microprocessors is readily available from the factory. These devices are designed to operate from common microprocessor control buses, with three-state output latches driving the data bus. The devices can be made to appear to the microprocessor as a memory location or an I/O port.

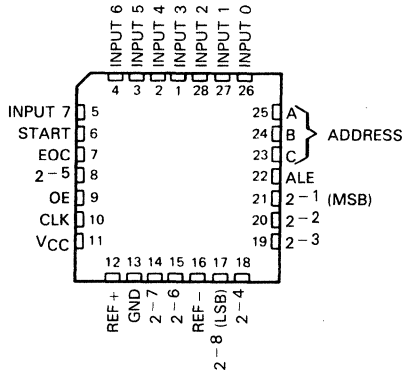

The comparison and converting methods used eliminate the possibility of missing codes, nonmonotonicity, and the need for zero or full-scale adjustment. Also featured are latched 3-state outputs from the SAR and latched inputs to the multiplexer address decoder. The single 3-volt supply and extremely low power requirements make the TL0808 and TL0809 especially useful for a wide variety of applications including portable battery and LCD applications. Ratiometric conversion is made possible by access to the reference voltage input terminals.

The TL0808 and TL0809 are characterized for operation from -40°C to 85°C .

t_{conv} Conversion time	See Note 10	90	100	116	90	110	116	μs
Delay time, $t_d(\text{EOC})$ end of conversion output	See Notes 10 and 11	0		14.5	0		14.5	μs

†Typical values for all except supply voltage sensitivity are at $V_{CC} = 3\text{ V}$, and all are at $T_A = 25^\circ\text{C}$.

- NOTES:
- Supply voltage sensitivity relates to the ability of an analog-to-digital converter to maintain accuracy as the supply voltage varies. The supply and V_{ref+} are varied together and the change in accuracy is measured with respect to full-scale.
 - Linearity error is the maximum deviation from a straight line through the end points of the A/D transfer characteristic.
 - Zero error is the difference between 00000000 and the converted output for zero input voltage; full-scale error is the difference between 11111111 and the converted output for full-scale input voltage.
 - Total unadjusted error is the maximum sum of linearity error, zero error, and full-scale error.
 - Refer to the operating sequence diagram.
 - For clock frequencies other than 640 kHz, $t_d(\text{EOC})$ maximum is 8 clock periods plus 2 μs .

TL0808, TL0809

LOW-POWER CMOS ANALOG-TO-DIGITAL CONVERTERS WITH 8-CHANNEL MULTIPLEXERS

PRINCIPLES OF OPERATION

The TL0808 and TL0809 each consists of an analog signal multiplexer, an 8-bit successive-approximation converter, and related control and output circuitry.

2

Data Acquisition Circuits

multiplexer

The analog multiplexer selects 1 of 8 single-ended input channels as determined by the address decoder. Address load control loads the address code into the decoder on a low-to-high transition. The output latch is reset by the positive-going edge of the start pulse. Sampling also starts with the positive-going edge of the start pulse and lasts for 32 clock periods. The conversion process may be interrupted by a new start pulse before the end of 64 clock periods. The previous data will be lost if a new start of conversion occurs before the 64th clock pulse. Continuous conversion may be accomplished by connecting the End-of-Conversion output to the start input. If used in this mode an external pulse should be applied after power up to assure start up.

converter

The CMOS threshold detector in the successive-approximation conversion system determines each bit by examining the charge on a series of binary-weighted capacitors (Figure 1). In the first phase of the conversion process, the analog input is sampled by closing switch S_C and all S_T switches, and by simultaneously charging all the capacitors to the input voltage.

In the next phase of the conversion process, all S_T and S_C switches are opened and the threshold detector begins identifying bits by identifying the charge (voltage) on each capacitor relative to the reference voltage. In the switching sequence, all eight capacitors are examined separately until all 8 bits are identified, and then the charge-convert sequence is repeated. In the first step of the conversion phase, the threshold detector looks at the first capacitor (weight = 128). Node 128 of this capacitor is switched to the reference voltage, and the equivalent nodes of all the other capacitors on the ladder are switched to REF-. If the voltage at the summing node is greater than the trip-point of the threshold detector (approximately one-half the V_{CC} voltage), a bit is placed in the output register, and the 128-weight capacitor is switched to REF-. If the voltage at the summing node is less than the trip point of the threshold detector, this 128-weight capacitor remains connected to REF+ through the remainder of the capacitor-sampling (bit-counting) process. The process is repeated for the 64-weight capacitor, the 32-weight capacitor, and so forth down the line, until all bits are counted.

With each step of the capacitor-sampling process, the initial charge is redistributed among the capacitors. The conversion process is successive approximation, but relies on charge redistribution rather than a successive-approximation register (and reference DAC) to count and weigh the bits from MSB to LSB.

Data Acquisition Circuits

description

The TL182, TL185, TL188, and TL191 are monolithic high-speed analog switches using BI-MOS technology. They comprise JFET-input buffers, level translators, and output JFET switches. The TL182 switches are SPST; the TL185 switches are SPDT. The TL188 is a pair of complementary SPST switches as is each half of the TL191.

A high level at a control input of the TL182 turns the associated switch off. A high level at a control input of the TL185 turns the associated switch on. For the TL188, a high level at the control input turns the associated switches S1 on and S2 off.

The threshold of the input buffer is determined by the voltage applied to the reference input (V_{ref}). The input threshold is related to the reference input by the equation $V_{th} = V_{ref} + 1.4\text{ V}$. Thus, for TTL compatibility, the V_{ref} input is connected to ground. The JFET input makes the device compatible with bipolar, MOD, and CMOS logic families. Threshold compatibility may, again, be determined by $V_{th} = V_{ref} + 1.4\text{ V}$.

The output switches are junction field-effect transistors featuring low on-state resistance and high off-state resistance. The monolithic structure ensures uniform matching.

BI-MOS technology is a major breakthrough in linear integrated circuit processing. BI-MOS can have ion-implanted JFETs, p-channel MOS-FETs, plus the usual bipolar components all on the same chip. BI-MOS allows circuit designs that previously have been available only as expensive hybrids to be monolithic.

Devices with an "M" suffix are characterized for operation from -55°C to 125°C , those with an "I" suffix are characterized for operation from -25°C to 85°C , and those with a "C" suffix are characterized for operation from 0°C to 70°C .

TL500C/TL501C ANALOG PROCESSORS

- True Differential Inputs
- Automatic Zero
- Automatic Polarity
- High Input Impedance . . . 10^9 Ohms Typically

TL500C CAPABILITIES

- Resolution . . . 14 Bits (with TL502C)
- Linearity Error . . . 0.001%
- 4 1/2-Digit Readout Accuracy with External Precision Reference

TL502C/TL503C DIGITAL PROCESSORS

- Fast Display Scan Rates
- Internal Oscillator May Be Driven or Free-Running
- Interdigit Blanking
- Over-Range Blanking
- 4 1/2-Digit Display Circuitry
- High-Sink-Current Digit Driver for Large Displays

TL501C CAPABILITIES

- Resolution . . . 10-13 Bits (with TL502C)
- Linearity Error . . . 0.01%
- 3 1/2-Digit Readout Accuracy

TL502C CAPABILITIES

- Compatible with Popular Seven-Segment Common-Anode Displays
- High-Sink-Current Segment Driver for Large Displays

TL503C CAPABILITIES

- Multiplexed BCD Outputs
- High-Sink-Current BCD Outputs

Caution. These devices have limited built-in gate protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

description

The TL500C and TL501C analog processors and TL502C and TL503C digital processors provide the basic functions for a dual-slope-integrating analog-to-digital converter.

The TL500C and TL501C contain the necessary analog switches and decoding circuits, reference voltage generator, buffer, integrator, and comparator. These devices may be controlled by the TL502C, TL503C, by discrete logic, or by a software routine in a microprocessor.

The TL502C and TL503C each includes oscillator, counter, control logic, and digit enable circuits. The TL502C provides multiplexed outputs for seven-segment displays, while the TL503C has multiplexed BCD outputs.

When used in complementary fashion, these devices form a system that features automatic zero-offset compensation, true differential inputs, high input impedance, and capability for 4 1/2-digit accuracy. Applications include the conversion of analog data from high-impedance sensors of pressure, temperature, light, moisture, and position. Analog-to-digital-logic conversion provides display and control signals for weight scales, industrial controllers, thermometers, light-level indicators, and many other applications.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

Data Acquisition Circuits

principles of operation

The basic principle of dual-slope-integrating converters is relatively simple. A capacitor, C_X , is charged through the integrator from V_{CT} for a fixed period of time at a rate determined by the value of the unknown voltage input. Then the capacitor is discharged at a fixed rate (determined by the reference voltage) back to V_{CT} where the discharge time is measured precisely. The relationship of the charge and discharge values are shown below (see Figure 1).

$$V_{CX} = V_{CT} - \frac{V_I t_1}{R_X C_X} \quad \text{Charge} \quad (1)$$

$$V_{CT} = V_{CX} - \frac{V_{ref} t_2}{R_X C_X} \quad \text{Discharge} \quad (2)$$

Combining equations 1 and 2 results in:

$$\frac{V_I}{V_{ref}} = \frac{t_2}{t_1} \quad (3)$$

where:

- V_{CT} = Comparator (offset) threshold voltage
- V_{CX} = Voltage change across C_X during t_1 and during t_2 (equal in magnitude)
- V_I = Average value of input voltage during t_1
- t_1 = Time period over which unknown voltage is integrated
- t_2 = Unknown time period over which a known reference voltage is integrated.

Equation (3) illustrates the major advantages of a dual-slop converter:

- a. Accuracy is not dependent on absolute values of t_1 and t_2 , but is dependent on their ratios. Long-term clock frequency variations will not affect the accuracy.
- b. Offset values, V_{CT} , are not important.

The BCD counter in the digital processor (see Figure 2) and the control logic divide each measurement cycle into three phases. The BCD counter changes at a rate equal to one-half the oscillator frequency.

auto-zero phase

The cycle begins at the end of the integrate-reference phase when the digital processor applies low levels to inputs A and B of the analog processor. If the trigger input is at a high level, a free-running condition exists and continuous conversions are made. However, if the trigger input is low, the digital processor stops the counter at 20,000, entering a hold mode. In this mode, the processor samples the trigger input every 4000 oscillator pulses until a high level is detected. When this occurs, the counter is started again and is carried to completion at 30,000. The reference voltage is stored on reference capacitor C_{ref} , comparator offset voltage is stored on integration capacitor C_X , and the sum of the buffer and integrator offset voltages is stored on zero capacitor C_Z . During the auto-zero phase, the comparator output is characterized by an oscillation (limit cycle) of indeterminate waveform and frequency that is filtered and d-c shifted by the level shifter.

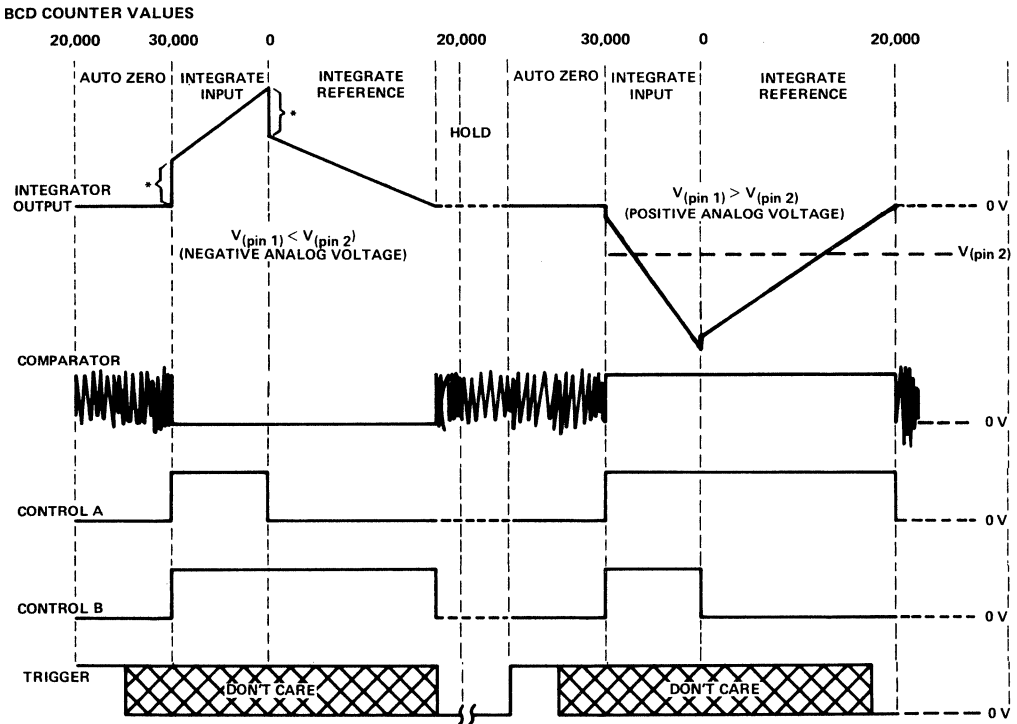

integrate-input phase

The auto-zero phase is completed at a BCD count of 30,000, and high levels are applied to both control inputs to initiate the integrate-input phase. The integrator charges C_X for a fixed time of 10,000 BCD counts at a rate determined by the input voltage. Note that during this phase, the analog inputs see only the high impedance of the noninverting operational amplifier input. Therefore, the integrator responds only to the difference between the analog input terminals, thus providing true differential inputs.

integrate-reference phase

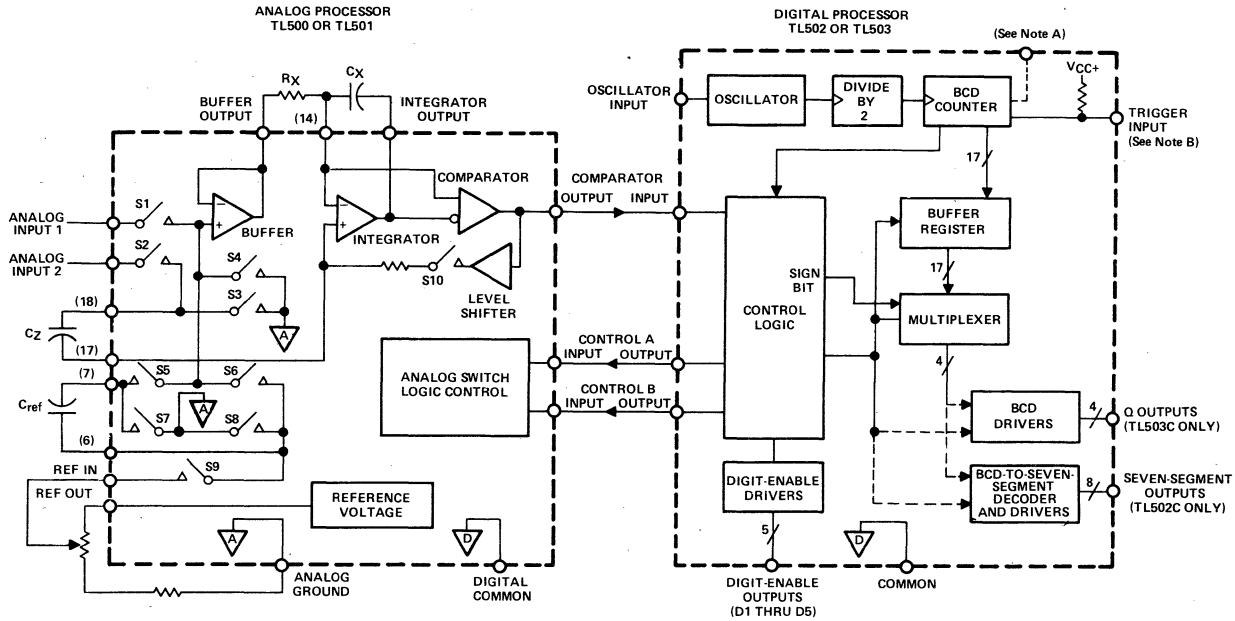

At a BCD count of $39,999 + 1 = 40,000$ or 0, the integrate-input phase is terminated and the integrate-reference phase is begun by sampling the comparator output. If the comparator output is low corresponding to a negative average analog input voltage, the digital processor applies a low and a high to inputs A and B, respectively, to apply the reference voltage stored on C_{REF} to the buffer. If the comparator output is high corresponding to a positive input, inputs A and B are made high and low, respectively, and the negative of the stored reference voltage is applied to the buffer. In either case, the processor automatically selects the proper logic state to cause the integrator to ramp back toward zero at a rate proportional to the reference voltage. The time required to return to zero is measured by the counter in the digital processor. The phase is terminated when the integrator output crosses zero and the counter contents are transferred to the register, or when the BCD counter reaches 20,000 and the over-range indication is activated. When activated, the over-range indication blanks all but the most significant digit and sign.

Seventeen parallel bits (4-1/2 digits) of information are strobed into the buffer register at the end of the integration phase. Information for each digit is multiplexed out to the BCD outputs (TL503C) or the seven-segment drivers (TL502C) at a rate equal to the oscillator frequency divided by 400.

*This step is the voltage at pin 2 with respect to analog ground.

FIGURE 1. VOLTAGE WAVEFORMS AND TIMING DIAGRAM

NOTES: A. Pin 18 of the TL502 provides an output of f_{osc} (oscillator frequency) \div 20,000.
B. The trigger input assumes a high level if not externally connected.

FIGURE 2. BLOCK DIAGRAM OF BASIC ANALOG-TO-DIGITAL CONVERTER USING TL500C or TL501C and TL502C or TL503C

MODE	ANALOG INPUT	COMPARATOR	CONTROLS A AND B	ANALOG SWITCHES CLOSED
Auto Zero	X	Oscillation	L L	S3, S4, S7, S9, S10
Hold†				
Integrate Input	Positive	H	H H	S1, S2
	Negative	L		
Integrate Reference	X	L‡	L H	S3, S6, S7
		H‡	H L	S3, S5, S8

H = High, L = low, X = Irrelevant

† If the trigger input is low at the beginning of the auto-zero cycle, the system will enter the hold mode. A high level (or open circuit) will signal the digital processor to continue or resume normal operation.

‡ This is the state of the comparator output as determined by the polarity of the analog input during the integrate input phase.

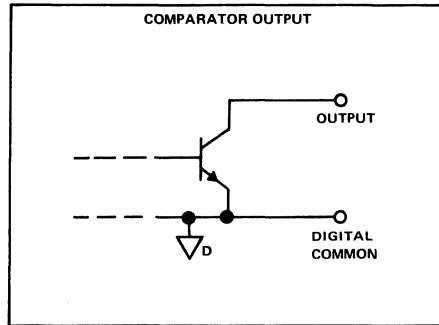

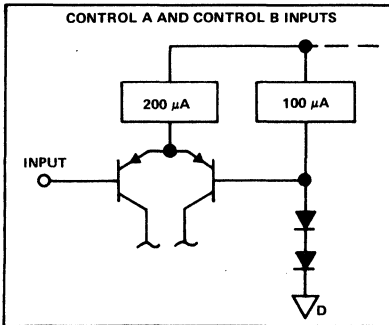

description of analog processors

The TL500C and TL501C analog processors are designed to automatically compensate for internal zero offsets, integrate a differential voltage at the analog inputs, integrate a voltage at the reference input in the opposite direction, and provide an indication of zero-voltage crossing. The external control mechanism may be a microcomputer and software routing, discrete logic, or a TL502C or TL503C controller. The TL500C and TL501C are designed primarily for simple, cost-effective, dual-slope analog-to-digital converters. Both devices feature true differential analog inputs, high input impedance, and an internal reference-voltage source. The TL500C provides 4-1/2-digit readout accuracy when used with a precision external reference voltage. The TL501C provides 100-ppm linearity error and 3-1/2-digit accuracy capability. These devices are manufactured using TI's advanced technology to produce JFET, MOSFET, and bipolar devices on the same chip. The TL500C and TL501C are intended for operation over the temperature range of 0°C to 70°C.

Operating free-air temperature range	-0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds	300°C

- NOTES: 1. Voltage values, except differential voltages, are with respect to the analog ground common pin tied together.
 2. Buffer, integrator, and comparator outputs are not short-circuit protected.
 3. For operation above 25°C free-air temperature, refer to Dissipation Derating Curves, Appendix A. TL500C and TL501C chips are glass mounted.

TL500C, TL501C ANALOG PROCESSORS

recommended operating conditions

		MIN	NOM	MAX	UNIT
Positive supply voltage, V_{CC+}		7	12	15	V
Negative supply voltage, V_{CC-}		-9	-12	-15	V
Reference input voltage, $V_{ref(I)}$		0.1		5	V
Analog input voltage, V_I				±5	V
Differential analog input voltage, V_{ID}				10	V
High-level input voltage, V_{IH}	Control inputs	2			V
Low-level input voltage, V_{IL}	Control inputs			0.8	V
Peak positive integrator output voltage, V_{OM+}		+9			V
Peak negative integrator output voltage, V_{OM-}		-5			V
Full scale input voltage				2 V_{ref}	
Autozero and reference capacitors, C_Z and C_{ref}		0.2			μF
Integrator capacitor, C_X		0.2			μF
Integrator resistor, R_X		15		100	k Ω
Integrator time constant, $R_X C_X$		See Note 4			
Free-air operating temperature, T_A		0		70	$^{\circ}C$
Maximum conversion rate with TL502 or TL503			3	12.5	conv/sec

system electrical characteristics at $V_{CC\pm} = \pm 12 V$, $V_{ref} = 1,000 \pm 0.03 mV$, $T_A = 25^{\circ}C$
(unless otherwise noted) (see Figure 3)

PARAMETER	TEST CONDITIONS	TL501C			TL500C			UNIT
		MIN	TYP	MAX	MIN	TYP	MAX	
Zero error		50	300		10	30	μV	
Linearity error relative to full scale	$V_I = -2 V$ to $2 V$	0.005	0.05		0.001	0.005	%FS	
Full scale temperature coefficient	$T_A = 0^{\circ}C$ to $70^{\circ}C$		6			6	ppm/ $^{\circ}C$	
Temperature coefficient of zero error	$T_A = 0^{\circ}C$ to $70^{\circ}C$		4			1	$\mu V/^{\circ}C$	
Rollover error†		200	500		30	100	μV	
Equivalent peak-to-peak input noise voltage			20			20	μV	
Analog input resistance	Pin 1 or 2		10^9			10^9	Ω	
Common-mode rejection ratio	$V_{IC} = -1 V$ to $+1 V$		86			90	dB	
Current into analog input	$V_I = \pm 5 V$		50			50	pA	
Supply voltage rejection ratio			90			90	dB	

†Rollover error is the voltage difference between the conversion results of the full-scale positive 2 volts and the full-scale negative 2 volts.
NOTE 4. The minimum integrator time constant may be found by use of the following formula:

$$\text{Minimum } R_X C_X = \frac{V_{ID} (\text{full scale}) t_1}{|V_{OM-}| - V_I(\text{pin 2})}$$

where

V_{ID} = voltage at pin with respect to pin 2

$V_I(\text{pin 2})$ = voltage at pin 2 with respect to analog ground

t_1 = input integration time seconds

electrical characteristics at $V_{CC\pm} = \pm 12\text{ V}$, $V_{ref} = 1\text{ V}$, $T_A = 25^\circ\text{C}$ (see Figure 3)

PARAMETER MEASUREMENT INFORMATION

$t_1 = 100 \text{ ms}$
 from
 $R_X C_X = \frac{V_{ID}(\text{full scale}) t_1}{V_{OM} - V_I(\text{PIN 2})}$

- NOTES: C. Tests are started approximately 5 seconds after power-on.
 D. Capacitors used are TRW's X363UW polypropylene or equivalent for C_X , C_{ref} , and C_Z ; however for C_{ref} and C_Z film-dielectric capacitors may be substituted.

FIGURE 3. TEST CIRCUIT CONFIGURATION

external-component selection guide

The autzero capacitor C_Z and reference capacitor C_{ref} should be within the recommended range of operating conditions and should have low-leakage characteristics. Most film-dielectric capacitors and some tantalum capacitors provide acceptable results. Ceramic and aluminum capacitors are not recommended because of their relatively high-leakage characteristics.

The integrator capacitor C_X should also be within the recommended range and must have good voltage linearity and low dielectric absorption. A polypropylene-dielectric capacitor similar to TRW's X363UW is recommended for 4-1/2-digit accuracy. For 3-1/2-digit applications, polyester, polycarbonate, and other film dielectrics are usually suitable. Ceramic and electrolytic capacitors are not recommended.

Stray coupling from the comparator output to any analog pin (in order of importance 17, 18, 14, 7, 6, 13, 1, 2, 15) must be minimized to avoid oscillations. In addition, all power supply pins should be bypassed at the package, for example, by a 0.01-μF ceramic capacitor.

Analog and digital common are internally isolated and may be at different potentials. Digital common can be within 4 volts of positive or negative supply with the logic decode still functioning properly.

The time constant $R_X C_X$ should be kept as near the minimum value as possible and is given by the formula:

$$\text{Minimum } R_X C_X = \frac{V_{ID}(\text{full scale}) t_1}{|V_{OM} - V_I(\text{pin 2})|}$$

where:

- $V_{ID}(\text{full scale})$ = Voltage on pin 1 with respect to pin 2
- t_1 = Input integration time in seconds
- $V_I(\text{pin 2})$ = Voltage on pin 2 with respect to analog ground

TL502C, TL503C DIGITAL PROCESSORS

description of digital processors

The TL502C and TL503C are control logic devices designed to complement the TL500C and TL501C analog processors. They feature interdigit blanking, over-range blanking, an internal oscillator, and a fast display scan rate. The internal-oscillator input is a Schmitt trigger circuit that can be driven by an external clock pulse or provide its own time base with the addition of a capacitor. The typical oscillator frequency is 120 kHz with a 470-picofarad capacitor connected between the oscillator input and ground.

The TL502C provides seven-segment-display output drivers capable of sinking 100 milliamperes and compatible with popular common-anode displays. The TL503C has four BCD output drivers capable of 100-milliampere sink currents. The code (see next page and Figure 4) for each digit is multiplexed to the output drivers in phase with a pulse on the appropriate digit-enable line at a digit rate equal to f_{osc} , divided by 200. Each digit-enable output is capable of sinking 20-milliamperes.

The comparator input of each device, in addition to monitoring the output of the zero-crossing detector in the analog processor, may be used in the display test mode to check for wiring and display faults. A high logic level (2 to 6.5 volts) at the trigger input with the comparator input at or below 6.5 volts starts the integrate-input phase. Voltage levels equal to or greater than 7.9 volts on both the trigger and comparator inputs clear the system and set the BCD counter to 20,000. When normal operation resumes, the conversion cycle is restarted at the auto zero phase.

These devices are manufactured using ^{12}L and bipolar techniques. The TL502C and TL503C are intended for operation from 0°C to 70°C.

TL505C ANALOG-TO-DIGITAL CONVERTER

D2366, OCTOBER 1977 - REVISED SEPTEMBER 1986

- 3-Digit Accuracy (0.1%)
- 10-Bit Resolution
- Automatic Zero
- Internal Reference Voltage
- Single-Supply Operation
- High-Impedance MOS Input
- Designed for Use with TMS1000 Type Microprocessors for Cost-Effective High-Volume Applications
- BI-MOS Technology
- Only 40 mW Typical Power Consumption

N DUAL-IN-LINE PACKAGE (TOP VIEW)

Caution. This device has limited built-in gate protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

description

The TL505C is an analog-to-digital converter building block designed for use with TMS1000 type microprocessors. It contains the analog elements (operational amplifier, comparator, voltage reference, analog switches, and switch drivers) necessary for a unipolar automatic-zeroing dual-slope converter. The logic for the dual-slope conversion can be performed by the associated MPU as a software routine or it can be implemented with other components such as the TL502 logic-control device.

The high-impedance MOS inputs permit the use of less expensive, lower value capacitors for the integration and offset capacitors and permit conversion speeds from 20 per second to 0.05 per second.

The TL505C is a product of TI's BI-MOS process, which incorporates bipolar and MOSFET transistors on the same monolithic circuit. The TL505C is characterized for operation from 0°C to 70°C.

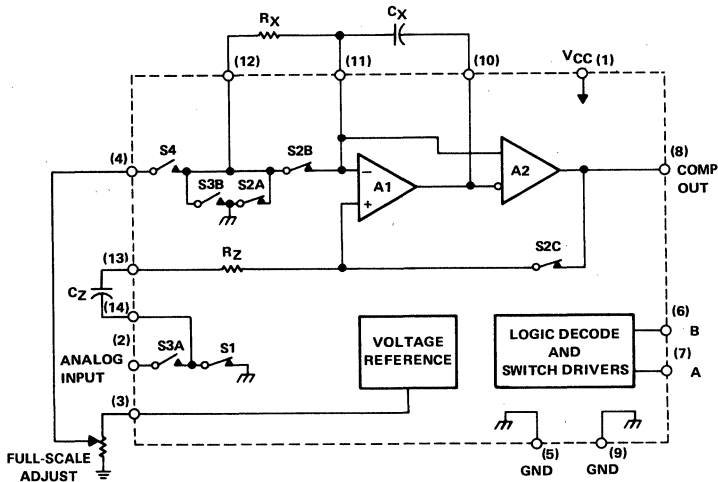

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

DEFINITION OF TERMS

Zero Error

The intercept (b) of the analog-to-digital converter system transfer function $y = mx + b$, where y is the digital output, x is the analog input, and m is the slope of the transfer function, which is approximated by the ratiometric reading.

Linearity Error

The maximum magnitude of the deviation from a straight line between the end points of the transfer function.

Ratiometric Reading

The ratio of negative integration time (t_2) to positive time (t_1).

TL505C ANALOG-TO-DIGITAL CONVERTER

PRINCIPLES OF OPERATION

A block diagram of an MPU system utilizing the TL505C is shown in Figure 1. The TL505C operates in a modified positive-integration three-step dual-slope conversion mode. The A/D converter waveforms during the conversion process are illustrated in Figure 2.

2

Data Acquisition Circuits

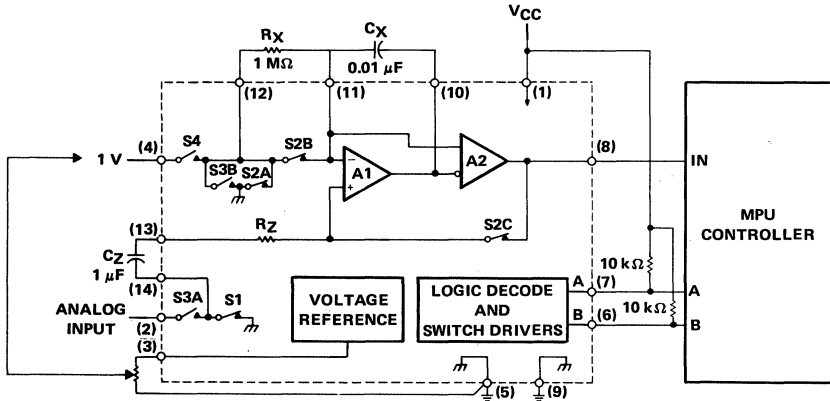

FIGURE 1. FUNCTIONAL BLOCK DIAGRAM OF TL505C INTERFACE WITH A MICROPROCESSOR SYSTEM

FIGURE 2. CONVERSION PROCESS TIMING DIAGRAMS

PRINCIPLES OF OPERATION

The first step of the conversion cycle is the auto-zero period t_0 during which the integrator offset is stored in the auto-zero capacitor and the offset of the comparator is stored in the integrator capacitor. To accomplish this, the MPU takes the A and B inputs both low. This is decoded by the switch drivers, which close S1 and S2. The output of the comparator is connected to the input of the integrator through the low-pass filter consisting of R_Z and C_Z . The closed loop of A1 and A2 will seek a null condition where the offsets of the integrator and comparator are stored in C_Z and C_X , respectively. This null condition is characterized by a high-frequency oscillation at the output of the comparator. The purpose of S2B is to shorten the amount of time required to reach the null condition.

At the conclusion of t_0 , the MPU takes the A and B inputs both high closing S3 and opening all other switches. The input signal V_I is applied to the noninverting input of A1 through C_Z . V_I is then positively integrated by A1. Since the offset of A1 is stored in C_Z , the change in voltage across C_X will be due to only the input voltage. It should be noted that since the input is integrated in a positive integration during t_1 , the output of A1 will be the sum of the input voltage, the integral of the input voltage, and the comparator offset, as shown in Figure 2. The change in voltage across capacitor C_X (V_{CX}) during t_1 is given by

$$\Delta V_{CX(1)} = \frac{V_I t_1}{R_1 C_X} \quad (1)$$

where $R_1 = R_X + R_{S3B}$ and

R_{S3B} is the resistance of switch S3B.

At the end of t_1 , the MPU takes the A input low and the B input high closing S1 and S4 and opening all other switches. In this state, the reference is integrated by A1 in a negative sense until the integrator output reaches the comparator threshold. At this point, the comparator output goes high. This change in state is sensed by the MPU, which terminates t_2 by again taking the A and B inputs both low. During t_2 , the change in voltage across C_X is given by

$$\Delta V_{CX(2)} = \frac{V_{ref} t_2}{R_2 C_X} \quad (2)$$

where $R_2 = R_X + R_{S4} + R_{ref}$ and

R_{ref} is the equivalent resistance of the reference divider.

Since $\Delta V_{CX1} = -\Delta V_{CX2}$, equations (1) and (2) can be combined to give

$$V_I = V_{ref} \frac{R_1 \cdot t_2}{R_2 \cdot t_1} \quad (3)$$

This equation is a variation on the ideal dual-slope equation, which is

$$V_I = V_{ref} \frac{t_2}{t_1} \quad (4)$$

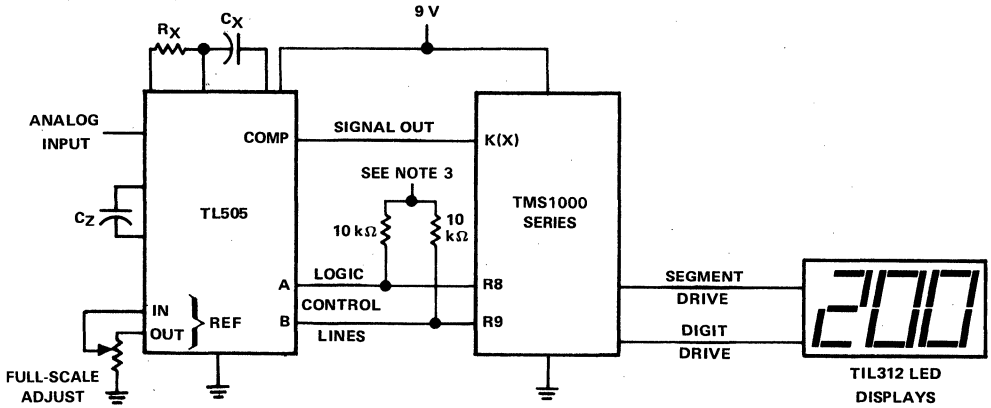

Ideally then, the ratio of R_1/R_2 would be exactly equal to one. In a typical TL505C system where $R_X = 1 \text{ M}\Omega$, the scaling error introduced by the difference in R_1 and R_2 is so small that it can be neglected and equation (3) reduces to (4).

(TOP VIEW)

FUNCTION TABLE

ANALOG INPUT CONDITION	ENABLE	OUTPUT
X	L [†]	H
$V_I < 200$ mV	H	L
$V_{ramp} > V_I > 200$ mV	H	H
$V_I > V_{ramp}$	H	L

[†]Low level on enable also inhibits the reset function.
H = high level, L = low level, X = irrelevant

A high level on the reset pin clears the counter to zero, which sets the internal ramp to 0.75 V_{CC} . Internal pull down resistors keep the reset and enable pins low when not connected.

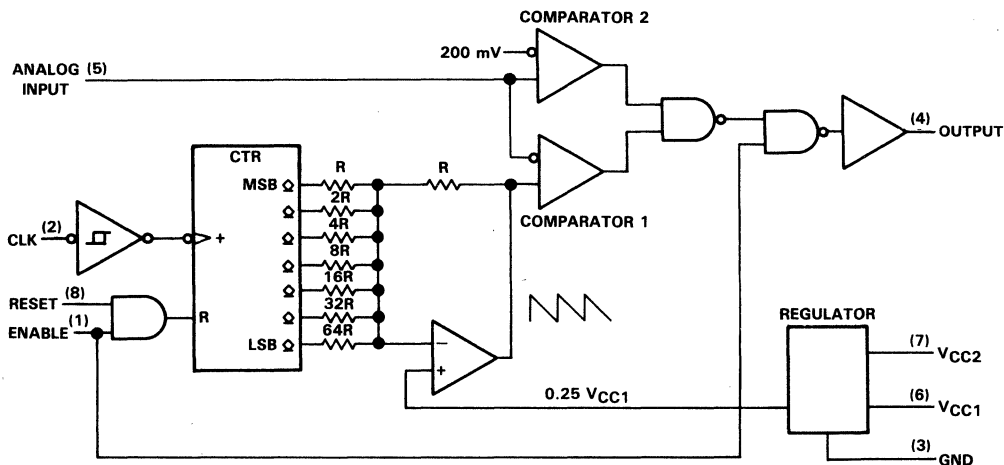

description

The TL507 is a low-cost single-slope analog-to-digital converter designed to convert analog input voltages between 0.25 V_{CC1} and 0.75 V_{CC1} into a pulse-width-modulated output code. It contains a 7-bit synchronous counter, a binary weighted resistor ladder network, an operational amplifier, two comparators, a buffer amplifier, an internal regulator, and necessary logic circuitry. Integrated-injection logic (i^2L) technology makes it possible to offer this complex circuit at low cost in a small dual-in-line 8-pin package.

In continuous operation, it is possible to obtain conversion speeds up to 1000 per second. The TL507 requires external signals for clock, reset, and enable. Versatility and simplicity of operation, coupled with low cost, make this converter especially useful for a wide variety of applications.

The TL507C is characterized for operation from 0°C to 70°C, and the TL507I is characterized for operation from -40°C to 85°C.

2

Data Acquisition Circuits

definitions

zero error

The absolute value of the difference between the actual analog voltage at the 01H-to-00H transition and the ideal analog voltage at that transition.

overall error

The magnitude of the deviation from a straight line between the endpoints of the transfer function.

differential nonlinearity

The maximum deviation of an analog-value change associated with a 1-bit code change (1 clock pulse) from its theoretical value of 1 LSB.

PARAMETER MEASUREMENT INFORMATION

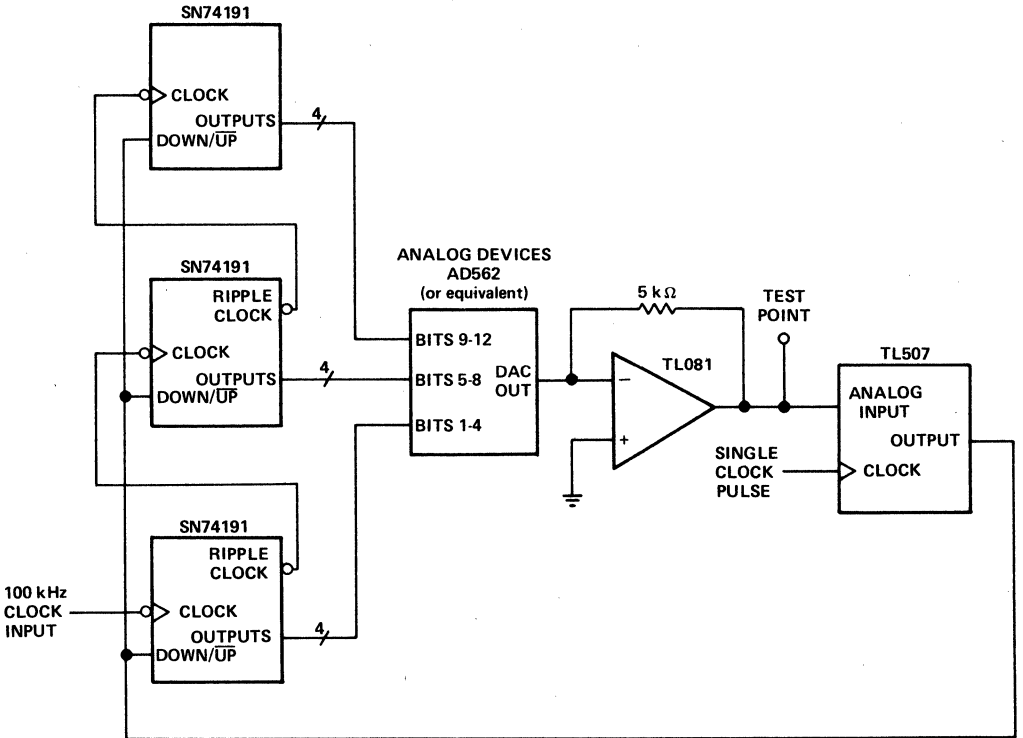

FIGURE 1. MONOTONICITY AND NONLINEARITY TEST CIRCUIT

PRINCIPLES OF OPERATION

The TL507 is a single-slope analog-to-digital converter. All single-slope converters are basically voltage-to-time or current-to-time converters. A study of the functional block diagram shows the versatility of the TL507.

An external clock signal is applied through a buffer to a negative-edge-triggered synchronous counter. Binary-weighted resistors from the counter are connected to an operational amplifier used as an adder. The operational amplifier generates a signal that ramps from $0.75 \cdot V_{CC1}$ down to $0.25 \cdot V_{CC1}$. Comparator 1 compares the ramp signal to the analog input signal. Comparator 2 functions as a fault defector. With the analog input voltage in the range $0.25 \cdot V_{CC1}$ to $0.75 \cdot V_{CC1}$, the duty cycle of the output signal is determined by the unknown analog input as shown in Figure 2 and the Function Table.

For illustration assume $V_{CC1} = 5.12 \text{ V}$,

$$0.25 \cdot V_{CC1} = 1.28 \text{ V}$$

$$1 \text{ binary count} = \frac{(0.75 - 0.25) V_{CC1}}{128} = 20 \text{ mV}$$

$$0.75 \cdot V_{CC1} - 1 \text{ count} = 3.82 \text{ V}$$

The output is an open-collector n-p-n transistor capable of withstanding up to 18 volts in the off state. The output is current limited to the 8- to 12-milliampere range; however, care must be taken to ensure that the output does not exceed 5.5 volts in the on state.

The voltage regulator section allows operation from either an unregulated 8- to 18-volt V_{CC2} source or a regulated 3.5- to 6-volt V_{CC1} source. Regardless of which external power source is used, the internal circuitry operates at V_{CC1} . When operating from a V_{CC1} source, V_{CC2} may be connected to V_{CC1} or left open. When operating from a V_{CC2} source, V_{CC1} can be used as a reference voltage output.

TL601, TL604, TL607, TL610 P-MOS ANALOG SWITCHES

D2161, JUNE 1976—REVISED OCTOBER 1986

- Switches ± 10 -V Analog Signals
- TTL Logic Capability
- 5- to 30-V Supply Ranges
- Low (100 Ω) On-State Resistance
- High (10¹¹ Ω) Off-State Resistance
- 8-Pin Functions

description

The TL601, TL604, TL607, and TL610 are a family of monolithic P-MOS analog switches that provide fast switching speeds with high r_{off}/r_{on} ratio and no offset voltage. The p-channel enhancement-type MOS switches will accept analog signals up to ± 10 volts and are controlled by TTL-compatible logic inputs. The monolithic structure is made possible by BI-MOS technology, which combines p-channel MOS with standard bipolar transistors.

These switches are particularly suited for use in military, industrial, and commercial applications such as data acquisition, multiplexers, A/D and D/A converters, MODEMS, sample-and-hold systems, signal multiplexing, integrators, programmable operational amplifiers, programmable voltage regulators, crosspoint switching networks, logic interface, and many other analog systems.

The TL601 is an SPDT switch with two logic control inputs. The TL604 is a dual complementary SPST switch with a single control input. The TL607 is an SPDT switch with one logic control input and one enable input. The TL610 is an SPST switch with three logic control inputs. The TL610 features a higher r_{off}/r_{on} ratio than the other members of the family.

The TL601M, TL604M, TL607M, and TL610M are characterized for operation over the full military temperature range of -55°C to 125°C , the TL601I, TL604I, TL607I, and TL610I are characterized for operation from -25°C to 85°C , and the TL601C, TL604C, TL607C, and TL610C are characterized for operation from 0°C to 70°C .

2

Data Acquisition Circuits

Figure 1 shows power supply boundary conditions for proper operation of the TL601 Series. The range of operation for supply V_{CC+} from +5 V to +25 V is shown on the vertical axis. The range of V_{CC-} from -5 volts to -25 volts is shown on the horizontal axis. A recommended 30-volt maximum voltage differential from V_{CC+} to V_{CC-} governs the maximum V_{CC+} for a chosen V_{CC-} (or vice versa). A minimum recommended difference of 15 volts from V_{CC+} to V_{CC-} and the boundaries shown in Figure 1 allow the designer to select the proper combinations of the two supplies.

The designer-selected V_{CC+} for a chosen V_{CC-} supply values limit the maximum input voltage that can be applied to either switch terminal; that is, the input voltage should be between $V_{CC-} + 8$ V and V_{CC+} to keep the on-state resistance within specified limits.

description

The TLC04 and TLC14 are monolithic Butterworth low-pass switched-capacitor filters. Each is designed as a low-cost, easy-to-use device and to provide accurate fourth-order low-pass filter functions in circuit design configurations.

Each filter features cutoff frequency stability that is dependent only on the external-clock frequency stability. The cutoff frequency is clock tunable and has a clock-to-cutoff frequency ratio of 50:1 with less than $\pm 0.8\%$ error for the TLC04 and a clock-to-cutoff frequency ratio of 100:1 with less than $\pm 1\%$ error for the TLC14. The input clock features self-clocking or TTL- or CMOS-compatible options in conjunction with the level shift (LS) pin.

The TLC04 and TLC14 are characterized for operation from 0°C to 70°C.

pin description

PIN NAME	NO.	I/O	DESCRIPTION
AGND	6	I	Analog Ground -- The noninverting input to the operational amplifiers of the Butterworth fourth-order low-pass filter.
CLKIN	1	I	Clock In -- The clock input terminal for CMOS-compatible clock or self-clocking options. For either option, the Level Shift (LS) terminal is at V_{CC-} . For self-clocking, a resistor is connected between the CLKIN and CLKR terminal pins and a capacitor is connected from the CLKIN terminal pin to ground.
CLKR	2	I	Clock R -- The clock input for a TTL-compatible clock. For a TTL clock, the level shift pin is connected to mid-supply and the CLKIN pin may be left open, but it is recommended that it be connected to either V_{CC+} or V_{CC-} .
FILTER IN	8	I	Filter Input
FILTER OUT	5	O	Butterworth fourth-order low-pass Filter Output
LS	3	I	Level Shift -- This terminal accommodates the various input clocking options. For CMOS-compatible clocks or self-clocking, the level-shift terminal is at V_{CC-} and for TTL-compatible clocks, the level-shift terminal is at mid-supply.
V_{CC+}	7	I	Positive supply voltage terminal
V_{CC-}	4	I	Negative supply voltage terminal

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, $V_{CC\pm}$ (see Note 1)	± 7 V
Operating free-air temperature range	0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

NOTE 1: All voltage values are with respect to the AGND terminal.

recommended operating conditions

	TLC04		TLC14		UNIT
	MIN	MAX	MIN	MAX	
V_{CC+} Positive supply voltage	2.5	6	2.5	6	V
V_{CC-} Negative supply voltage	-2.5	-6	-2.5	-6	V
V_{IH} High-level input voltage	2		2		V
V_{IL} Low-level input voltage		0.8		0.8	V
f_{clock} Clock frequency (see Note 2)	5	1×10^6	10	1×10^6	Hz
f_{co} Cutoff frequency (see Note 3)	0.1	20×10^3	0.1	10×10^3	Hz
T_A Operating free-air temperature	0	70	0	70	°C

- NOTES: 2. Above 250 kHz, the input clock duty cycle should be at 50% to allow the operational amplifiers the maximum time to settle while processing analog samples.
3. The cutoff frequency is defined as the frequency where the response is 3.01 dB less than the dc gain of the filter.

description

The TLC0820A and TLC0820B are Advanced LinCMOS™ 8-bit analog-to-digital converters each consisting of two 4-bit "flash" converters, a 4-bit digital-to-analog converter, a summing (error) amplifier, control logic, and a result latch circuit. The modified "flash" technique allows low-power integrated circuitry to complete an 8-bit conversion in 1.4 microseconds. The on-chip track-and-hold circuit has a 100-nanosecond sample window and allows the TLC0820A and TLC0820B to convert continuous analog signals having slew rates of up to 100 millivolts per microsecond without external sampling components. TTL-compatible three-state output drivers and two modes of operation allow interfacing to a variety of microprocessors. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

The TLC0820AM and TLC0820BM are available in both the N plastic and the J ceramic packages and are characterized for operation over the full military temperature range of -55°C to 125°C. The TLC0820AI and TLC0820BI are characterized for operation from -40°C to 85°C. The TLC0820AC and TLC0820BC are characterized for operation from 0°C to 70°C.

Advanced LinCMOS is a trademark of Texas Instruments.

PRODUCT PREVIEW

PIN		DESCRIPTION
NAME	NUMBER	
ANLG IN	1	Analog input
\overline{CS}	13	This input must be low in order for \overline{RD} or \overline{WR} to be recognized by the ADC.
D0	2	Three-state data output, bit 1 (LSB)
D1	3	Three-state data output, bit 2
D2	4	Three-state data output, bit 3
D3	5	Three-state data output, bit 4
D4	14	Three-state data output, bit 5
D5	15	Three-state data output, bit 6
D6	16	Three-state data output, bit 7
D7	17	Three-state data output, bit 8 (MSB)
GND	10	Ground
\overline{INT}	9	In the WRITE-READ mode, the interrupt output, \overline{INT} , going low indicates that the internal count-down delay time, $t_{d(int)}$, is complete and the data result is in the output latch. $t_{d(int)}$ is typically 800 ns starting after the rising edge of the \overline{WR} input (see operating characteristics and Figure 3). If \overline{RD} goes low prior to the end of $t_{d(int)}$, \overline{INT} goes low at the end of t_{dRIL} and the conversion results are available sooner (see Figure 2). \overline{INT} is reset by the rising edge of either \overline{RD} or \overline{CS} .
MODE	7	Mode-selection input. It is internally tied to GND through a 50- μ A current source, which acts like a pull-down resistor. READ mode: Occurs when this input is low. WRITE-READ mode: Occurs when this input is high.
NC	19	No internal connection
\overline{OFLW}	18	Normally the \overline{OFLW} output is a logical high. However, if the analog input is higher than the V_{REF+} , \overline{OFLW} will be low at the end of conversion. It can be used to cascade 2 or more devices to improve resolution (9 or 10-bits).
\overline{RD}	8	In the WRITE-READ mode with \overline{CS} low, the 3-state data outputs D0 through D7 are activated when \overline{RD} goes low. \overline{RD} can also be used to increase the conversion speed by reading data prior to the end of the internal count-down delay time. As a result, the data transferred to the output latch is latched after the falling edge of \overline{RD} . In the READ mode with \overline{CS} low, the conversion starts with \overline{RD} going low. \overline{RD} also enables the three-state data outputs upon completion of the conversion. The RDY output going into the high-impedance state and \overline{INT} going low indicates completion of the conversion.
REF -	11	This input voltage is placed on the bottom of the resistor ladder.
REF +	12	This input voltage is placed on the top of the resistor ladder.
VCC	20	Power supply voltage
\overline{WR}/RDY	6	In the WRITE-READ mode with \overline{CS} low, the conversion is started on the falling edge of the \overline{WR} input signal. The result of the conversion is strobed into the output latch after the internal count-down delay time, $t_{d(int)}$, provided that the \overline{RD} input does not go low prior to this time. $t_{d(int)}$ is approximately 800 ns. In the READ mode, RDY (an open-drain output) will go low after the falling edge of \overline{CS} , and will go into the high-impedance state when the conversion is strobed into the output latch. It is used to simplify the interface to a microprocessor system.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

The TLC0820A and TLC0820B each employ a combination of "sampled-data" comparator techniques and "flash" techniques common to many high-speed converters. Two 4-bit "flash" analog-to-digital conversions are used to give a full 8-bit output.

The recommended analog input voltage range for conversion is -0.1 V to $V_{CC} + 0.1\text{ V}$. Analog input signals that are less than $V_{REF-} + \frac{1}{2}\text{ LSB}$ or greater than $V_{REF+} - \frac{1}{2}\text{ LSB}$ convert to 00000000 or 11111111 respectively. The reference inputs are fully differential with common-mode limits defined by the supply rails. The reference input values define the full-scale range of the analog input. This allows the gain of the ADC to be varied for ratiometric conversion by changing the V_{REF+} and V_{REF-} voltages.

The device operates in two modes, read (only) and write-read, which are selected by the MODE pin (pin 7). The converter is set to the read (only) mode when pin 7 is low. In the read mode, the \overline{WR}/RDY pin is used as an output and is referred to as the "ready" pin. In this mode, a low on the "ready" pin while \overline{CS} is low indicates that the device is busy. Conversion starts on the falling edge of \overline{RD} and is completed no more than 2.5 microseconds later when \overline{INT} falls and the "ready" pin returns to a high-impedance state. Data outputs also change from high-impedance to active states at this time. After the data is read, \overline{RD} is taken high, \overline{INT} returns high, and the data outputs return to their high-impedance states.

The converter is set to the write-read mode when pin 7 is high and \overline{WR}/RDY is referred to as the "write" pin. Taking \overline{CS} and the "write" pin low selects the converter and initiates measurement of the input signal. Approximately 600 nanoseconds after the "write" pin returns high, the conversion is completed. Conversion starts on the rising edge of \overline{WR}/RDY in the write-read mode.

The high-order 4-bit "flash" ADC measures the input by means of 16 comparators operating simultaneously. A high precision 4-bit DAC then generates a discrete analog voltage from the result of that conversion. After a time delay, a second bank of comparators does a low-order conversion on the analog difference between the input level and the high-order DAC output. The results from each of these conversions enter an 8-bit latch and are output to the three-state buffers on the falling edge of \overline{RD} .

 Linear Technology LTC1060

description

The TLC10 and TLC20 are monolithic general-purpose switched-capacitor CMOS filters each containing two independent active-filter sections. Each device facilitates configuration of Butterworth, Bessel, Cauer, or Chebyshev filter design.

Filter features include cutoff frequency stability that is dependent only on the external clock frequency stability and minimal response deviation over time and temperature. Features also include a critical-frequency times filter quality (Q) factor range of up to 200 kilohertz.

With external clock and resistors, each filter section can be used independently to produce various second-order functions or both sections can be cascaded to produce fourth-order functions. For functions greater than fourth-order, ICs can be cascaded.

The TLC10 and TLC20 are characterized for operation from 0°C to 70°C.

ADVANCE INFORMATION

PIN		I/O	DESCRIPTION
NAME	NO.		
AGND	15	I	Analog Ground — The noninverting inputs to the input operational amplifiers of both filter sections. This terminal should be at ground for dual supplies or at mid-supply level for single-supply operation.
1APIN	5	I	All-Pass Inputs — The all-pass input to the summing amplifier of each respective filter section used for all-pass filter applications in configuration modes 1a, 4, 5, and 6. This terminal should be driven from a source having an impedance of less than 1 kilohm. In all other modes, this terminal is grounded. See Typical Application Data.
2APIN	16		
1BP	2	O	Band-Pass Outputs — The band-pass output of each respective filter section provides the second-order band-pass filter functions.
2BP	19		
CF/CL	12	I	Center Frequency/Current Limit — This input terminal provides the option to select the input-clock-to-center-frequency ratio of 50:1 or 100:1 or to limit the current of the IC. For a 50:1 ratio, the CF/CL terminal is set to V_{DD+} . For a 100:1 ratio, the CF/CL terminal is set to ground for dual supplies or to mid-supply level for single-supply operation. For current limiting, the CF/CL terminal is set to V_{DD-} . This aborts filtering and limits the IC current to 0.5 milliamperes.
1CLK	10	I	Clock Inputs — The clock input to the two-phase nonoverlapping generator of each respective filter section is used to generate the center frequency of the complex pole pair second-order function. Both clocks should be of the same level (TTL or CMOS) and have duty cycles close to 50%, especially when clock frequencies (f_{clock}) greater than 200 kilohertz are used. At this duty cycle, the operational amplifiers have the maximum time to settle while processing analog samples.
2CLK	11		
1IN –	4	I	Inverting Inputs — The inverting input side of the input operational amplifier whose output drives the summing amplifier of each respective filter section.
2IN –	17		
1LP	1	O	Low-Pass Outputs — The low-pass outputs of the second-order filters.
2LP	20		
LS	9	I	Level Shift — This terminal accommodates various input clock levels of bipolar (CMOS) or unipolar (TTL or other clocks) to function with single or dual supplies. For CMOS (± 5 -volt) clocks, V_{DD-} or ground is applied to the LS terminal. For TTL and other clocks, ground is applied to the LS terminal.
1NAH	3	O	Notch, All-Pass, or High-Pass Outputs — The output of each respective filter section can be used to provide either a second-order notch, all-pass, or high-pass output filter function, depending on circuit configuration.
2NAH	18		
SW	6	I	Switch Input — This input terminal is used to control internal switches to connect either the AGND input or the LP output to one of the inputs of the summing amplifier. The terminal controls both independent filter sections and places them in the same configuration simultaneously. If V_{CC-} is applied to the SW terminal, the AGND input terminal will be connected to one of the inputs of each summing amplifier. If V_{CC+} is applied to the SW terminal, the LP output will be connected to one of the inputs of the summing amplifier.
V_{CC+}	7		Analog positive supply voltage terminal
V_{CC-}	14		Analog negative supply voltage terminal
V_{DD+}	8		Digital positive supply voltage terminal
V_{DD-}	13		Digital negative supply voltage terminal

Data Acquisition Circuits

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Analog supply voltage, $V_{CC\pm}$ (see Note 1)	± 7 V
Digital supply voltage, $V_{DD\pm}$	± 7 V
Operating free-air temperature range	0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: N package	260°C
Case temperature for 10 seconds: FN package	260°C

NOTE 1: All voltage values are with respect to the AGND terminal.

recommended operating conditions

	MIN	NOM	MAX	UNIT
Analog supply voltage, $V_{CC\pm}$, (see Note 2)	± 4	± 5	± 6	V
Digital supply voltage, $V_{DD\pm}$, (see Note 2)	± 4	± 5	± 6	V
Clock frequency, f_{clock} , (see Note 3)	0.008		1.0	MHz
Operating free-air temperature, T_A	0		70	°C

NOTES: 2. A common supply voltage source should be used for the analog and digital supply voltages. Although each has separate terminals, they are connected together internally at the substrate. V_{CC+} and V_{DD+} can be connected together at the device terminals or at the supply voltage source. The same is true for V_{CC-} and V_{DD-} .

3. Both input clocks should be of the same level type (TTL or CMOS), and their duty cycles should be at 50% above 200 kHz to allow the operational amplifiers the maximum time to settle while processing analog samples.

electrical characteristics at $V_{CC\pm} = \pm 5$ V, $V_{DD\pm} = \pm 5$ V, $T_A = 25$ °C (unless otherwise noted)

ADVANCE INFORMATION

TYPICAL APPLICATION DATA

modes of operation

The TLC10 and TLC20 are switched-capacitor (sampled-data) filters that closely approximate continuous filters. Each filter section is designed to approximate the response of a second-order variable filter. When the sampling frequency is much larger than the frequency band of interest, the sampled-data filter is a good approximation to its continuous time equivalent. In the case of the TLC10 and TLC20, the ratio is about 50:1 or 100:1. To fully describe their transfer function, a time domain approach would be appropriate. Since this may appear cumbersome, the following application examples are based on the well known frequency domain. It should be noted that in order to obtain the actual filter response, the filter's response must be examined in the z-domain.

$$f_o = f_{clock}/100 \text{ or } f_{clock}/50$$

$$f_{notch} = f_o$$

$$H_{OLP} = -R2/R1 \text{ (as } f \rightarrow 0)$$

$$H_{OBP} = -R3/R1 \text{ (at } f = f_o)$$

$$H_{ON} = \text{notch gain} \begin{cases} \text{as } f \text{ approaches } 0 & -R2/R1 \\ \text{as } f \text{ approaches } 0.5 f_{clock} & \end{cases}$$

$$Q = f_o/BW = R3/R2$$

Circuit dynamics:

The following expressions determine the swing at each output as a function of the desired Q of the second-order function.

$$H_{OLP} = H_{OBP}/Q \text{ or } H_{OLP} \times Q = H_{ON} \times Q$$

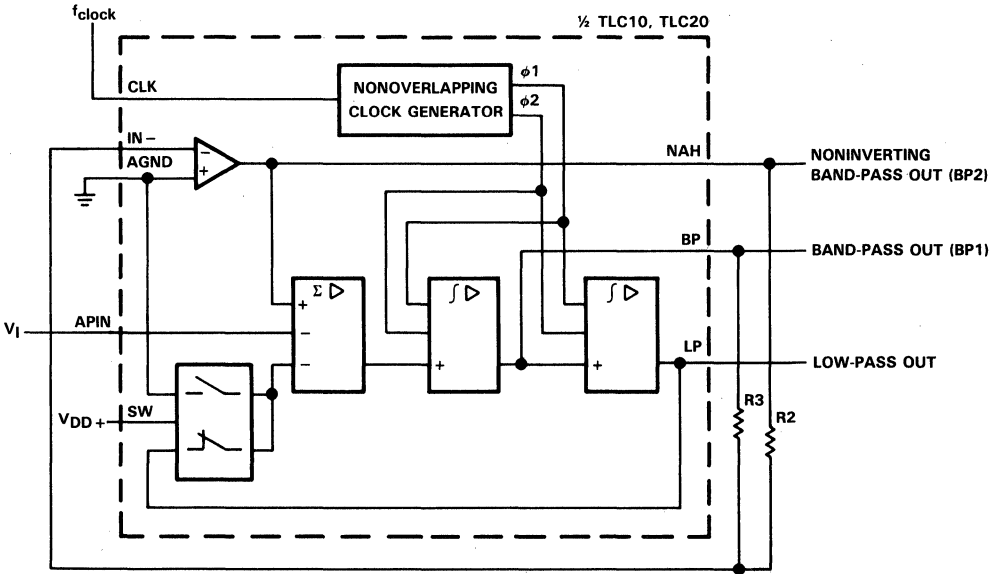

$$H_{OLP}(\text{peak}) = Q \times H_{OLP} \text{ (for high } Qs)$$

FIGURE 1. MODE 1 FOR NOTCH, BAND-PASS, AND LOW-PASS OUTPUTS: $f_{notch} = f_o$

TYPICAL APPLICATION DATA

2

Data Acquisition Circuits

$$f_o = f_{\text{clock}}/100 \text{ or } f_{\text{clock}}/50$$

$$Q = R3/R2$$

$$H_{\text{OLP}} = -1 \quad H_{\text{OLP}}(\text{peak}) = Q \times H_{\text{OLP}} \text{ (for high } Q\text{s)}$$

$$H_{\text{OBP1}} = -R3/R2$$

$$H_{\text{OBP2}} = 1 \text{ (noninverting)}$$

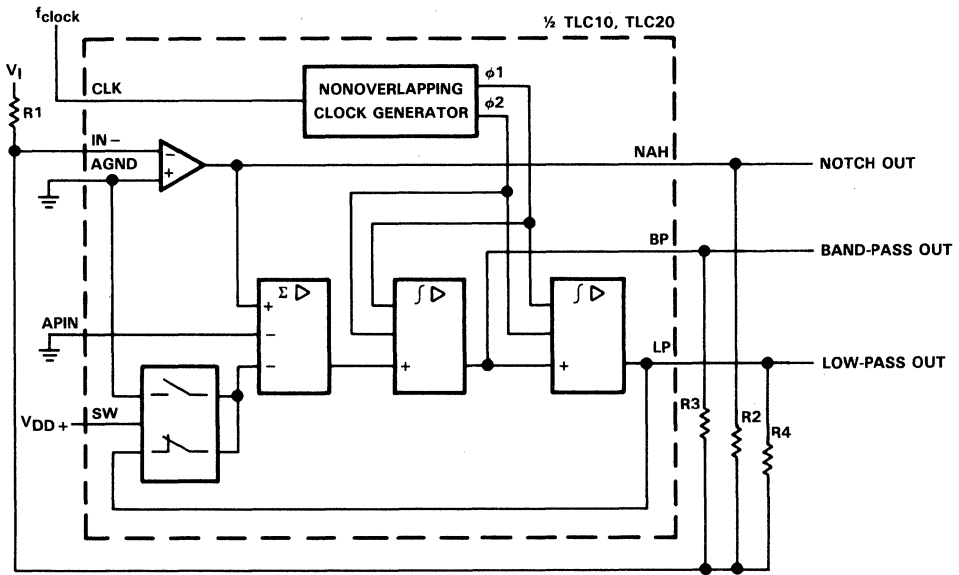

Circuit dynamics:

$$H_{\text{OBP1}} = Q$$

FIGURE 2. MODE 1a FOR NONINVERTING BAND-PASS AND LOW-PASS OUTPUTS

ADVANCE INFORMATION

TYPICAL APPLICATION DATA

$$f_o = f_{notch} \times \sqrt{R2/R4 + 1}$$

$$f_{notch} = f_{clock}/100 \text{ or } f_{clock}/50$$

$$Q = \frac{\sqrt{R2/R4 + 1}}{R2/R3}$$

$$H_{OLP} \text{ (as } f \text{ approaches } 0) = \frac{-R2/R1}{R2/R4 + 1}$$

$$H_{OBP} \text{ (at } f = f_o) = -R3/R1$$

$$H_{ON1} \text{ (as } f \text{ approaches } 0) = \frac{-R2/R1}{R2/R4 + 1}$$

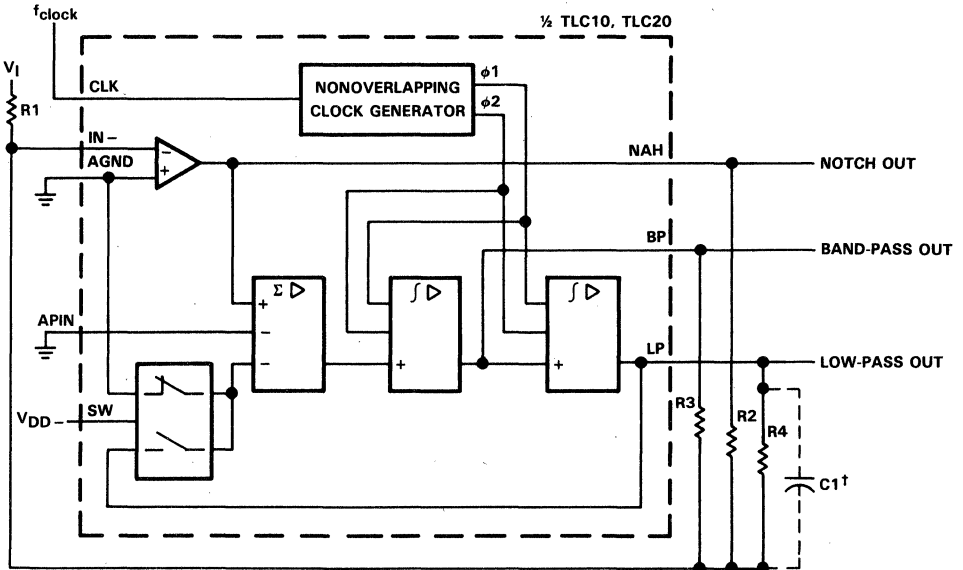

$$H_{ON2} \text{ (as } f \text{ approaches } 0.5 f_{clock}) = -R2/R1$$

Circuit dynamics:

$$H_{OBP} = Q \sqrt{H_{OLP} \times H_{ON2}} = Q \sqrt{H_{ON1} \times H_{ON2}}$$

FIGURE 3. MODE 2 FOR NOTCH, BAND-PASS, AND LOW-PASS OUTPUTS: $f_{notch} < f_o$

TYPICAL APPLICATION DATA

$$f_o = (f_{\text{clock}}/100 \text{ or } f_{\text{clock}}/50) \sqrt{R2/R4}$$

$$Q = \sqrt{R2/R4} \times R3/R2$$

$$H_{\text{OHP}} \text{ (as } f \text{ approaches } 0.5 f_{\text{clock}}) = -R2/R1$$

$$H_{\text{OLP}} \text{ (as } f \text{ approaches } 0) = -R4/R1$$

$$H_{\text{OBP}} \text{ (at } f = f_o) = -R3/R1$$

Circuit dynamics:

$$R2/R4 = H_{\text{OHP}}/H_{\text{OLP}}; H_{\text{OBP}} = \sqrt{H_{\text{OHP}} \times H_{\text{OLP}}} \times Q$$

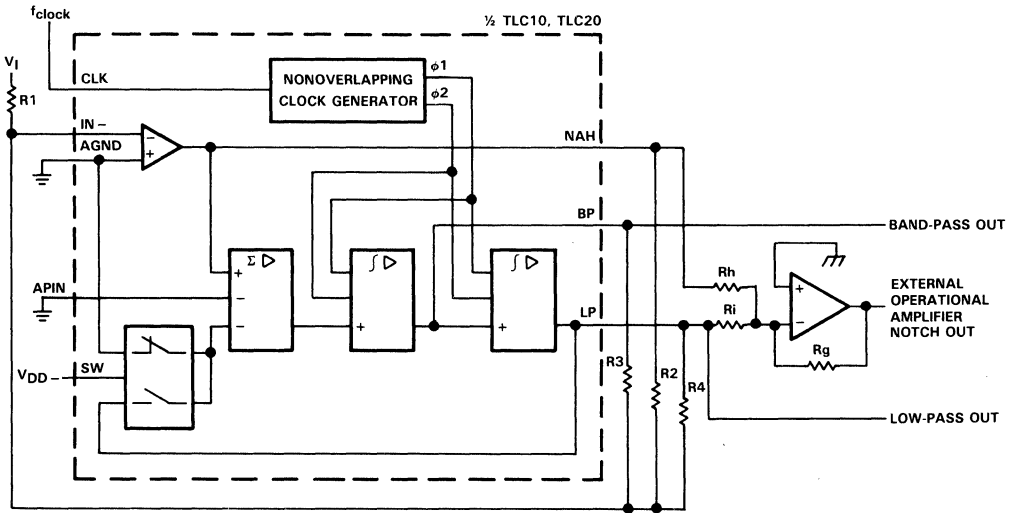

$$H_{\text{OLP}} \text{ (peak)} = Q \times H_{\text{OLP}} \text{ (for high } Q\text{s)}$$

$$H_{\text{OHP}} \text{ (peak)} = Q \times H_{\text{OHP}} \text{ (for high } Q\text{s)}$$

[†]In this mode, the feedback loop is closed around the input summing amplifier; the finite GBW product of this operational amplifier will cause a slight Q enhancement. If this is a problem, connect a low-value capacitor (10 pF to 100 pF) across R4 to provide some phase lead.

FIGURE 4. MODE 3 FOR HIGH-PASS, BAND-PASS, AND LOW-PASS OUTPUTS

TYPICAL APPLICATION DATA

$$f_o = (f_{clock}/100 \text{ or } f_{clock}/50) \sqrt{R_2/R_4}$$

$$Q = \sqrt{R_2/R_4} \times R_3/R_2$$

$$HOHP = -R_2/R_1$$

$$HOBP = -R_3/R_1$$

$$HOLP = -R_4/R_1$$

$$f_{notch} = (f_{clock}/100 \text{ or } f_{clock}/50) \sqrt{R_h/R_i}$$

$$HON \text{ (at } f = f_o) = | Q (R_g/R_i \times HOLP - R_g/R_h \times HOHP) |$$

$$HON1 \text{ (as } f \text{ approaches } 0) = R_g/R_i \times HOLP$$

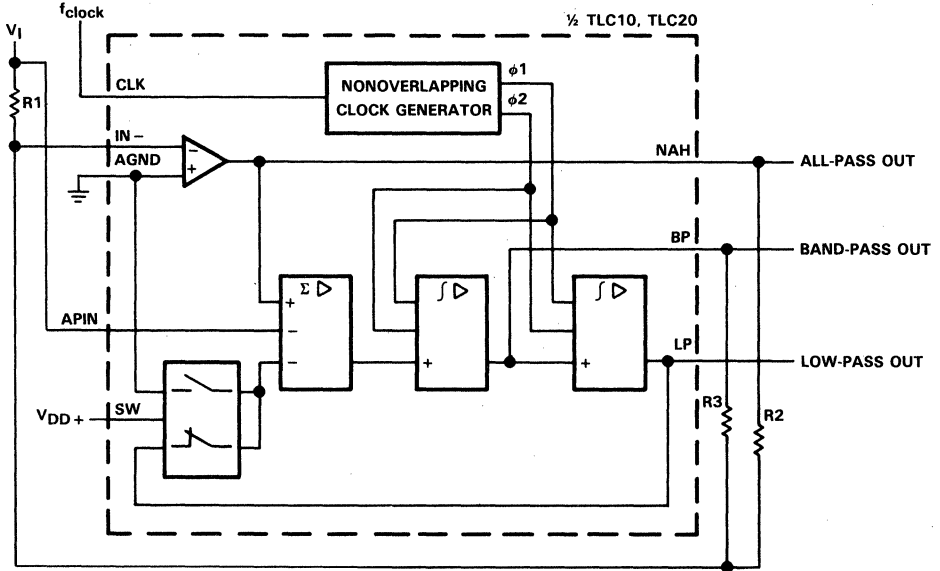

$$HON2 \text{ (as } f \text{ approaches } 0.5 f_{clock}) = -R_g/R_h \times HOHP$$

FIGURE 5. MODE 3a FOR HIGH-PASS, BAND-PASS, LOW-PASS, AND NOTCH OUTPUTS WITH EXTERNAL OPERATIONAL AMPLIFIER

TYPICAL APPLICATION DATA

2

Data Acquisition Circuits

$$f_o = f_{clock}/100 \text{ or } f_{clock}/50$$

$$f_z = f_o^\dagger$$

$$Q = f_o/BW = R3/R2$$

$$Q_z = R3/R1$$

$$H_{OAP} \text{ (at } 0 \leq f \leq 0.5 f_{clock}) = -R2/R1 = -1$$

(for AP output $R1 = R2$)

$$H_{OLP} \text{ (as } f \text{ approaches } 0) = -(R2/R1 + 1) = -2$$

$$H_{OBP} \text{ (at } f = f_o) = -R3/R2 (R2/R1 + 1) = -2 (R3/R2)$$

Circuit dynamics:

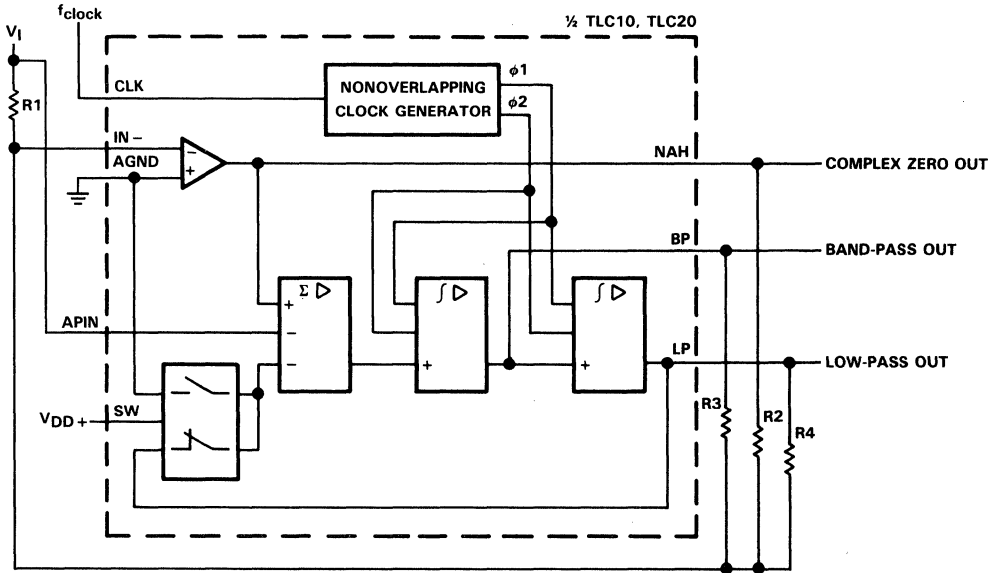

$$H_{OBP} = H_{OLP} \times Q = (H_{OAP} + 1) Q$$

[†]Due to the sampled-data nature of the filter, a slight mismatch of f_z and f_o occurs causing a 0.4-dB peaking around f_o of the all-pass filter amplitude response (which theoretically should be a straight line). If this is unacceptable, Mode 5 is recommended.

FIGURE 6. MODE 4 FOR ALL-PASS, BAND-PASS, AND LOW-PASS OUTPUTS

ADVANCE INFORMATION

TYPICAL APPLICATION DATA

$$f_o = \sqrt{R2/R4 + 1} \times (f_{clock}/100 \text{ or } f_{clock}/50)$$

$$f_z = \sqrt{1 - R1/R4} \times (f_{clock}/100 \text{ or } f_{clock}/50)$$

$$Q = \sqrt{R2/R4 + 1} \times R3/R2$$

$$Q_z = \sqrt{1 - R1/R4} \times R3/R1$$

$$H_{OZ1} \text{ (as } f \text{ approaches } 0) = R2 (R4 - R1)/R1 (R2 + R4)$$

$$H_{OZ2} \text{ (as } f \text{ approaches } 0.5 f_{clock}) = R2/R1$$

$$H_{OBP} = (R2/R1 + 1) \times R3/R2$$

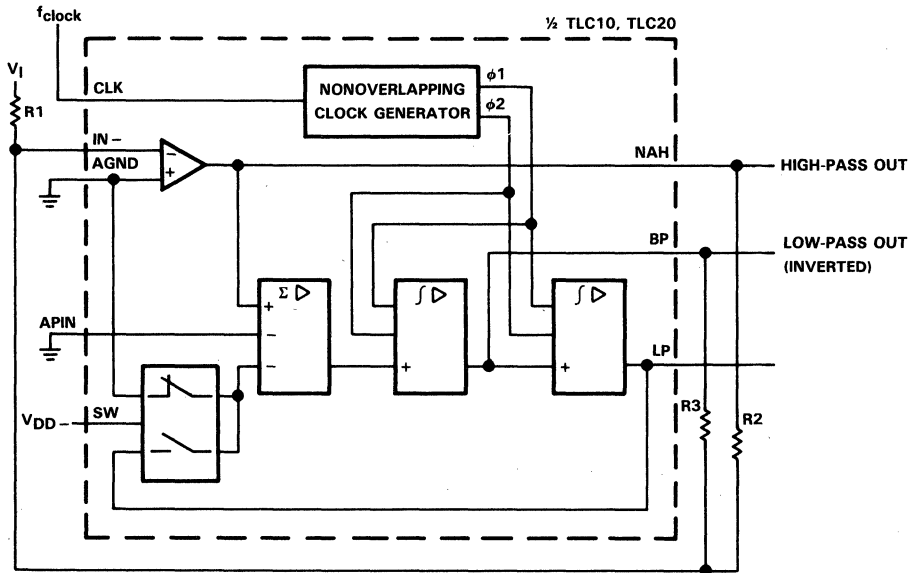

$$H_{OLP} = (R2 + R1)/(R2 + R4) \times R4/R1$$

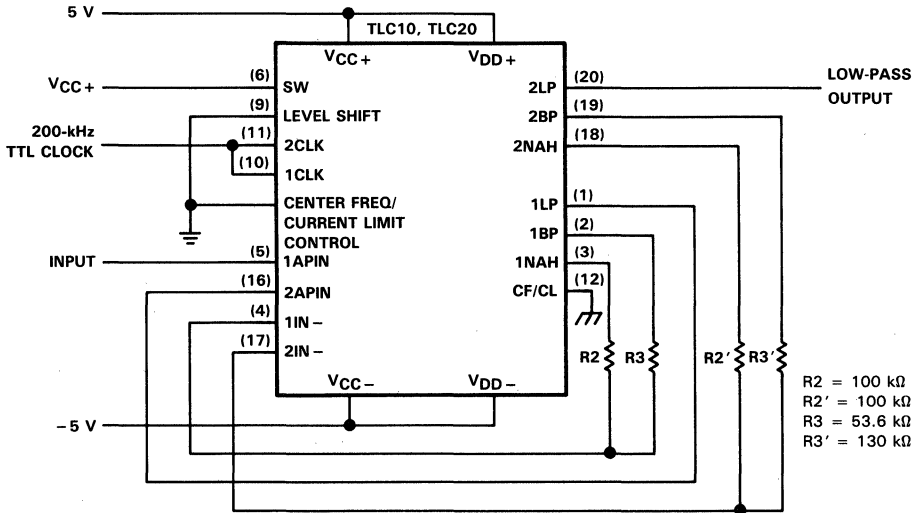

FIGURE 10. FOURTH-ORDER 2-kHz LOW-PASS BUTTERWORTH FILTER

filter terminology

- f_c The cutoff frequency of the low-pass or high-pass filter output
- f_{clock} The input clock frequency to the device
- f_{notch} The notch frequency of the notch output
- f_o The center frequency of the complex pole pair second-order function
- f_z The center frequency of the complex zero pair
- HOBP The band-pass output voltage gain (V/V) at the band-pass center frequency
- HOHP The high-pass output voltage gain (V/V) as the frequency approaches $0.5 f_{clock}$
- HOLP The low-pass output voltage gain (V/V) as the frequency approaches 0
- HON The notch output voltage gain (V/V) at the notch frequency
- HON1 The low-side notch output voltage gain as the frequency approaches 0
- HON2 The high-side notch output voltage gain as the frequency approaches $0.5 f_{clock}$
- HOZ1 Gain at complex zero output (as $f \rightarrow 0$ Hz)
- HOZ2 Gain at complex zero output (as f approaches $0.5 f_{clock}$)
- Q The quality factor of the complex pole pair second-order function. Q is the ratio of f_o to the 3-dB bandwidth of the band-pass output. The value of Q also affects the possible peaking of the low-pass and high-pass outputs.
- Q_z The quality factor of the complex zero pair, if such a complex pair exists. This parameter is used when an all-pass filter output is desired.

FIGURE 11. BAND-PASS OUTPUT

$$Q = \frac{f_o}{f_H - f_L}; f_o = \sqrt{f_L f_H}$$

$$f_L = f_o \left(\frac{-1}{2Q} + \sqrt{\left(\frac{1}{2Q}\right)^2 + 1} \right)$$

$$f_H = f_o \left(\frac{1}{2Q} + \sqrt{\left(\frac{1}{2Q}\right)^2 + 1} \right)$$

FIGURE 12. LOW-PASS OUTPUT

$$f_c = f_o \times \sqrt{\left(1 - \frac{1}{2Q^2}\right) + \sqrt{\left(1 - \frac{1}{2Q^2}\right)^2 + 1}}$$

$$f_p = f_o \sqrt{1 - \frac{1}{2Q^2}}$$

$$HOP = HOLP \times \frac{1}{\frac{1}{Q} \sqrt{1 - \frac{1}{4Q^2}}}$$

FIGURE 13. HIGH-PASS OUTPUT

$$f_c = f_o \times \left[\sqrt{\left(1 - \frac{1}{2Q^2}\right) + \sqrt{\left(1 - \frac{1}{2Q^2}\right)^2 + 1}} \right]^{-1}$$

$$f_p = f_o \times \left[\sqrt{1 - \frac{1}{2Q^2}} \right]^{-1}$$

$$HOP = HOHP \times \frac{1}{\frac{1}{Q} \sqrt{1 - \frac{1}{4Q^2}}}$$

- Three On-Chip 16-Bit Data Registers
- Software Compatible with Larger TL530 and TL531 (21-Input Versions)
- On-Chip Sample-and-Hold Circuit
- Single 5-V Supply Operation
- Low Power Consumption . . . 6.5 mW Typ
- Improved Direct Replacements for Texas Instruments TL532 and TL533, National Semiconductor ADC0829, and Motorola MC14442

description

The TLC532A and TLC533A are monolithic LinCMOSTM peripheral integrated circuits each designed to interface a microprocessor for analog data acquisition. These devices are complete peripheral data acquisition systems on a single chip and can convert analog signals to digital data from up to 11 external analog terminals. Each device features operation from a single 5-volt supply. Each contains a 12-channel analog multiplexer, an 8-bit ratiometric analog-to-digital (A/D) converter, a sample-and-hold, three 16-bit registers, and microprocessor-compatible control circuitry. Additional features include a built-in self-test, six multipurpose (analog or digital) inputs, five external analog inputs, and an 8-pin input/output (I/O) data port. The three on-chip data registers store the control data, the conversion results, and the input digital data that can be accessed via the microprocessor data bus in two 8-bit bytes (most-significant byte first). In this manner, a microprocessor can access up to 11 external analog inputs or 6 digital signals and the positive reference voltage that may be used for self-test.

TLC532AM, TLC532AI, TLC533AM, TLC533AI LinCMOS™ 8-BIT ANALOG-TO-DIGITAL PERIPHERALS WITH 5 ANALOG AND 6 DUAL-PURPOSE INPUTS

description (continued)

The A/D conversion uses the successive-approximation technique and switched-capacitor circuitry. This method eliminates the possibility of missing codes, nonmonotonicity, and a need for zero or full-scale adjustment. Any one of 11 analog inputs (or self-test) can be converted to an 8-bit digital word and stored in 10 microseconds (TLC532A) or 20 microseconds (TLC533A) after instructions from the microprocessor have been recognized. The on-chip sample-and-hold functions automatically to minimize errors due to noise on the analog inputs. Furthermore, differential high-impedance reference inputs are available to help isolate the analog circuitry from the logic and supply noises while easing ratiometric conversion and scaling.

The TLC532AM and TLC533AM are available in both the N and FN plastic packages and are characterized for operation from -55°C to 125°C . The TLC532AI and TLC533AI are characterized for operation from -40°C to 85°C .

functional description

The TLC532A and TLC533A provide direct interface to a microprocessor-based system. Control of the TLC532A and TLC533A is handled via the 8-line TTL-compatible 3-state data bus, the three control inputs (Read/Write, Register Select, and Chip Select), and the Clock input. Each device contains three 16-bit internal registers. These registers are the control register, the analog conversion data register, and the digital data register.

A high level at the Read/Write input and a low level at the Chip Select input set the device to output data on the 8-line data bus for the processor to read. A low level at the Read/Write input and a low level at the Chip Select input set the device to receive instructions into the internal control register on the 8-line data bus from the processor. When the device is in the read mode and the Register Select input is low, the processor will read the data contained in the analog conversion data register. However, when the Register Select input is high, the processor reads the data contained in the digital data register.

The control register is a write-only register into which the microprocessor writes command instructions for the device to start A/D conversion and to select the analog channel to be converted. The analog conversion data register is a read-only register that contains the current converter status and most recent conversion results. The digital data register is also a read-only register that holds the digital input logic levels from the six dual-purpose inputs.

Internally each device contains a byte pointer that selects the appropriate byte during two cycles of the Clock input in a normal 16-bit microprocessor instruction. The internal pointer will automatically point to the most-significant (MS) byte after the first complete clock cycle any time that the Chip Select is at the high level for at least one clock cycle. This causes the device to treat the next signal on the 8-line data bus as the MS byte. A low level at the Chip Select input activates the inputs and outputs and an internal function decoder. However, no data is transferred until the Clock goes high. The internal byte pointer first points to the MS byte of the selected register during the first clock cycle. After the first clock cycle in which the MS byte is accessed, the internal pointer switches to the LS byte and remains there for as long as Chip Select is low. The MS byte of any register may be accessed by either an 8-bit or a 16-bit microprocessor instruction; however, the LS byte may only be accessed by a 16-bit microprocessor instruction.

Normally, a two-byte word is written into or read from the controlling processor, but a single byte can be read by the processor by proper manipulation of the Chip Select input. This can be used to read conversion status from the analog conversion data register or the digital multipurpose input levels from the digital data register. The format and content of each two-byte word is shown in Figures 1 through 3.

TLC532AM, TLC532AI, TLC533AM, TLC533AI

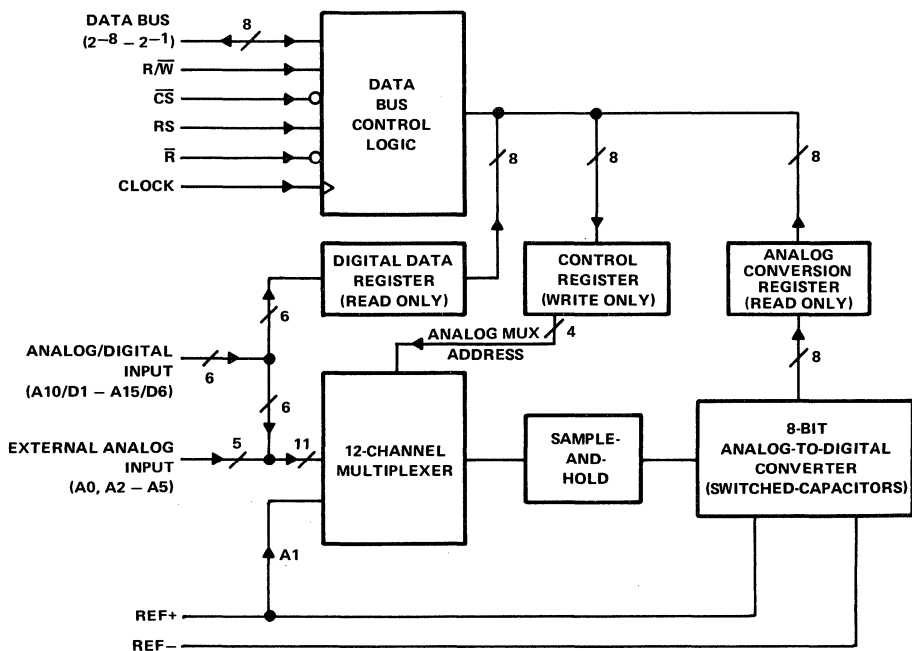

LinCMOS™ 8-BIT ANALOG-TO-DIGITAL PERIPHERALS WITH 5 ANALOG AND 6 DUAL-PURPOSE INPUTS

functional description (continued)

A conversion cycle is started after a two-byte instruction is written into the control register and the start conversion (SC) bit is a logic high. This two-byte instruction also selects the input analog channel to be converted. The status (EOC) bit in the analog conversion data register is reset and it remains reset until the conversion is completed, at that time the status bit is then set again. After conversion, the results are loaded into the analog conversion data register. These results remain in the analog conversion data register until the next conversion cycle is completed. If a new conversion command is entered into the control register while the conversion cycle is in progress, the on-going conversion will be aborted and a new channel acquisition cycle will immediately begin.

The Reset input allows the device to be externally forced to a known state. When a low level is applied to the Reset input for a minimum of three clock periods, the start conversion bit is cleared. The A/D converter is then idled and all the outputs are placed in the high-impedance off-state. However, the content of the analog conversion data register is not affected by the Reset input going to a low level.

Detailed information on interfacing to most popular microprocessors is readily available from the factory.

- NOTES:
- This is a 16-bit input instruction from the microprocessor being sent to the control data register.
 - This is the 2-byte (16-bit) content of the digital data register being sent to the microprocessor.
 - This is the LS byte (8-bit) content of the analog conversion data register being sent to the microprocessor.
 - This is the LS byte (8-bit) content of the digital data register being sent to the microprocessor.
 - These are MS byte (8-bit), LS byte (8-bit), and LS byte (8-bit) content of the analog conversion data register or digital data register being sent to the microprocessor.
 - This is the 2-byte (16-bit) content of the analog conversion data register being sent to the microprocessor.

TLC532AM, TLC532AI, TLC533AM, TLC533AI
 LinCMOS™ 8-BIT ANALOG-TO-DIGITAL PERIPHERALS
 WITH 5 ANALOG AND 6 DUAL-PURPOSE INPUTS

read or write cycle time sequence

- NOTES: A. The reset pulse (\bar{R} low) is required only during power-up.
 B. The most-significant byte output of Data Out occurs when CLK is high. When CLK is low, Data Out is in the high-impedance (off) state. When CLK goes high again, the least-significant byte is placed on the data bus. At this point, the least-significant byte will remain on the bus for as long as CLK is kept high.

TLC532AM, TLC532AI, TLC533AM, TLC533AI
LinCMOS™ 8-BIT ANALOG-TO-DIGITAL PERIPHERALS
WITH 5 ANALOG AND 6 DUAL-PURPOSE INPUTS

Unused Bits (X) – The MS byte bits 2-1 through 2-7 and LS byte bits 2-1 through 2-4 of the control register are not used internally.
 Start Conversion (SC) – When the SC bit in the MS byte is set to a logical 1 (high level), analog-to-digital conversion of the specified analog channel will begin immediately after the completion of the control register write.
 Analog Multiplexer Address (A0-A3) – These four address bits are decoded by the analog multiplexer and used to select the appropriate analog channel as shown below:

Hexadecimal Address (A3 = MSB)	Channel Select
0	A0
1	REF+ (A1)
2-5	A2-A5
6-9 (not used)	
A-F	A10-A15

FIGURE 1. CONTROL REGISTER TWO-BYTE WRITE WORD FORMAT AND CONTENT

A/D Status (EOC) – The A/D status end-of-conversion (EOC) bit is set whenever an analog-to-digital conversion is successfully completed by the A/D converter. The status bit is cleared by a 16-bit write from the microprocessor to the control register. The remainder of the bits in the MS byte of the analog conversion data register are always reset to logical 0 to simplify microprocessor interrogation of the A/D converter status.
 A/D Result (R0-R7) – The LS byte of the analog conversion data register contains the result of the analog-to-digital conversion. Result bit R7 is the MSB and the converter follows the standard convention of assigning a code of all ones (11111111) to a full-scale analog voltage. There are no special overflow or underflow indications.

FIGURE 2. ANALOG CONVERSION DATA REGISTER ONE-BYTE AND TWO-BYTE READ WORD FORMAT AND CONTENT

Shared Digital Port (A10/D1-A15/D6) – The voltage present on these pins is interpreted as a digital signal and the corresponding states are read from these bits. A digital value will be given for each pin even if some or all of these pins are being used as analog inputs.
 Analog Multiplexer Address (A0-A3) – The address of the selected analog channel presently addressed is given by these bits.
 Unused Bits (X) – LS byte bits 2-3 through 2-8 of the digital data register are not used.

	TLC__AI			-40			85	

NOTE 2: Analog input voltages greater than or equal to that applied to the REF+ terminal convert to all ones (11111111), while input voltages equal to or less than that applied to the REF- terminal convert to all zeros (00000000). For proper operation, the positive reference voltage, V_{REF+} , must be at least 1-volt greater than the negative reference voltage, V_{REF-} . In addition, unadjusted errors may increase as the differential reference voltage, $V_{REF+} - V_{REF-}$, falls below 4.75 volts.

I_{CC}	Supply current	$V_{CC} = 5.5$ V		1.4	2	mA	

NOTE 3: Analog input current is an average of the current flowing into a selected analog channel input during one full conversion cycle.

operating characteristics over recommended operating free-air temperature range, $V_{REF+} = V_{CC}$, V_{REF-} at ground, $f_{CLK} = 2$ MHz (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP†	MAX	UNIT
	Linearity error	See Note 4			± 0.5	LSB
	Zero error	See Note 5			± 0.5	LSB
	Full-scale error	See Note 5			± 0.5	LSB
	Total unadjusted error	See Note 6			± 0.5	LSB
	Absolute accuracy error	See Note 7			± 1	LSB
t_{conv}	Conversion time (including channel acquisition time)			30		Clock Cycles
t_{acq}	Channel acquisition time prior to starting conversion			10		Clock Cycles
t_{en}	Data output enable time (see Note 8)	$C_L = 50$ pF, $R_L = 3$ k Ω ,			250	ns
t_{dis}	Data output disable time	$C_L = 50$ pF, $R_L = 3$ k Ω		10		ns
$t_{r(bus)}$	Data bus output rise time	High-impedance to high-level	$C_L = 50$ pF, $R_L = 3$ k Ω		150	ns
		Low to high-level			300	
$t_{f(bus)}$	Data bus output fall time	High-impedance to low-level	$C_L = 50$ pF, $R_L = 3$ k Ω		150	ns
		High to low-level			300	

†Typical values are at $V_{CC} = 5$ V, $T_A = 25^\circ\text{C}$.

- NOTES:
- Linearity error is the deviation from the best straight line through the A/D transfer characteristics.
 - Zero error is the difference between 00000000 and the converted output for zero input voltage; full-scale error is the difference between 11111111 and the converted output for full-scale input voltage.
 - Total unadjusted error is the sum of linearity, zero, and full-scale errors.
 - Absolute accuracy error is the maximum difference between an analog value and the nominal midstep value within any step. This includes all errors including inherent quantization error, which is the ± 0.5 LSB uncertainty caused by the A/D converters finite resolution.
 - If chip-select setup time, $t_{su}(CS)$, is less than 0.14 microseconds, the effective data output enable time, t_{en} , may extend such that $t_{su}(CS) + t_{en}$ is equal to a maximum of 0.475 microseconds.

TLC540M, TLC540I, TLC541M, TLC541I LinCMOS™ 8-BIT ANALOG-TO-DIGITAL PERIPHERALS WITH SERIAL CONTROL AND 11 INPUTS

D2799, OCTOBER 1983—REVISED DECEMBER 1985

- LinCMOS™ Technology
- 8-Bit Resolution A/D Converter
- Microprocessor Peripheral or Stand-Alone Operation
- On-Chip 12-Channel Analog Multiplexer
- Built-In Self-Test Mode
- Software-Controllable Sample and Hold
- Total Unadjusted Error . . . ± 0.5 LSB Max
- TLC541 is Direct Replacement for Motorola MC145040 and National Semiconductor ADC0811. TLC540 is Capable of Higher Speed
- Pinout and Control Signals Compatible with TLC1540 Family of 10-Bit A/D Converters

TYPICAL PERFORMANCE	TLC540	TLC541
Channel Acquisition Sample Time	2 μ s	3.6 μ s
Conversion Time	9 μ s	17 μ s
Samples per Second	75 $\times 10^3$	40 $\times 10^3$
Power Dissipation	6 mW	6 mW

description

The TLC540 and TLC541 are LinCMOS™ A/D peripherals built around an 8-bit switched-capacitor successive-approximation A/D converter. They are designed for serial interface to a microprocessor or peripheral via a three-state output with up to four control inputs [including independent System Clock, I/O Clock, Chip Select (\overline{CS}), and Address Input]. A 4-megahertz system clock for the TLC540 and a 2.1-megahertz system clock for the TLC541 with a design that includes simultaneous read/write operation allow high-speed data transfers and sample rates of up to 75,180 samples per second for the TLC540 and 40,000 samples per second for the TLC541. In addition to the high-speed converter and versatile control logic, there is an on-chip 12-channel analog multiplexer that can be used to sample any one of 11 inputs or an internal "self-test" voltage, and a sample-and-hold that can operate automatically or under microprocessor control. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

The converters incorporated in the TLC540 and TLC541 feature differential high-impedance reference inputs that facilitate ratiometric conversion, scaling, and analog circuitry isolation from logic and supply noises. A switched-capacitor design allows guaranteed low-error (± 0.5 LSB) conversion in 9 microseconds for the TLC540 and 17 microseconds for the TLC541 over the full operating temperature range.

The TLC540 and the TLC541 are available in both the N and FN plastic packages. The M-suffix versions are characterized for operation from -55°C to 125°C . The I-suffix versions are characterized for operation from -40°C to 85°C .

functional block diagram

2

Data Acquisition Circuits

operating sequence

- NOTES: A. The conversion cycle, which requires 36 System Clock periods, is initiated on the 8th falling edge of the I/O Clock after \overline{CS} goes low for the channel whose address exists in memory at that time. If \overline{CS} is kept low during conversion, the I/O Clock must remain low for at least 36 System Clock cycles to allow conversion to be completed.
- B. The most significant bit (MSB) will automatically be placed on the DATA OUT bus after \overline{CS} is brought low. The remaining seven bits (A6-A0) will be clocked out on the first seven I/O Clock falling edges.
- C. To minimize errors caused by noise at the \overline{CS} input, the internal circuitry waits for three System Clock cycles (or less) after a chip select falling edge is detected before responding to control input signals. Therefore, no attempt should be made to clock-in address data until the minimum chip-select setup time has elapsed.

	TLC540I, TLC541I	-40	85	-40	85		

- NOTES: 2. Analog input voltages greater than that applied to REF+ convert as all '1's (11111111), while input voltages less than that applied to REF- convert as all '0's (00000000). For proper operation, REF+ voltage must be at least 1 volt higher than REF- voltage. Also, the total unadjusted error may increase as this differential reference voltage falls below 4.75 volts.
3. To minimize errors caused by noise at the chip select input, the internal circuitry waits for three System Clock cycles (or less) after a chip select falling edge is detected before responding to control input signals. Therefore, no attempt should be made to clock-in an address until the minimum chip select setup time has elapsed.
4. This is the time required for the clock input signal to fall from V_{IH} min to V_{IL} max or to rise from V_{IL} max to V_{IH} min. In the vicinity of normal room temperature, the devices function with input clock transition time as slow as 2 microseconds for remote data acquisition applications where the sensor and the A/D converter are placed several feet away from the controlling microprocessor.

principles of operation

The TLC540 and TLC541 are each complete data acquisition systems on a single chip. They include such functions as analog multiplexer, sample-and-hold, 8-bit A/D converter, data and control registers, and control logic. For flexibility and access speed, there are four control inputs [two clocks, chip select (\overline{CS}), and address]. These control inputs and a TTL-compatible 3-state output are intended for serial communications with a microprocessor or microcomputer. With judicious interface timing, with TLC540 a conversion can be completed in 9 microseconds, while complete input-conversion-output cycles can be repeated every 13 microseconds. With TLC541 a conversion can be completed in 17 microseconds, while complete input-conversion-output cycles are repeated every 25 microseconds. Furthermore, this fast conversion can be executed on any of 11 inputs or its built-in "self-test," and in any order desired by the controlling processor.

The System and I/O Clocks are normally used independently and do not require any special speed or phase relationships between them. This independence simplifies the hardware and software control tasks for the device. Once a clock signal within the specification range is applied to the System Clock input, the control hardware and software need only be concerned with addressing the desired analog channel, reading the previous conversion result, and starting the conversion by using the I/O Clock. The System Clock will drive the "conversion crunching" circuitry so that the control hardware and software need not be concerned with this task.

When \overline{CS} is high, the Data Output pin is in a three-state condition and the Address Input and I/O Clock pins are disabled. This feature allows each of these pins, with the exception of the \overline{CS} pin, to share a control logic point with their counterpart pins on additional A/D devices when additional TLC540/541 devices are used. In this way, the above feature serves to minimize the required control logic pins when using multiple A/D devices.

The control sequence has been designed to minimize the time and effort required to initiate conversion and obtain the conversion result. A normal control sequence is:

1. \overline{CS} is brought low. To minimize errors caused by noise at the \overline{CS} input, the internal circuitry waits for two rising edges and then a falling edge of the System Clock after a low \overline{CS} transition, before the low transition is recognized. This technique is used to protect the device against noise when the device is used in a noisy environment. The MSB of the previous conversion result will automatically appear on the Data Out pin.
2. A new positive-logic multiplexer address is shifted in on the first four rising edges of the I/O Clock. The MSB of the address is shifted in first. The negative edges of these four I/O clock pulses shift out the second, third, fourth, and fifth most significant bits of the previous conversion result. The on-chip sample-and-hold begins sampling the newly addressed analog input after the fourth falling edge. The sampling operation basically involves the charging of internal capacitors to the level of the analog input voltage.
3. Three clock cycles are then applied to the I/O pin and the sixth, seventh, and eighth conversion bits are shifted out on the negative edges of these clock cycles.
4. The final eighth clock cycle is applied to the I/O Clock pin. The falling edge of this clock cycle completes the analog sampling process and initiates the hold function. Conversion is then performed during the next 36 System Clock cycles. After this final I/O Clock cycle, \overline{CS} must go high or the I/O Clock must remain low for at least 36 System Clock cycles to allow for the conversion function.

\overline{CS} can be kept low during periods of multiple conversion. When keeping \overline{CS} low during periods of multiple conversion, special care must be exercised to prevent noise glitches on the I/O Clock line. If glitches occur on the I/O Clock line, the I/O sequence between the microprocessor/controller and the device will lose synchronization. Also, if \overline{CS} is taken high, it must remain high until the end of the conversion. Otherwise, a valid falling edge of \overline{CS} will cause a reset condition, which will abort the conversion in progress.

A new conversion may be started and the ongoing conversion simultaneously aborted by performing steps 1 through 4 before the 36 System Clock cycles occur. Such action will yield the conversion result of the previous conversion and not the ongoing conversion.

TLC540M, TLC540I, TLC541M, TLC541I LinCMOS™ 8-BIT ANALOG-TO-DIGITAL PERIPHERALS WITH SERIAL CONTROL AND 11 INPUTS

principles of operation (continued)

It is possible to connect the System and I/O Clock pins together in special situations in which controlling circuitry points must be minimized. In this case, the following special points must be considered in addition to the requirements of the normal control sequence previously described.

1. When \overline{CS} is recognized by the device to be at a low level, the common clock signal is used as an I/O Clock. When \overline{CS} is recognized by the device to be at a high level, the common clock signal is used to drive the "conversion crunching" circuitry.
2. The device will recognize a \overline{CS} low transition only when the \overline{CS} input changes and subsequently the System Clock pin receives two positive edges and then a negative edge. For this reason, after a \overline{CS} negative edge, the first two clock cycles will not shift in the address because a low \overline{CS} must be recognized before the I/O Clock can shift in an analog channel address. Also, upon shifting in the address, \overline{CS} must be raised after the sixth I/O Clock pulse that has been recognized by the device, so that a \overline{CS} low level will be recognized upon the lowering of the eighth I/O Clock signal that is recognized by the device. Otherwise, additional common clock cycles will be recognized as I/O Clock pulses and will shift in an erroneous address.

For certain applications, such as strobing applications, it is necessary to start conversion at a specific point in time. This device will accommodate these applications. Although the on-chip sample-and-hold begins sampling upon the negative edge of the fourth I/O Clock cycle, the hold function is not initiated until the negative edge of the eighth I/O Clock cycle. Thus, the control circuitry can leave the I/O Clock signal in its high state during the eighth I/O Clock cycle until the moment at which the analog signal must be converted. The TLC540/TLC541 will continue sampling the analog input until the eighth falling edge of the I/O Clock. The control circuitry or software will then immediately lower the I/O Clock signal and hold the analog signal at the desired point in time and start conversion.

Detailed information on interfacing to most popular microprocessors is readily available from the factory.

description

The TLC543 and TLC544 are LinCMOS™ A/D peripherals built around an 8-bit switched-capacitor successive-approximation A/D converter. They are designed for serial interface to a microprocessor or peripheral via a three-state output with up to four control lines that include I/O Clock, Chip Select (\overline{CS}), Address Input, and End-of-Conversion Output (EOC). A 4-megahertz on-chip system clock and simultaneous read/write operations permit high-speed data transfer and minimum sample rates of 45,500 cycles per second for TLC543 and 40,000 cycles for the TLC544. In addition to the high-speed converter and versatile control logic, there is an on-chip 6-channel analog multiplexer that can be used to sample any one of five inputs or an internal "self-test" voltage and a sample-and-hold that can operate automatically or under processor control.

The converters incorporated in the TLC543 and TLC544 feature differential high-impedance reference inputs that permit ratiometric conversion, scaling, and analog circuitry isolation from logic and supply noise.

A totally switched-capacitor design allows guaranteed low-error (± 0.5 LSB) conversion in 17 microseconds maximum for the TLC543 and the TLC544 over the full operating temperature range. The TLC543M and TLC544M are characterized for operation over the full military temperature range of -55°C to 125°C . The TLC543I and TLC544I are characterized for operation from -40°C to 85°C .

Data Acquisition Circuits

operating sequence

- NOTES:
- The conversion cycle, which requires 36 internal system clock periods, is initiated on the 8th falling edge of the I/O Clock after \overline{CS} goes low for the channel whose address exists in memory at that time. If \overline{CS} is kept low during conversion, the I/O clock must remain low for at least 36 system clock cycles to allow conversion to be completed.
 - The most significant bit (MSB) will automatically be placed on the DATA OUT bus after \overline{CS} is brought low. The remaining seven bits (A6-A0) will be clocked out on the first seven I/O Clock falling edges.
 - To minimize errors caused by noise at the \overline{CS} input, the internal circuitry waits for three internal system clock cycles (1.4 μ s at 2 MHz) after a chip select transition before responding to control input signals. Therefore, no attempt should be made to clock-in address data until the minimum chip-select setup time has elapsed.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

introduction

TLC543 and TLC544 are each complete data acquisition systems on a single chip. They include the functions of analog multiplexer, sample and hold, 8-bit A/D converter, data and control registers, and control logic. Flexible serial communication is achieved with a microprocessor or microcomputer using a TTL-compatible three-state Data Out and four control lines: Chip Select (\overline{CS}), I/O Clock, Address Input, and End of Conversion (EOC) output.

To maximize access speed, the device simultaneously writes the previous conversion result, reads a new multiplexer address, and acquires the analog signal. This is followed by the A/D conversion, whose end is signalled by EOC output going high. These Total Access and Conversion Cycles are completed in a minimum of 22 μ s for the TLC543 and 25 μ s for the TLC544. Conversion can take place, in any order, on the five analog inputs or the built-in self-test system.

The system clock, which drives the control logic and the switched-capacitor successive approximation A/D converter, is internal to the device and typically runs at a frequency of 4 MHz. This internal system clock runs independently and there are no required phase or frequency relationships with other signals.

digital interface

The I/O clock controls the acquisition of the analog signal as well as all serial data communications between the TLC543 or TLC544 and the host processor. This I/O clock from the host consists of a burst of eight pulses separated by the conversion time. Timing may be achieved by chip select (\overline{CS}) synchronously gating a continuous I/O clock or directly from the host with \overline{CS} held low continuously.

With \overline{CS} high, Data Out is in a high-impedance condition with the Address Input and I/O clock input disabled. This feature allows the interface pins, with the exception of \overline{CS} and EOC, to share a common bus with additional TLC543 or TLC544 devices or other members of the TLC543/544 family of devices.

typical operating sequence

Consider an access and conversion sequence where \overline{CS} is being used: \overline{CS} is brought low and recognized after the time out of the noise-rejection circuitry. The MSB of the previous conversion result appears at Data Out, whose three-state output is enabled. The MSB of the new multiplexer address should be present at the Address Input to conform with the setup time, $t_{SU}(A)$, requirements before the first rising edge of the I/O clock. The multiplexer address is shifted in on the first three rising edges of the I/O clock.

The first seven falling edges of I/O CLOCK shift out the remaining seven bits of the previous conversion on DATA OUT. The eighth I/O clock falling edge returns the MSB to the Data Out. Optimum serial transfer takes place with the bit streams being read on the rising edges of the I/O clock for the respective devices and Data Out and Address In lines.

At the fourth falling edge of the I/O clock, the on-chip sample and hold begins to acquire the newly addressed analog input and continues until the eighth (and final) falling edge. A hold function is initiated by the eighth I/O clock pulse falling edge. If it is desired to start the conversion at a specific point in time (or lengthen the acquisition time), the host processor may leave the eighth I/O clock pulse in the high state until the moment at which the analog signal must be sampled. After bringing the eighth I/O pulse low, the A/D function is performed in the next 36 internal system clock cycles.

In applications where \overline{CS} is held low continuously, the bursts of eight I/O clock pulses should be timed to be at least t_{conv} apart.

\overline{CS} input

To minimize bus contention caused by noise enabling the three-state Data Out, when the \overline{CS} input is brought low the device waits for two rising edges and a falling edge of the internal system clock before recognizing the \overline{CS} transition. Hence, the setup time $t_{SU}(\overline{CS})$ should be observed when using the \overline{CS} input. This applies also to a \overline{CS} high-to-low transition, except for disabling of DATA OUT, which goes into a high-impedance state immediately within the t_{dIS} specification (see Figure 3). If this interruption of \overline{CS} in the low state is less than 1.5 internal system clock cycles, and hence not recognized, DATA OUT will be immediately enabled with the return of \overline{CS} to the low state. DATA OUT becomes enabled after a \overline{CS} high-to-low transition in time t_{EN} (equivalent to $t_{SU}(\overline{CS})$ for this device, see Figure 3).

\overline{CS} can be brought high during a conversion without affecting the ongoing conversion but must remain high until the end of conversion. Otherwise, a \overline{CS} falling edge will cause a reset condition that will abort the conversion in progress. When a new access cycle is started, the previous conversion result will be output.

A new conversion may be restarted by toggling \overline{CS} high-to-low at least $t_{SU}(\overline{CS})$ before the eighth falling edge of the I/O clock. The ongoing access cycle will be aborted. Again, when a new access cycle is started, the previous conversion result will be output.

end of conversion output (EOC)

EOC goes low a propagation delay time $t_{PHL}(\text{EOC})$ after the 8th falling edge of the I/O clock, and goes high when conversion is complete. At this time the MSB is available at Data Out; however, if \overline{CS} is high it will be necessary to bring \overline{CS} low and wait for the \overline{CS} recognition time before Data Out is available, since Data Out is in a high-impedance state when \overline{CS} is high. Delay time $t_{d}(\text{EOC})$ of EOC to Data Out is a negative value of 4 internal system clock cycles less internal propagation delay, because the EOC signal is output after 40 internal system clock cycles whereas conversion is complete with data available after 36 cycles.

description

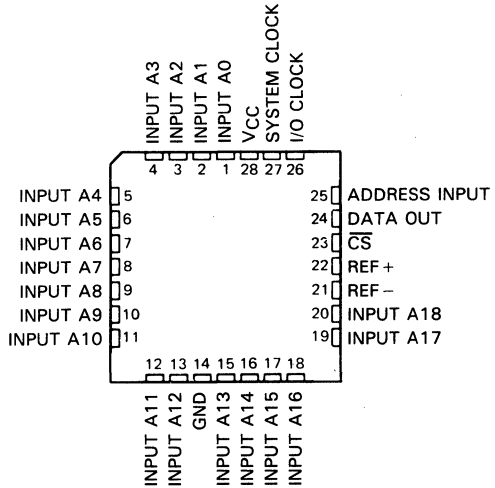

The TLC545 and TLC546 are LinCMOS™ A/D peripherals built around an 8-bit switched-capacitor successive-approximation A/D converter. They are designed for serial interface to a microprocessor or peripheral via a three-state output with up to four control inputs [including independent System Clock, I/O Clock, Chip Select (\overline{CS}), and Address Input]. A 4-megahertz system clock for the TLC545 and a 2.1-megahertz system clock for the TLC546 with a design that includes simultaneous read/write operation allow high-speed data transfers and sample rates of up to 76,923 samples per second for the TLC545, and 40,000 samples per second for the TLC546. In addition to the high-speed converter and versatile control logic, there is an on-chip 20-channel analog multiplexer that can be used to sample any one of 19 inputs or an internal "self-test" voltage, and a sample-and-hold that can operate automatically or under microprocessor control.

The converters incorporated in the TLC545 and TLC546 feature differential high-impedance reference inputs that facilitate ratiometric conversion, scaling, and analog circuitry isolation from logic and supply noises. A totally switched-capacitor design allows guaranteed low-error (± 0.5 LSB) conversion in 9 microseconds for

operating sequence

- NOTES:
- A. The conversion cycle, which requires 36 system clock periods, is initiated with the 8th I/O clock↓ after CS↓ for the channel whose address exists in memory at that time.
 - B. The most significant bit (MSB) will automatically be placed on the DATA OUT bus after CS is brought low. The remaining seven bits (A6-A0) will be clocked out on the first seven I/O clock falling edges.
 - C. To minimize errors caused by noise at the CS input, the internal circuitry waits for three system clock cycles (or less) after a chip select transition before responding to control input signals. Therefore, no attempt should be made to clock-in address data until the minimum chip-select setup time has elapsed.

ADVANCE INFORMATION

principles of operation

The TLC545 and TLC546 are both complete data acquisition systems on single chips. Each includes such functions as system clock, sample-and-hold, 8-bit A/D converter, data and control registers, and control logic. For flexibility and access speed, there are four control inputs; Chip Select (\overline{CS}), Address Input, I/O clock, and System clock. These control inputs and a TTL-compatible 3-state output facilitate serial communications with a microprocessor or microcomputer. The TLC545 and TLC546 can complete conversions in a maximum of 9 and 17 microseconds respectively, while complete input-conversion-output cycles can be repeated at a maximum of 13 and 25 microseconds, respectively.

The System and I/O clocks are normally used independently and do not require any special speed or phase relationships between them. This independence simplifies the hardware and software control tasks for the device. Once a clock signal within the specification range is applied to the System clock input, the control hardware and software need only be concerned with addressing the desired analog channel, reading the previous conversion result, and starting the conversion by using the I/O clock. The System clock will drive the "conversion crunching" circuitry so that the control hardware and software need not be concerned with this task.

When \overline{CS} is high, the Data Output pin is in a high-impedance condition, and the Address Input and I/O Clock pins are disabled. This feature allows each of these pins, with the exception of the \overline{CS} , to share a control logic point with their counterpart pins on additional A/D devices when additional TLC545/TLC546 devices are used. Thus, the above feature serves to minimize the required control logic pins when using multiple A/D devices.

The control sequence has been designed to minimize the time and effort required to initiate conversion and obtain the conversion result. A normal control sequence is:

1. \overline{CS} is brought low. To minimize errors caused by noise at the \overline{CS} input, the internal circuitry waits for two rising edges and then a falling edge of the System clock after a \overline{CS} transition before the transition is recognized. The MSB of the previous conversion result will automatically appear on the Data Out pin.
2. A new positive-logic multiplexer address is shifted in on the first five rising edges of the I/O clock. The MSB of the address is shifted in first. The negative edges of these five I/O clocks shift out the 2nd, 3rd, 4th, 5th, and 6th most significant bits of the previous conversion result. The on-chip sample-and hold begins sampling the newly addressed analog input after the 5th falling edge. The sampling operation basically involves the charging of internal capacitors to the level of the analog input voltage.
3. Two clock cycles are then applied to the I/O pin and the 7th and 8th conversion bits are shifted out on the negative edges of these clock cycles.
4. The final 8th clock cycle is applied to the I/O clock pin. The falling edge of this clock cycle completes the analog sampling process and initiates the hold function. Conversion is then performed during the next 36 system clock cycles. After this final I/O clock cycle, \overline{CS} must go high or the I/O clock must remain low for at least 36 system clock cycles to allow for the conversion function.

\overline{CS} can be kept low during periods of multiple conversion. When keeping \overline{CS} low during periods of multiple conversion, special care must be exercised to prevent noise glitches on the I/O Clock line. If glitches occur on the I/O Clock line, the I/O sequence between the microprocessor/controller and the device will lose synchronization. Also, if \overline{CS} is taken high, it must remain high until the end of conversion. Otherwise, a valid falling edge of \overline{CS} will cause a reset condition, which will abort the conversion in progress.

A new conversion may be started and the ongoing conversion simultaneously aborted by performing steps 1 through 4 before the 36 system clock cycles occur. Such action will yield the conversion result of the previous conversion and not the ongoing conversion.

It is possible to connect the system and I/O clocks together in special situations in which controlling circuitry points must be minimized. In this case, the following special points must be considered in addition to the requirements of the normal control sequence previously described.

1. When \overline{CS} is recognized by the device to be at a low level, the common clock signal is used as an I/O clock. When the \overline{CS} is recognized by the device to be at a high level, the common clock signal is used to drive the "conversion crunching" circuitry.
2. The device will recognize a \overline{CS} transition only when the \overline{CS} input changes and subsequently the system clock pin receives two positive edges and then a negative edge. For this reason, after a \overline{CS} negative edge, the first two clock cycles will not shift in the address because a low \overline{CS} must be recognized before the I/O clock can shift in an analog channel address. Also, upon shifting in the address, \overline{CS} must be raised after the 6th I/O clock, which has been recognized by the device, so that a \overline{CS} low level will be recognized upon the lowering of the 8th I/O clock signal recognized by the device. Otherwise, additional common clock cycles will be recognized as I/O clocks and will shift in an erroneous address.

For certain applications, such as strobing applications, it is necessary to start conversion at a specific point in time. This device will accommodate these applications. Although the on-chip sample-and-hold begins sampling upon the negative edge of the 5th I/O clock cycle, the hold function is not initiated until the negative edge of the 8th I/O clock cycle. Thus, the control circuitry can leave the I/O clock signal in its high state during the 8th I/O clock cycle, until the moment at which the analog signal must be converted. The TLC545/546 will continue sampling the analog input until the 8th falling edge of the I/O clock. The control circuitry or software must then immediately lower the I/O clock signal to initiate the hold function at the desired point in time and to start conversion.

Detailed information on interfacing to most popular microprocessors is readily available from the factory.

Data Acquisition Circuits

description

The TLC548 and TLC549 are LinCMOSTM A/D peripheral integrated circuits built around an 8-bit switched-capacitor successive-approximation ADC. They are designed for serial interface with a microprocessor or peripheral through a 3-state data output and an analog input. The TLC548 and TLC549 use only the Input/Output Clock (I/O Clock) input along with the Chip Select (\overline{CS}) input for data control. The maximum I/O clock input frequency of the TLC548 is guaranteed up to 2.048 megahertz, and the I/O clock input frequency of the TLC549 is guaranteed to 1.1 megahertz. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

Operation of the TLC548 and the TLC549 is very similar to that of the more complex TLC540 and TLC541 devices; however, the TLC548 and TLC549 provide an on-chip system clock that operates typically at 4 megahertz and requires no external components. The on-chip system clock allows internal device operation to proceed independently of serial input/output data timing and permits manipulation of the TLC548 and TLC549 as desired for a wide range of software and hardware requirements. The I/O Clock together with the internal system clock allow high-speed data transfer and conversion rates of 45,500 conversions per second for the TLC548, and 40,000 conversions per second for the TLC549.

Additional TLC548 and TLC549 features include versatile control logic, an on-chip sample-and-hold circuit that can operate automatically or under microprocessor control, and a high-speed converter with differential high-impedance reference voltage inputs that ease ratiometric conversion, scaling, and circuit isolation from logic and supply noises. Design of the totally switched-capacitor successive-approximation converter circuit allows conversion with a maximum total error of ± 0.5 least significant bit (LSB) in less than 17 microseconds.

The TLC548M and TLC549M are available in the D or P plastic package and are characterized for operation over the temperature range of -55°C to 125°C . The TLC548I and TLC549I are characterized for operation from -40°C to 85°C . The TLC548C and TLC549C are characterized for operation from 0°C to 70°C .

- NOTES: 3. Analog input voltages greater than that applied to REF+ convert to all ones (11111111), while input voltages less than that applied to REF- convert to all zeros (00000000). For proper operation, the positive reference voltage V_{REF+} must be at least 1 volt greater than the negative reference voltage V_{REF-} . In addition, unadjusted errors may increase as the differential reference voltage $V_{REF+} - V_{REF-}$ falls below 4.75 V.
4. This is the time required for the input/output clock input signal to fall from V_{IH} min to V_{IL} max or to rise from V_{IL} max to V_{IH} min. In the vicinity of normal room temperature, the devices function with input clock transition time as slow as 2 μ s for remote data acquisition applications in which the sensor and the ADC are placed several feet away from the controlling microprocessor.
5. To minimize errors caused by noise at the \overline{CS} input, the internal circuitry waits for two rising edges and one falling edge of internal system clock after $\overline{CS}\downarrow$ before responding to control input signals. This \overline{CS} set-up time is given by the $t_{\overline{CS}\uparrow}$ and $t_{su(CS)}$ specifications.

- NOTES: A. $C_L = 50$ pF for TLC548 and 100 pF for TLC549; C_L includes jig capacitance.
 B. $t_{en} = t_{pZH}$ or t_{pZL} , $t_{dis} = t_{pHZ}$ or t_{pLZ} .
 C. Waveform 1 is for an output with internal conditions such that the output is low except when disabled by the output control. Waveform 2 is for an output with internal conditions such that the output is high except when disabled by the output control.

TLC548, TLC549

LinCMOS™ 8-BIT ANALOG-TO-DIGITAL PERIPHERAL WITH SERIAL CONTROL

PRINCIPLES OF OPERATION

2

Data Acquisition Circuits

The TLC548 and TLC549 are each complete data acquisition systems on a single chip. Each contains an internal system clock, sample-and-hold, 8-bit A/D converter, data register, and control logic circuitry. For flexibility and access speed, there are two control inputs: I/O Clock and Chip Select (\overline{CS}). These control inputs and a TTL-compatible three-state output facilitate serial communications with a microprocessor or minicomputer. A conversion can be completed in 17 microseconds or less, while complete input-conversion-output cycles can be repeated in 22 microseconds for the TLC548 and in 25 microseconds for the TLC549.

The internal system clock and I/O clock are used independently and do not require any special speed or phase relationships between them. This independence simplifies the hardware and software control tasks for the device. Due to this independence and the internal generation of the system clock, the control hardware and software need only be concerned with reading the previous conversion result and starting the conversion by using the I/O clock. In this manner, the internal system clock drives the "conversion crunching" circuitry so that the control hardware and software need not be concerned with this task.

When \overline{CS} is high, the data output pin is in a high-impedance condition and the I/O clock pin is disabled. This \overline{CS} control function allows the I/O Clock pin to share the same control logic point with its counterpart pin when additional TLC548 and TLC549 devices are used. This also serves to minimize the required control logic pins when using multiple TLC548 and TLC549 devices.

The control sequence has been designed to minimize the time and effort required to initiate conversion and obtain the conversion result. A normal control sequence is:

1. \overline{CS} is brought low. To minimize errors caused by noise at the \overline{CS} input, the internal circuitry waits for two rising edges and then a falling edge of the internal system clock after a $\overline{CS}\downarrow$ before the transition is recognized. However, upon a \overline{CS} rising edge, DATA OUT will go to a high-impedance state within the t_{dis} specification even though the rest of the IC's circuitry will not recognize the transition until the $t_{su}(\overline{CS})$ specification has elapsed. This technique is used to protect the device against noise when used in a noisy environment. The most significant bit (MSB) of the previous conversion result will initially appear on the DATA OUT pin when \overline{CS} goes low.
2. The falling edges of the first four I/O clock cycles shift out the 2nd, 3rd, 4th, and 5th most significant bits of the previous conversion result. The on-chip sample-and-hold begins sampling the analog input after the 4th high-to-low transition of the I/O Clock. The sampling operation basically involves the charging of internal capacitors to the level of the analog input voltage.
3. Three more I/O clock cycles are then applied to the I/O pin and the 6th, 7th, and 8th conversion bits are shifted out on the falling edges of these clock cycles.
4. The final, (the 8th), clock cycle is applied to the I/O clock pin. The on-chip sample-and-hold begins the hold function upon the high-to-low transition of this clock cycle. The hold function will continue for the next four internal system clock cycles, after which the holding function terminates and the conversion is performed during the next 32 system clock cycles, giving a total of 36 cycles. After the 8th I/O clock cycle, \overline{CS} must go high or the I/O clock must remain low for at least 36 internal system clock cycles to allow for the completion of the hold and conversion functions. \overline{CS} can be kept low during periods of multiple conversion. When keeping \overline{CS} low during periods of multiple conversion, special care must be exercised to prevent noise glitches on the I/O Clock line. If glitches occur on the I/O Clock line, the I/O sequence between the microprocessor/controller and the device will lose synchronization. If \overline{CS} is taken high, it must remain high until the end of conversion. Otherwise, a valid high-to-low transition of \overline{CS} will cause a reset condition, which will abort the conversion in progress.

A new conversion may be started and the ongoing conversion simultaneously aborted by performing steps 1 through 4 before the 36 internal system clock cycles occur. Such action will yield the conversion result of the previous conversion and not the ongoing conversion.

PRINCIPLES OF OPERATION

For certain applications, such as strobing applications, it is necessary to start conversion at a specific point in time. This device will accommodate these applications. Although the on-chip sample-and-hold begins sampling upon the high-to-low transition of the 4th I/O clock cycle, the hold function does not begin until the high-to-low transition of the 8th I/O clock cycle, which should occur at the moment when the analog signal must be converted. The TLC548 and TLC549 will continue sampling the analog input until the high-to-low transition of the 8th I/O clock pulse. The control circuitry or software will then immediately lower the I/O clock signal and start the holding function to hold the analog signal at the desired point in time and start conversion.

Detailed information on interfacing to the most popular microprocessor is readily available from Texas Instruments.

description

The TLC1205 and TLC1225 converters are manufactured with Texas Instruments highly efficient **ADVANCED LinCMOS™** technology. Either of the TLC1205 or TLC1225 CMOS analog-to digital converters can be operated as a unipolar or bipolar converter. A unipolar input (0 to 5 V) can be accommodated with a single 5-volt supply, while a bipolar input (-5 V to 5 V) requires the addition of a 5-volt negative supply. Conversion is performed via the successive-approximation method. The 24-pin TLC1205 outputs the converted data in two 8-bit bytes, while the TLC1225 outputs the converted data in a parallel word and interfaces directly to a 16-bit data bus. Negative numbers are given in the 2's complement data format. All digital signals are fully TTL and CMOS compatible.

These converters utilize a self-calibration technique by which seven of the internal capacitors in the capacitive ladder of the A/D conversion circuitry can be automatically or manually calibrated. If the converters are operated in Mode 1, one of the seven internal capacitors is calibrated during the first part of the conversion sequence. For example, one capacitor is calibrated during the first conversion. The next capacitor is calibrated during the second conversion. If the converters are operated in Mode 2, the internal capacitors are calibrated during a nonconversion, capacitor-calibrate cycle in which all seven of the internal capacitors are calibrated at the same time. A Mode 2 conversion requires only 10 μs (2.6 MHz clock) after the nonconversion, capacitor-calibrating cycle has been completed. The calibration or conversion cycle may be initiated at any time by issuing the proper address to the data bus. The self-calibrating techniques eliminate the need for expensive trimming of thin-film resistors at the factory and provide excellent performance at low cost.

Data Acquisition Circuits

In Mode 1, these converters are replacements for National Semiconductor ADC1205 and ADC1225 integrated circuits. The Mode 1 conversion time for guaranteed accuracy is 51 clock cycles. In the Mode 2 operation, these devices are no longer true replacements. However, the Mode 2 conversion time for guaranteed accuracy is only 26 clock cycles.

The TLC1205AM, TLC1205BM, TLC1225AM, and TLC1225BM are characterized for operation over the full military temperature range of -55°C to 125°C . The TLC1205AI, TLC1205BI, TLC1225AI, and TLC1225BI are characterized for operation from -40°C to 85°C .

PRODUCT PREVIEW

operation description

calibration of comparator offset

The following actions are performed to calibrate the comparator offset:

1. The IN+ and IN- inputs are internally shorted together in order that the comparator input is zero. A course comparator offset calibration is performed by storing the offset voltages of the interconnecting comparator stages on the coupling capacitors, which connect the interconnecting stages. Refer to Figure 1. The storage of offset voltages is accomplished by closing all switches and then opening switches A and A', then switches B and B', and then C and C'. This process continues until all interconnecting stages of the comparator are calibrated. After this action, some of the comparator offset still remains uncalibrated.

FIGURE 1

2. An A/D conversion is done on the remaining offset with the 8-bit calibration DACs and 8-bit SAR and the result is stored in the RAM.

capacitor calibration of the ADC's Capacitive Ladder

The following actions are performed to calibrate capacitors in the 13-bit DAC's, which comprise the ADC's capacitive ladder:

1. The IN+ and IN- inputs are internally disconnected from the 13-bit capacitive DACs.
2. The most-significant-bit (MSB) capacitor is tied to REF, while the rest of the ladder capacitors are tied to GND. The A/D conversion result for the remaining comparator offset, obtained in step 2 above, is retrieved from the RAM and is input to the 8-bit DACs.
3. Step 1 of the Calibration of Comparator Offset sequence is performed. The 8-bit DAC input is returned to zero and the remaining comparator offset is then subtracted. Thus, the comparator offset is completely corrected.
4. Now the MSB capacitor is tied to GND, while the rest of the ladder capacitors, C_x , are tied to REF. An MSB capacitor voltage error (see Figure 2) on the comparator output will occur if the MSB capacitor does not equal the sum of the other capacitors in the capacitive ladder. This error voltage is converted to an 8-bit word from which a capacitor error is computed and stored in the RAM.
5. The capacitor voltage error for the next most significant capacitor is calibrated by keeping the MSB capacitor grounded and then performing the above Steps 1 - 4 while using the next most significant capacitor in lieu of the MSB capacitor. The seven most significant capacitors can be calibrated in this manner.

FIGURE 2

analog-to-digital conversion

The following steps are performed in the analog-to-digital conversion process:

1. Step 1 of the Calibration of Comparator Offset Sequence is performed. The A/D conversion result for the remaining comparator offset, which was obtained in Step 2 of the Calibration of Comparator Offset, is retrieved from the RAM and is input to the 8-bit DACs. Thus the comparator offset is completely corrected.
2. IN+ and IN- are sampled onto the 13-bit capacitive ladders.
3. The 13-bit analog-to-digital conversion is performed. As the successive-approximation conversion proceeds successively through the seven most significant capacitors, the error for each of these capacitors is recovered from the RAM and accumulated in a register. This register controls the 8-bit DACs so the total accumulated error for these capacitors is subtracted out during the conversion process.

Data Acquisition Circuits

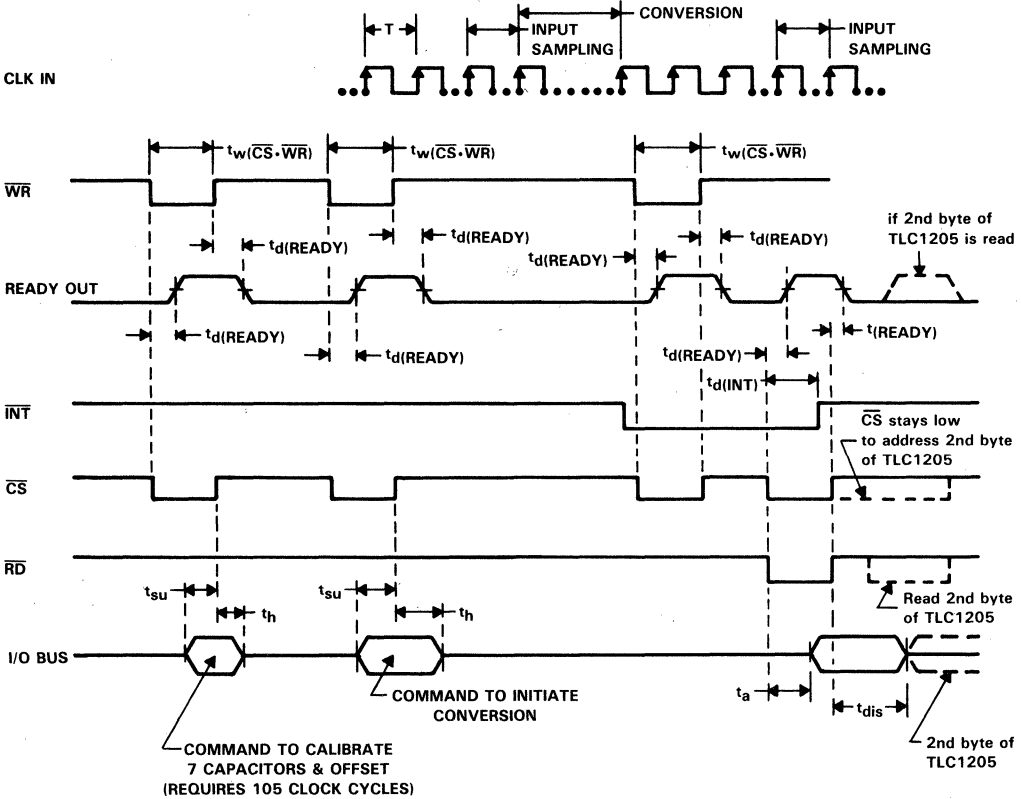

FIGURE 4. MODE 2 TIMING DIAGRAM

PARAMETER MEASUREMENT INFORMATION

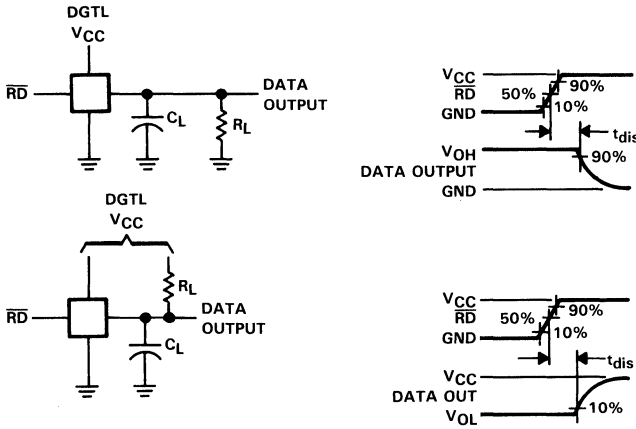

FIGURE 5. LOAD CIRCUITS AND WAVEFORMS

PRINCIPLES OF OPERATION

The following information is categorized into Mode 1 and Mode 2 groupings to allow the designer to concentrate on a particular mode of interest

power-up calibration sequence

Mode 1

When the chip is powered-up, the internal capacitors are automatically calibrated as part of the power-up sequence. This initial calibration sequence requires 105 clock cycles. The chip will not perform an A/D conversion during this calibration sequence.

Mode 2

Power-Up calibration is not automatic and calibration is initiated by writing control words to the six least significant bits of the data bus. If addressed or initiated, conversion can begin after the first clock cycle. However, full A/D conversion accuracy is not guaranteed until after internal capacitor calibration.

conversion start sequence

Mode 1

The conversion sequence is initiated when \overline{CS} and \overline{WR} are both low.

Mode 2

The writing of the conversion command word to the six least significant bits of the data bus, when either \overline{CS} or \overline{WR} goes high, initiates the conversion sequence.

analog sampling sequence

Mode 1

Sampling of the input signal occurs during clock cycles 29 thru 35 of the conversion sequence.

Mode 2

Sampling of the input signal occurs during clock cycles 4 thru 10 of the conversion sequence.

completed A/D conversion

When \overline{INT} goes low, conversion is complete and the A/D result can be read. A new conversion can begin immediately.

Mode 1

The A/D conversion is complete at the end of clock cycle 51 of the conversion sequence.

Mode 2

The A/D conversion is complete at the end of clock cycle 26 of the conversion sequence.

aborting a conversion in process and beginning a new conversion

Mode 1 and Mode 2

If a conversion is initiated while a conversion sequence is in process, the ongoing conversion will be aborted and a new conversion sequence will begin.

Mode 1

If the new conversion is started before the Analog Sampling begins (see Analog Sampling Sequence section and the Mode 1 Timing Diagram), the particular internal capacitor that was being calibrated during the aborted conversion sequence will be calibrated during the new conversion sequence. Otherwise, the next internal capacitor will be calibrated during the new conversion sequence.

reading the conversion result

TLC1205

Upon activating the required control signals to read the conversion result or status information, the appropriate pins are brought out of a high-impedance state and drive the data bus with the proper information. These pins are D12/D7/O through D8/D0/INT/DIO.

If \overline{STATUS} , \overline{CS} , and \overline{RD} are all low, status information can be read. The format of the conversion result and status information and the respective pins for output are presented in Table 1.

**TLC1205A, TLC1205B, TLC1225A, TLC1225B
SELF-CALIBRATING 12-BIT-PLUS-SIGN UNIPOLAR OR BIPOLAR
ANALOG-TO-DIGITAL CONVERTERS**

TABLE 1

BYTES	STATUS	CS	RD	I/O BUS							
				D12/ D7/	D12/ D6/	D12/ D5/	D12/ D4/	D11/ D3/	D10/ D2/	D9/ D1/	D8/ D0/
				0	SARS	0/	0/	0/	BYST/	EOC/	INT/
MSB	H	L	L	D12	D12	D12	D12	D11	D10	D9	D8
LSB	H	L	↑↓	D7	D6	D5	D4	D3	D2	D1	D0
STATUS	L	L	L	L	SARS	L	L	L	BYST	EOC	INT

The status information is described in Table 2.

TABLE 2

STATUS BIT	BIT DESCRIPTION	TO CLEAR BIT
L	The output has no meaning and is low.	
SARS	A high indicates that conversion is in progress.	
BYST	A low indicates that the next conversion result read will be the most significant conversion byte. A high indicates that the next conversion result read will be the least significant conversion byte. The BYST bit is toggled by reading the conversion result bytes. This bit can be cleared with a "status write" instruction.	By a "status write" or toggled by reading a conversion data byte
EOC	A high indicates that conversion is complete and the conversion data has been transferred to the output latch.	
INT	A high indicates that conversion is complete and the conversion data has been transferred to the output latch and is ready to read.	By reading a conversion data byte, reading the status byte, or a "status write"

With STATUS high, when CS and RD both go low, the most significant byte (MSB) of the conversion result can be read. Then by taking RD high and back low, the least significant byte (LSB) of the conversion result can be read. Subsequently taking RD high and low causes the alternate reading of the MSB and LSB of the conversion result.

The format of the output is extended sign with 2's complement, right justified data. For both unipolar and bipolar cases, the sign bit D12 is low if $V_{I+} - V_{I-}$ is positive and high if $V_{I+} - V_{I-}$ is negative. The format of the conversion result and the respective output pins are presented in Table 2. The format of the conversion result and the respective pins for output are presented in Table 1.

TLC1225

When both CS and RD go low, all 13 bits of conversion data are output to the I/O bus. The format of the output is extended sign with 2's complement, right justified data. Unlike the TLC1205, the TLC1225 does not have internal status information or a STATUS pin. For both unipolar and bipolar cases, the sign bit D12 is low if $V_{I+} - V_{I-}$ is positive and high if $V_{I+} - V_{I-}$ is negative.

general

reset INT

When reading the conversion data, the falling edge of the first low-going combination of \overline{CS} and \overline{RD} will reset \overline{INT} . The falling edge of the low-going combination of \overline{CS} and \overline{WR} will also reset \overline{INT} .

ready out

For high-speed microprocessors, READY OUT allows the TLC1205 and the TLC1225 to insert a wait state in the microprocessor's read cycle.

status write (TLC1205)

A status write resets the internal logic and status bits and aborts any conversion in process. A status write occurs when \overline{CS} , \overline{WR} , and STATUS are taken low.

reference voltage (V_{ref})

This voltage defines the range for $|V_{I+} - V_{I-}|$. When $|V_{I+} - V_{I-}|$ equals V_{ref} , the highest conversion data value results. When $|V_{I+} - V_{I-}|$ equals 0, the conversion data value is zero. Thus, for a given input, the conversion data changes ratiometrically with changes in V_{ref} .

Vos

This pin is a digital input and is used to select Mode 1 or Mode 2 operation. A logic low selects Mode 1; a logic high selects Mode 2.

In Mode 1, the ICs are true replacements for National Semiconductor's ADC1205 and ADC1225. The ADC1205 and ADC1225 use the VOS pin to adjust zero error. Since the zero error adjustment voltage is below the TLC1205's and TLC1225's maximum acceptable level for a logic low signal, the TLC1205 and TLC1225 ICs are true replacements. Even in Mode 1, the TLC1205's and TLC1225's converted data can be read earlier than the ADC1205's and ADC1225's.

calibration and conversion considerations

Mode 1

Calibration of the seven internal capacitors is an integral part of the A/D conversion. One of the seven internal capacitors is calibrated during the first part of the conversion sequence. For example, one of the capacitors is calibrated during the first conversion. The next capacitor is calibrated during the second conversion. After seven conversions, the pattern for calibrating the internal capacitors repeats. A conversion sequence requires 51 clock cycles.

A conversion is initiated by the low-going combination of \overline{CS} and \overline{WR} . The conversion sequence is illustrated in the Mode 1 timing diagram.

Mode 2

Calibration of the internal capacitor and A/D conversion are two separate actions. Each action is independently initiated. Mode 2 conversion is much faster than Mode 1, since Mode 2 conversion is not accompanied by the calibration of internal capacitors. In Mode 2, a calibration command that calibrates all seven internal capacitors is normally issued first. A conversion command then initiates the A/D conversion without calibrating the internal capacitors. Subsequent conversions can be performed by issuing additional conversion commands. The calibration and conversion commands are totally independent from one another and can be initiated in any order. Calibration and conversion commands require 105 and 26 clock cycles, respectively.

The calibrate and conversion commands are initiated by writing control words on the six least significant bits of the data bus. These control words are written into the IC when either \overline{CS} or \overline{WR} goes high. The initiation of these commands is illustrated in the Mode 2 Timing Diagram. The bit patterns for the commands are shown in Table 3.

TABLE 3. MODE 2 CONVERSION COMMANDS

COMMAND	$\overline{CS} + \overline{WR}$	I/O BUS						Required number of clock cycles
		DI5	DI4	DI3	DI2	DI1	DI0	
Conversion	↑	H	L	X	X	X	L	26
Calibrate†	↑	L	X	L	L	L	L	105

† Calibration is lost when clock is stopped.

analog inputs

differential inputs provide common mode rejection

The differential inputs reduce common-mode noise. Common-mode noise is noise common to both $IN+$ and $IN-$ inputs, such as 60-Hz noise. There is no time interval between the sampling of the $IN+$ and $IN-$ so these inputs are truly differential. Thus, no conversion errors result from a time interval between the sampling of the $IN+$ and $IN-$ inputs.

input bypass capacitors

Input bypass capacitors may be used for noise filtering. However, the charge on these bypass capacitors will be depleted during the input sampling sequence when the internal sampling capacitors are charged. Note that the charging of the bypass capacitors through the differential source resistances must keep pace with the charge depletion of the bypass capacitors during the input sampling sequence. Note that higher source resistances reduce the amount of charging current for the bypass capacitors. Also, note that fast, successive conversion will have the greatest charge depletion effect on the bypass capacitors. Therefore, the above phenomenon becomes more significant as source resistances and the conversion rate (i.e., higher clock frequency and conversion initiation rate) increase.

In addition, if the above phenomenon prevents the bypass capacitors from fully charging between conversions, voltage drops across the source resistances will result due to the ongoing bypass capacitor charging currents. The voltage drops will cause a conversion error. Also, the voltage drops increase with higher $|V_{I+} - V_{I-}|$ values, higher source resistances, and lower charge on the bypass capacitors (i.e., faster conversion rate).

For low-source-resistance applications ($R_{source} < 100 \Omega$), a 0.001- μF bypass capacitor at the inputs will prevent pickup due to the series lead inductance of a long wire. A 100-ohm resistor can be placed between the capacitor and the output of an operational amplifier to isolate the capacitor from the operational amplifier.

input leads

The input leads should be kept as short as possible, since the coupling of noise and digital clock signals to the inputs can cause errors.

power supply considerations

Noise spikes on the V_{CC} lines can cause conversion error. Low-inductance tantalum capacitors ($> 1 \mu F$) with short leads should be used to bypass ANLG V_{CC} and DGTL V_{CC} . A separate regulator for the TLC1205 or TLC1225 and other analog circuitry will greatly reduce digital noise on the supply line.

positive and negative full-scale adjustment

2

Data Acquisition Circuits

unipolar inputs

Apply a differential input voltage that is 0.5 LSB below the desired analog full-scale voltage (V_{FS}) and adjust the magnitude of the REF input so that the output code is just changing from 0 1111 1111 1110 to 0 1111 1111 1111. If this transition is desired for a different input voltage, the reference voltage can be adjusted accordingly.

bipolar inputs

First, follow the procedure for the Unipolar case.

Second, apply a differential input voltage so that the digital output code is just changing from 1 0000 0000 0001 to 1 0000 0000 0000. Call this actual differential voltage V_X . The ideal differential voltage for this transition is:

$$-V_{FS} + \frac{V_{FS}}{8192} \quad (1)$$

The difference between the actual and ideal differential voltages is:

$$\Delta = V_X - \left(-V_{FS} + \frac{V_{FS}}{8192}\right) \quad (2)$$

Then apply a differential input voltage of:

$$V_X - \frac{\Delta}{2} \quad (3)$$

and adjust V_{REF} so the digital output code is just changing from 1 0000 0000 0001 to 1 0000 0000 0000. This procedure produces positive and negative full-scale transitions with symmetrical minimum error.

description

The TLC1540 and TLC1541 are LinCMOS™ A/D peripherals built around an 10-bit switched-capacitor successive-approximation A/D converter. They are designed for serial interface to a microprocessor or peripheral via a three-state output with up to four control inputs [including independent System Clock, I/O Clock, Chip Select (CS), and Address Input]. A 2.1-megahertz system clock for the TLC1540 and TLC1541, with a design that includes simultaneous read/write operation, allows high-speed data transfers and sample rates of up to 32,258 samples per second. In addition to the high-speed converter and versatile control logic, there is an on-chip 12-channel analog multiplexer that can be used to sample any one of 11 inputs or an internal "self-test" voltage, and a sample-and-hold that can operate automatically or under microprocessor control. Detailed information on interfacing to most popular microprocessors is readily available from the factory.

The converters incorporated in the TLC1540 and TLC1541 feature differential high-impedance reference inputs that facilitate ratiometric conversion, scaling, and analog circuitry isolation from logic and supply noises. A totally switched-capacitor design allows guaranteed low-error conversion (± 0.5 LSB for the TLC1540, ± 1 LSB for the TLC1541) in 21 microseconds over the full operating temperature range.

The TLC1540 and the TLC1541 are available in both the N and FN plastic packages. The M-suffix versions are characterized for operation from -55°C to 125°C . The I-suffix versions are characterized for operation from -40°C to 85°C .

Data Acquisition Circuits

operating sequence

- NOTES:
- The conversion cycle, which requires 44 System Clock periods, is initiated on the 10th falling edge of the I/O Clock! after \overline{CS} goes low for the channel whose address exists in memory at that time. If \overline{CS} is kept low during conversion, the I/O Clock must remain low for at least 44 System Clock cycles to allow conversion to be completed.
 - The most significant bit (MSB) will automatically be placed on the DATA OUT bus after \overline{CS} is brought low. The remaining nine bits (A8-A0) will be clocked out on the first nine I/O Clock falling edges.
 - To minimize errors caused by noise at the CS input, the internal circuitry waits for three System Clock cycles (or less) after a chip-select falling edge is detected before responding to control input signals. Therefore, no attempt should be made to clock-in address data until the minimum chip-select setup time has elapsed.

- NOTES: 2. Analog input voltages greater than that applied to REF+ convert as all "1"s (11111111), while input voltages less than that applied to REF- convert as all "0"s (00000000). For proper operation, REF+ voltage must be at least 1 volt higher than REF- voltage. Also, the total unadjusted error may increase as this differential reference voltage falls below 4.75 volts.
3. To minimize errors caused by noise at the chip select input, the internal circuitry waits for three System Clock cycles (or less) after a chip select falling edge is detected before responding to control input signals. Therefore, no attempt should be made to clock-in an address until the minimum chip select setup time has elapsed.
4. This is the time required for the clock input signal to fall from V_{IH} min to V_{IL} max or to rise from V_{IL} max to V_{IH} min. In the vicinity of normal room temperature, the devices function with input clock transition time as slow as 2 microseconds for remote data acquisition applications where the sensor and the A/D converter are placed several feet away from the controlling microprocessor.

ADVANCE INFORMATION

principles of operation

The TLC1540 and TLC1541 are both complete data acquisition systems on single chips. Each includes such functions as sample-and-hold, 10-bit A/D converter, data and control registers, and control logic. For flexibility and access speed, there are four control inputs; Chip Select (\overline{CS}), Address Input, I/O Clock, and System Clock. These control inputs and a TTL-compatible three-state output are intended for serial communications with a microprocessor or microcomputer. The TLC1540 and TLC1541 can complete conversions in a maximum of 21 microseconds, while complete input-conversion-output cycles can be repeated at a maximum of 31 microseconds.

The System and I/O Clocks are normally used independently and do not require any special speed or phase relationships between them. This independence simplifies the hardware and software control tasks for the device. Once a clock signal within the specification range is applied to the System Clock input, the control hardware and software need only be concerned with addressing the desired analog channel, reading the previous conversion result, and starting the conversion by using the I/O Clock. The System Clock will drive the "conversion crunching" circuitry so that the control hardware and software need not be concerned with this task.

When \overline{CS} is high, the Data Output pin is in a three-state condition and the Address Input and I/O Clock pins are disabled. This feature allows each of these pins, with the exception of the \overline{CS} pin, to share a control logic point with their counterpart pins on additional A/D devices when additional TLC1540/1541 devices are used. In this way, the above feature serves to minimize the required control logic pins when using multiple A/D devices.

The control sequence has been designed to minimize the time and effort required to initiate conversion and obtain the conversion result. A normal control sequence is:

1. \overline{CS} is brought low. To minimize errors caused by noise at the \overline{CS} input, the internal circuitry waits for two rising edges and then a falling edge of the System Clock after a low \overline{CS} transition, before the low transition is recognized. This technique is used to protect the device against noise when the device is used in a noisy environment. The MSB of the previous conversion result will automatically appear on the Data Out pin.
2. A new positive-logic multiplexer address is shifted in on the first four rising edges of the I/O Clock. The MSB of the address is shifted in first. The negative edges of these four I/O Clock pulses shift out the second, third, fourth, and fifth most significant bits of the previous conversion result. The on-chip sample-and-hold begins sampling the newly addressed analog input after the fourth falling edge. The sampling operation basically involves the charging of internal capacitors to the level of the analog input voltage.
3. Five clock cycles are then applied to the I/O pin and the sixth, seventh, eighth, ninth, and tenth conversion bits are shifted out on the negative edges of these clock cycles.
4. The final tenth clock cycle is applied to the I/O Clock pin. The falling edge of this clock cycle completes the analog sampling process and initiates the hold function. Conversion is then performed during the next 44 System Clock cycles. After this final I/O Clock cycle, \overline{CS} must go high or the I/O Clock must remain low for at least 44 System Clock cycles to allow for the conversion function.

\overline{CS} can be kept low during periods of multiple conversion. When keeping \overline{CS} low during periods of multiple conversion, special care must be exercised to prevent noise glitches on the I/O Clock line. If glitches occur on the I/O Clock line, the I/O sequence between the microprocessor/controller and the device will lose synchronization. Also, if \overline{CS} is taken high, it must remain high until the end of the conversion. Otherwise, a valid falling edge of \overline{CS} will cause a reset condition, which will abort the conversion in progress.

A new conversion may be started and the ongoing conversion simultaneously aborted by performing steps 1 through 4 before the 44 System Clock cycles occur. Such action will yield the conversion result of the previous conversion and not the ongoing conversion.

principles of operation (continued)

It is possible to connect the System and I/O Clock pins together in special situations in which controlling circuitry points must be minimized. In this case, the following special points must be considered in addition to the requirements of the normal control sequence previously described.

1. When \overline{CS} is recognized by the device to be at a low level, the common clock signal is used as an I/O Clock. When \overline{CS} is recognized by the device to be at a high level, the common clock signal is used to drive the "conversion crunching" circuitry.
2. The device will recognize a \overline{CS} low transition only when the \overline{CS} input changes and subsequently the System Clock pin receives two positive edges and then a negative edge. For this reason, after a \overline{CS} negative edge, the first two clock cycles will not shift in the address because a low \overline{CS} must be recognized before the I/O Clock can shift in an analog channel address. Also, upon shifting in the address, \overline{CS} must be raised after the eighth I/O Clock that has been recognized by the device, so that a \overline{CS} low level will be recognized upon the lowering of the tenth I/O Clock signal that is recognized by the device. Otherwise, additional common clock cycles will be recognized as I/O Clock pulses and will shift in an erroneous address.

For certain applications, such as strobing applications, it is necessary to start conversion at a specific point in time. This device will accommodate these applications. Although the on-chip sample-and-hold begins sampling upon the negative edge of the fourth I/O Clock cycle, the hold function is not initiated until the negative edge of the tenth I/O Clock cycle. Thus, the control circuitry can leave the I/O Clock signal in its high state during the tenth I/O Clock cycle until the moment at which the analog signal must be converted. The TLC1540/TLC1541 will continue sampling the analog input until the tenth falling edge of the I/O Clock. The control circuitry or software will then immediately lower the I/O Clock signal and hold the analog signal at the desired point in time and start conversion.

Detailed information on interfacing to most popular microprocessors is readily available from the factory.

TLC4016M, TLC4016I SILICON-GATE CMOS QUADRUPLE BILATERAL ANALOG SWITCH

D2922, JANUARY 1986

- High Degree of Linearity
- High On-Off Output Voltage Ratio
- Low Crosstalk Between Switches
- Low On-State Impedance of 50 Ohms Typ at $V_{CC} = 9\text{ V}$
- Individual Switch Controls
- Extremely Low Input Current

(TOP VIEW)

description

The TLC4016 is a silicon-gate CMOS quadruple analog switch integrated circuit designed to handle both analog and digital signals. Each switch permits signals with amplitudes up to 12 volts peak to be transmitted in either direction.

Each switch section has its own enable input control. A high-level voltage applied to this control terminal turns on the associated switch section.

Applications include signal gating, chopping, modulation or demodulation (modem), and signal multiplexing for analog-to-digital and digital-to-analog conversion systems.

The TLC4016M is characterized for operation from -55°C to 125°C , and the TLC4016I is characterized from -40°C to 85°C .

Caution. This device has limited built-in gate protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage.

description

The TLC7135 converter is manufactured with Texas Instruments highly efficient ADVANCED LinCMOS™ technology. This 4 1/2-digit dual-slope-integrating analog-to-digital converter is designed to provide interfaces to both a microprocessor and a visual display. The digit-drive outputs D1 through D4 and multiplexed binary-coded-decimal outputs, B1 through B4, provide an interface for LED or LCD decoder/drivers as well as microprocessors.

The TLC7135 offers 50-ppm (one part in 20,000) resolution with a maximum linearity error of one count. The zero error is less than 10 μV and zero drift is less than 0.5 μV/°C. Source-impedance errors are minimized by low input current (less than 10 pA). Rollover error is limited to ±1 count.

The TLC7135 BUSY, STROBE, RUN/HOLD, OVER-RANGE, and UNDER-RANGE control signals support microprocessor-based measurement systems. The control signals also can support remote data acquisition systems with data transfer via universal asynchronous receiver transmitters (UARTs).

The TLC7135 is characterized for operation from 0°C to 70°C.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

A measurement cycle for the TLC7135 consists of the following four phases.

1. **Auto-Zero Phase.** The internal IN+ and IN- inputs are disconnected from the pins and internally connected to ANLG COMMON. The reference capacitor is charged to the reference voltage. The system is configured in a closed loop and the auto-zero capacitor is charged to compensate for offset voltages in the buffer amplifier, integrator, and comparator. The auto-zero accuracy is limited only by the system noise, and the overall offset, as referred to the input, is less than 10 μ V.
2. **Signal Integrate Phase.** The auto-zero loop is opened and the internal IN+ and IN- inputs are connected to the external pins. The differential voltage between these inputs is integrated for a fixed period of time. If the input signal has no return with respect to the converter power supply, IN- can be tied to ANLG COMMON to establish the correct common-mode voltage. Upon completion of this phase, the polarity of the input signal is recorded.
3. **De-integrate Phase.** The reference is used to perform the de-integrate task. The internal IN- is internally connected to ANLG COMMON and IN+ is connected across the previously charged reference capacitor. The recorded polarity of the input signal is used to ensure that the capacitor will be connected with the correct polarity so that the integrator output polarity will return to zero. The time, which is required for the output to return to zero, is proportional to the amplitude of the input signal. The return time is displayed as a digital reading and is determined by the equation $10,000 \times (V_{ID}/V_{ref})$. The maximum or full-scale conversion occurs when V_{ID} is two times V_{ref} .
4. **Zero Integrator Phase.** The internal IN- is connected to ANLG COMMON. The system is configured in a closed loop to cause the integrator output to return to zero. Typically this phase requires 100 to 200 clock pulses. However, after an over-range conversion, 6200 pulses are required.

description of analog circuits

input signal range

The common mode range of the input amplifier extends from 1 V above the negative supply to 1 V below the positive supply. Within this range, the common mode rejection ratio (CMRR) is typically 86 dB. Both differential and common mode voltages cause the integrator output to swing. Therefore, care must be exercised to assure the integrator output does not saturate.

analog common

Analog common (ANLG COMMON) is connected to the internal IN- during the auto-zero, de-integrate, and zero integrator phases. If IN- is connected to a voltage which is different than analog common during the signal integrate phase, the resulting common mode voltage will be rejected by the amplifier. However, in most applications, IN LO will be set at a known fixed voltage (power supply common for instance). In this application, analog common should be tied to the same point, thus removing the common mode voltage from the converter. Removing the common mode voltage in this manner will slightly increase conversion accuracy.

reference

The reference voltage is positive with respect to analog common. The accuracy of the conversion result is dependent upon the quality of the reference. Therefore, to obtain a high accuracy conversion, a high quality reference should be used.

description of digital circuits

2

Data Acquisition Circuits

RUN/HOLD input

When the **RUN/HOLD** input is high or open, the device will continuously perform measurement cycles every 40,002 clock pulses. If this input is taken low, the IC will continue to perform the ongoing measurement cycle and then hold the conversion reading for as long as the pin is held low. If the pin is held low after completion of a measurement cycle, a short positive pulse (greater than 300 ns) will initiate a new measurement cycle. If this positive pulse occurs before the completion of a measurement cycle, it will not be recognized. The first **STROBE** pulse, which occurs 101 counts after the end of a measurement cycle, is an indication of the completion of a measurement cycle. Thus, the positive pulse could be used to trigger the start of a new measurement after the first **STROBE** pulse.

STROBE input

Negative going pulses from this input are used to transfer the BCD conversion data to external latches, UARTS, or microprocessors. At the end of the measurement cycle, the digit-drive (D5) input goes high and remains high for 201 counts. The most significant digit (MSD) BCD bits are placed on the BCD pins. After the first 101 counts, halfway through the duration of output D1-D5 going high, the **STROBE** pin goes low for 1/2 clock pulse width. The placement of the **STROBE** pulse at the midpoint of the D5 high pulse allows the information to be latched into an external device on either a low-level or an edge. Such placement of the **STROBE** pulse also ensures that the BCD bits for the second MSD will not yet be competing for the BCD lines and latching of the correct bits is assured. The above process is repeated for the second MSD and the D4 output. Similarly, the process is repeated through the least significant digit (LSD). Subsequently, inputs D5 through D1 and the BCD lines will continue scanning without the inclusion of **STROBE** pulses. This subsequent continuous scanning causes the conversion results to be continuously displayed. Such subsequent scanning does not occur when an over-range condition occurs.

BUSY output

The **BUSY** output goes high at the beginning of the signal integrate phase and remains high until the first clock pulse after zero-crossing or at the end of the measurement cycle if an over-range condition occurs. It is possible to use the **BUSY** pin to serially transmit the conversion result. Serial transmission can be accomplished by ANDing the **BUSY** and **CLOCK** signals and transmitting the ANDed output. The transmitted output consists of 10,001 clock pulses, which occur during the signal integrate phase, and the number of clock pulses, which occur during the de-integrate phase. The conversion result can be obtained by subtracting 10,001 from the total number of clock pulses.

OVER-RANGE output

When an over-range condition occurs, this pin goes high after the **BUSY** signal goes low at the end of the measurement cycle. As previously noted, the **BUSY** signal remains high until the end of the measurement cycle when an over-range condition occurs. The **OVER-RANGE** output goes high at end of **BUSY** and goes low at the beginning of the de-integrate phase in the next measurement cycle.

UNDER-RANGE output

At the end of the **BUSY** signal, this pin goes high if the conversion result is less than or equal to 9% (count of 1800) of the full-scale range. The **UNDER-RANGE** output is brought low at the beginning of the signal integrate phase of the next measurement cycle.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

POLARITY output

The POLARITY output is high for a positive input signal and is updated at the beginning of each de-integrate phase. The polarity output is valid for all inputs including ± 0 and over-range signals.

digit-drive (D5, D4, D2 and D1) outputs

Each digit-drive output (D1 through D5) sequentially goes high for 200 clock pulses. This sequential process is continuous unless an over-range occurs. When an over-range occurs, all of the digit drive outputs are blanked from the end of the strobe sequence until the beginning of the de-integrate phase (when the sequential digit drive activation begins again). The blanking activity, during an over-range condition, may be used to cause the display to flash and indicate the over-range condition.

BCD outputs

The BCD bits (B8, B4, B2 and B1) for a given digit are sequentially activated on these outputs. Simultaneously, the appropriate Digit-drive line for the given digit is activated.

system aspects

integrating resistor

The value of the integrating resistor (R_{INT}) is determined by the full scale input voltage and the output current of the integrating amplifier. The integrating amplifier can supply $20 \mu A$ of current with negligible non-linearity. The equation for determining the value of this resistor is as follows:

$$R_{INT} = \frac{\text{FULL-SCALE VOLTAGE}}{I_{INT}}$$

Integrating amplifier current, I_{INT} , from 5 to $40 \mu A$ will yield good results. However, the nominal and recommended current is $20 \mu A$.

integrating capacitor

The product of the integrating resistor and capacitor should be selected to give the maximum voltage swing without causing the integrating amplifier output to saturate and get too close to the power supply voltages. If the amplifier output is within 0.3 V of either supply, saturation will occur. With $\pm 5\text{-V}$ supplies and ANLG COMMON connected to ground, the designer should design for a $\pm 3.5\text{-V}$ to $\pm 4\text{-V}$ integrating amplifier swing. A nominal capacitor value is $0.47 \mu F$. The equation for determining the value of the integrating capacitor (C_{INT}) is as follows:

$$C_{INT} = \frac{10,000 \times \text{CLOCK PERIOD} \times I_{INT}}{\text{INTEGRATOR OUTPUT VOLTAGE SWING}}$$

where: I_{INT} is nominally $20 \mu A$.

Capacitors with large tolerances and high dielectric absorption can induce conversion inaccuracies. A capacitor, which is too small could cause the integrating amplifier to saturate. High dielectric absorption causes the effective capacitor value to be different during the signal integrate and de-integrate phases. Polypropylene capacitors have very low dielectric absorption. Polystyrene and Polycarbonate capacitors have higher dielectric absorption, but also work well.

PRINCIPLES OF OPERATION

2

Data Acquisition Circuits

auto-zero and reference capacitor

Large capacitors will tend to reduce noise in the system. Dielectric absorption is unimportant except during power-up or overload recovery. Typical values are 1 μ F.

reference voltage

For high-accuracy absolute measurements, a high quality reference should be used.

rollover resistor and diode

The TLC7135 has a small rollover error, however it can be corrected. The correction is to connect the cathode of any silicon diode to the INT OUT pin and the anode to a resistor. The other end of the resistor is connected to ANLG COMMON or ground. For the recommended operating conditions the resistor value is 100 k Ω . This value may be changed to correct any rollover error which has not been corrected. In many non-critical applications, the resistor and diode are not needed.

maximum clock frequency

For most dual-slope A/D converters, the maximum conversion rate is limited by the frequency response of the comparator. In this circuit, the comparator follows the integrator ramp with a 3 μ s delay. Therefore, with a 160 kHz clock frequency (6 μ s period), half of the first reference integrate clock period is lost in delay. Hence, the meter reading will change from 0 to 1 with a 50 μ V input, 1 to 2 with a 150 μ V input, 2 to 3 with a 250 μ V input, etc. This transition at midpoint is desirable; however, if the clock frequency is increased appreciably above 160 kHz, the instrument will flash "1" on noise peaks even when the input is shorted. The above transition points assume a 2-V input range is equivalent to 20,000 clock cycles.

If the input signal is always of one polarity, comparator delay need not be a limitation. Clock rates of 1 MHz are possible since non-linearity and noise do not increase substantially with frequency. For a fixed clock frequency, the extra count or counts caused by comparator delay will be a constant and can be subtracted out digitally.

For signals with both polarities, the clock frequency can be extended above 160 kHz without error by using a low value resistor in series with the integrating capacitor. This resistor causes the integrator to jump slightly towards the zero-crossing level at the beginning of the de-integrate phase and thus, compensates for the comparator delay. This series resistor should be 10 to 50 ohms. This approach allows clock frequencies up to 480 kHz.

minimum clock frequency

The minimum clock frequency limitations result from capacitor leakage from the auto-zero and reference capacitors. Measurement cycles as high as 10 seconds are not influenced by leakage error.

rejection of 50 Hz or 60 Hz pickup

To maximize the rejection of 50 Hz or 60 Hz pickup, the clock frequency should be chosen so that an integral multiple of 50 Hz or 60 Hz periods occur during the signal integrate phase. To achieve rejection of these signals, some clock frequencies which could be used are as follows:

50 Hz: 250, 166.66, 125, 100 kHz, etc.

60 Hz: 300, 200, 150, 120, 100, 40, 33.33 kHz, etc.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

zero-crossing flip-flop

This flip-flop interrogates the comparator's zero-crossing status. The interrogation is performed after the previous clock cycle and the positive half of the ongoing clock cycle have occurred so that any comparator transients which result from the clock pulses do not affect the detection of a zero-crossing. This procedure delays the zero-crossing detection by one clock cycle. To eliminate the inaccuracy, which is caused by this delay, the counter is disabled for one clock cycle at the beginning of the de-integrate phase. Therefore, when the zero-crossing is detected one clock cycle later than the zero-crossing actually occurs, the correct number of counts is displayed.

noise

The peak-to-peak noise around zero is approximately 15 μV (peak-to-peak value not exceeded 95% of the time). Near full scale, this value increases to approximately 30 μV . Much of the noise originates in the auto-zero loop, and is proportional to the ratio of the input signal to the reference.

analog and digital grounds

For high-accuracy applications, ground loops must be avoided. Return currents from digital circuits must not be sent to the analog ground line.

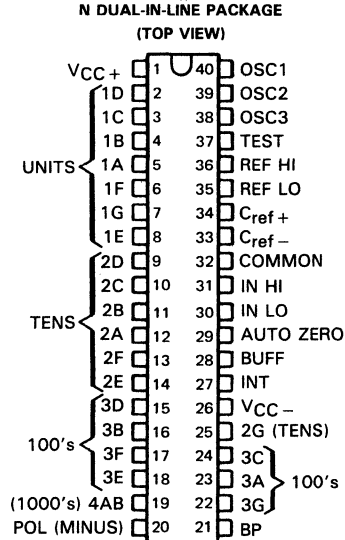

power supplies

The TLC7135 is designed to work with $\pm 5\text{-V}$ power supplies. However, 5-V operation is possible if the input signal does not vary more than $\pm 1.5\text{ V}$ from mid-supply.

Caution. These devices have limited built-in gate protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

description

The TLC7136C is a high-performance, very low-power 3 1/2-digit analog-to-digital converter (ADC). The TLC7136C contains seven-segment decoders, display drivers, a clock, and a reference. This device is designed to interface with liquid crystal displays and incorporates a backplane drive. The device can easily be powered with a 9-volt battery because the supply current is less than 100 microamperes.

The TLC7136C provides high accuracy and versatility and such features as auto-zeroing to less than 10 microvolts, zero drift of less than 1 μ V/°C, maximum input bias current of 10 picoamperes, and rollover error of less than 1 count.

The differential input and on-chip reference are particularly useful when measuring load cells, strain gauges, and other bridge-type transducers. Single-supply operation provides economy in that a high-performance panel meter can be built with only seven passive components and a display. The TLC7136C is an improved version of the Intersil ICL7126 in that overrange hangover and hysteresis effects are eliminated.

The TLC7136C is characterized for operation from 0°C to 70°C.

PRINCIPLES OF OPERATION

2

Data Acquisition Circuits

A measurement cycle, for the TLC7136C, consists of four phases. The four phases are as follows:

1. **Auto-Zero Phase.** The internal IN HI and IN LO inputs are disconnected from the pins and are internally connected to analog COMMON. The reference capacitor is charged to the reference voltage. The system is configured in a closed loop and the auto-zero capacitor is charged to compensate for offset voltages in the buffer amplifier, integrator, and comparator. The auto-zero accuracy is limited only by the system noise, and the overall offset, as referred to the input, is less than 10 microvolts.
2. **Signal Integrate Phase.** The auto-zero loop is opened and the internal IN HI and IN LO inputs are connected to the external pins. The differential voltage between these inputs is integrated for a fixed period of time. If the input signal has no return with respect to the converter power supply, IN LO can be tied to analog COMMON to establish the correct common-mode voltage. Upon completion of this phase, the polarity of the input signal is recorded.
3. **Deintegrate (reference-integrate) Phase.** The reference is used to perform the deintegrating task, which is performed in the following manner. The IN LO is internally connected to analog COMMON and IN HI is connected across the previously charged reference capacitor. The recorded polarity of the input signal is used to ensure that the capacitor will be connected with the correct polarity so that the integrator output will return to zero. The time that is required for the output to return to zero is proportional to the amplitude of the input signal. The return time is displayed as a digital reading and is determined by the equation $1000 V_{ID}/V_{ref}$.
4. **Zero Integrator Phase.** The internal IN LO is connected to analog COMMON. The system is configured in a closed loop to cause the integrator output to return to zero. Typically this phase requires 11 to 140 clock pulses. However, after an overrange conversion, 740 pulses are required.

description of analog circuits

input signal range

The common-mode range of the input amplifier extends from 1 volt above the negative supply to 0.5 volt below the positive supply. Within this range, the common mode rejection ratio (CMRR) is typically 86 dB.

The common-mode signal also causes the integrator output to swing and there is a possibility that the integrator output could saturate. This saturation, which causes an incorrect conversion, is most likely with the combination of a large positive common mode voltage and a large negative differential voltage. The negative differential voltage causes the integrator output to go positive when most of the integrator's positive output swing capability has been used up by the large positive common mode voltage. In such situations, the integrator swing can be reduced to less than the recommended 2-volt swing with a minimal reduction in accuracy. The linear range of the integrator output is within 0.3 volts of either supply.

differential reference

The reference voltage must lie within the device power supply range. The major source of common-mode error is caused by the loss or gain of charge from the reference capacitor due to stray capacitances. With large common-mode voltages, the reference capacitor will gain charge or voltage while deintegrating a positive signal and, conversely, lose charge or voltage while deintegrating a negative signal. This gain or loss of reference capacitor voltage will cause a rollover error. The selection of a reference capacitor that is large in comparison to the stray capacitance will reduce the rollover error to less than 0.5 counts (see Component Value Selection).

analog common

For battery operation or when the inputs are floating with respect to the TLC7136C power supply, the analog COMMON pin is used to set the common mode voltage. The COMMON pin is preset by internal circuits to a voltage that is approximately 3 volts less than the TLC7136C positive supply. This preset voltage will give a 6-volt end-of-battery life.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

2

Data Acquisition Circuits

When the power supply voltage is greater than 7 volts, the TLC7136C zener will be in a regulating mode and the preset voltage at the COMMON pin will have reference-like qualities. The preset voltage will then have a low 0.001%-per-volt voltage coefficient, a low output impedance of approximately 35 ohms, and a temperature coefficient of less than 80 ppm/°C. Therefore, the preset voltage could be used for an on-chip reference, however, there are some limitations. For 2°C to 8°C temperature changes, a scale factor of one count or more can result. Also, if the power supply voltage drops below 7 volts, the voltage coefficient will be poor since the zener will no longer be in a regulating mode.

Analog COMMON is connected to the internal IN LO during the auto-zero, deintegrate, and zero integrator phases. If IN LO is connected to a voltage that is different from analog common during the signal-integrate phase, the resulting common-mode voltage will be rejected by the amplifier. However, in certain applications, IN LO is set at a fixed known voltage, for example the power supply common voltage. For these applications, the COMMON pin should be tied to IN LO to eliminate the common-mode rejection error. The same consideration applies to the reference voltage. Referring the reference voltage to analog COMMON eliminates another common-mode error source. Referring the reference voltage to an analog common is accomplished by connecting COMMON to either REF LO or REF HI.

test

The TEST pin performs two functions. First, it is connected to the internally generated digital supply (negative side) through a 500-ohm resistor. This connection allows the TEST pin to be used as the negative supply for external segment drivers, such as decimal points or any LCD segment that requires up to 1-milliampere load current. Second, the pin performs a test function. When the TEST pin is pulled up to V_{CC+} , all segments will turn on and the display will read - 1888. In this test mode, a constant DC voltage is applied to the segments, rather than a square wave, and the segments may be damaged if the test is prolonged.

description of digital circuits

An internal digital ground is generated with a 6-volt zener diode and a large P-channel source follower. This generated supply can handle the large capacitive currents that result when the backplane (BP) voltage is switched. Dividing the clock frequency by 800 gives the BP frequency. For 3 readings per second, the BP signal is a 5-volt, 60-Hz squarewave. The segments that are driven at the same frequency and amplitude are in phase with BP when off, and out of phase with BP when on. Except in the test mode, a negligible amount of DC voltage is placed across the segments. For negative-polarity inputs, the polarity indication will become active. Also, if the placement of IN LO and IN HI is switched, the polarity indication can be switched accordingly.

system timing

The TLC7136C clock circuit is shown in Figure 3. The three possible clock setups are pin 40 connected to an external oscillator, a crystal between pins 39 and 40, or an RC oscillator with connections to pins 38, 39, and 40.

The frequency of the clock oscillator is first divided by four and then the resulting clock signal is used to clock the decade counters. The divide-by-four clock signal is then further divided to form the four convert-cycle phases, which are as follows:

1. 1,000 counts for signal integration.
2. 0 to 2,000 counts for reference deintegration.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

2

Data Acquisition Circuits

3. 11 to 140 counts for zero integration (with an overranged conversion of greater than 2,060 counts, the zero integrator phase will require 740 counts, and auto-zero will require 260 counts).
4. 910 to 2900 counts for auto-zero (for signals less than full-scale, auto-zero gets the unused portion of reference deintegration and zero integration).

The total measurement cycle requires 4,000 counts or 16,000 clock pulses. A 48-kilohertz oscillator would be required for three readings per second.

NOTE: This figure shows all three external control circuits connected; however, only one external circuit (crystal, RC network or external oscillator) is connected for proper operation.

FIGURE 3. CLOCK CIRCUITS

component value selection

integrating resistor

The buffer amplifier and integrator class A output stages require approximately 6 microamperes of quiescent current and can source -1 microampere of current without inducing any significant nonlinearity. The integrating resistor should be sufficiently large that the buffer amplifier and integrator will remain in this linear region. However, the resistor must also be small enough that PC board leakage remains insignificant. Values of 180 kilohms and 1.8 megohms are recommended for the respective 200-millivolt and 2-volt full-scale voltages.

integrating capacitor

The integrating capacitor should be chosen to give the maximum voltage swing, yet not allow the combined tolerances of the integrating resistor and capacitor to cause the integrator to saturate. The linear range of the integrator extends to within 0.3 volt of V_{CC-} or V_{CC+} . A +2-volt full-scale integrator swing works fine when analog common is used as the reference. Capacitor values of 0.047 microfarad and 0.15 microfarad are recommended for 3 (48-kilohertz oscillator) and 1 (16-kilohertz oscillator) readings per second respectively. As the oscillator frequency is increased, the capacitor value must be decreased to maintain the same output swing. Polypropylene capacitors are recommended because of their reasonable cost and low dielectric absorption, which produces low roll-over errors.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

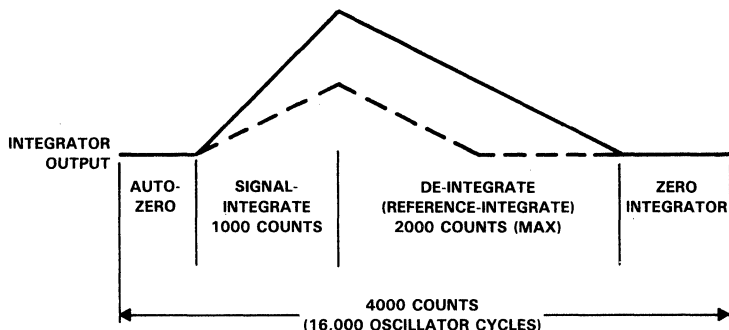

FIGURE 4. TIMING DIAGRAM

auto-zero capacitor

The size of this capacitor has an effect upon the noise of the system. For 200-millivolt full-scale applications, in which noise must be kept to a minimum, a 0.47-microfarad capacitor is recommended. The zero-integrator phase allows the use of a large auto-zero capacitor without the accompanying hysteresis or overrange hangover problems that can occur with the ICL7126 or ICL7106.

reference capacitor

A 0.1-microfarad capacitor is fine for most applications. However, with large common-mode signals, if the REF LO pin is not connected to analog COMMON and the full-scale voltage is 200 millivolts, a larger capacitor is required to prevent rollover error. A 1-microfarad capacitor will hold this rollover error to 0.5 counts.

oscillator components

A 50-pF capacitor is recommended for all frequency ranges. The resistor can be selected from the equation:

$$f = 0.45/RC$$

where: R = 180 kilohms for 48-kilohertz oscillator (3 readings per second) and 560 kilohms for 16-kilohertz oscillator (1 reading per second).

reference voltage

An input voltage of $2 V_{ref}$ is required to obtain a full-scale reading of 2,000 counts. Therefore, for a full-scale of 200 millivolts and 2 volts, V_{ref} should be 100 millivolts and 1 volt respectively. In many situations, the designer might like to have a full-scale voltage other than 200 millivolts or 2 volts. In situations where the designer desires a full-scale voltage of X volts, the designer can select a V_{ref} of X/2 volts. The value of the integrating resistor can be determined by the following equation:

$$\frac{X \text{ volts (desired full-scale)}}{200 \text{ mV}} = \frac{\text{Value of Integrating Resistor for X volts full-scale}}{180 \text{ k}\Omega \text{ (integrating resistor for 200 mV full-scale)}}$$

If X volts is greater than 200 millivolts, it is better to work with an X/2 volts reference, since dividing the X volts down to 200 millivolts will cause the input signal to be more susceptible to noise.

Sometimes a designer will want a digital reading of zero when V_I does not equal zero. This desire can be met by connecting V_I between IN HI and COMMON and the zero-reading V_I between COMMON and IN LO.

description

The TLC7524 is an Advanced LinCMOS™ 8-bit digital-to-analog converter (DAC) designed for easy interface to most popular microprocessors.

The TLC7524 is an 8-bit multiplying DAC with input latches and with a load cycle similar to the "write" cycle of a random access memory. Segmenting the high-order bits minimizes glitches during changes in the most-significant bits, which produce the highest glitch impulse. The TLC7524 provides accuracy to ½ LSB without the need for thin-film resistors or laser trimming, while dissipating less than 5 milliwatts typically.

Featuring operation from a 5-V to 15-V single supply, the TLC7524 interfaces easily to most microprocessor buses or output ports. Excellent multiplying (2 or 4 quadrant) makes the TLC7524 an ideal choice for many microprocessor-controlled gain-setting and signal-control applications.

The TLC7524I is characterized for operation from -25°C to 85°C, and the TLC7524C is characterized for operation from 0°C to 70°C.

principles of operation

The TLC7524 is an 8-bit multiplying D/A converter consisting of an inverted R-2R ladder, analog switches, and data input latches. Binary weighted currents are switched between the OUT1 and OUT2 bus lines, thus maintaining a constant current in each ladder leg independent of the switch state. The high-order bits are decoded and these decoded bits, through a modification in the R-2R ladder, control three equally weighted current sources. Most applications only require the addition of an external operational amplifier and a voltage reference.

The equivalent circuit for all digital inputs low is seen in Figure 1. With all digital inputs low, the entire reference current, I_{ref} , is switched to OUT2. The current source $I/256$ represents the constant current flowing through the termination resistor of the R-2R ladder, while the current source I_{lk} represents leakage currents to the substrate. The capacitances appearing at OUT1 and OUT2 are dependent upon the digital input code. With all digital inputs high, the off-state switch capacitance (30 pF maximum) appears at OUT2 and the on-state switch capacitance (120 pF maximum) appears at OUT1. With all digital inputs low, the situation is reversed as shown in Figure 1. Analysis of the circuit for all digital inputs high is similar to Figure 1; however, in this case, I_{ref} would be switched to OUT1.

Interfacing the TLC7524 D/A converter to a microprocessor is accomplished via the data bus and the \overline{CS} and \overline{WR} control signals. When \overline{CS} and \overline{WR} are both low, the TLC7524 analog output responds to the data activity on the DB0-DB7 data bus inputs. In this mode, the input latches are transparent and input data directly affects the analog output. When either the \overline{CS} signal or \overline{WR} signal goes high, the data on the DB0-DB7 inputs are latched until the \overline{CS} and \overline{WR} signals go low again. When \overline{CS} is high, the data inputs are disabled regardless of the state of the \overline{WR} signal.

The TLC7524 is capable of performing 2-quadrant or full 4-quadrant multiplication. Circuit configurations for 2-quadrant or 4-quadrant multiplication are shown in Figures 2 and 3. Input coding for unipolar and bipolar operation are summarized in Tables 1 and 2, respectively.

description

The TLC7528 is a dual 8-bit digital-to-analog converter designed with separate on-chip data latches and featuring excellent DAC-to-DAC matching. Data is transferred to either of the two DAC data latches via a common 8-bit input port. Control input $\overline{\text{DACA/DACB}}$ determines which DAC is to be loaded. The "load" cycle of the TLC7528 is similar to the "write" cycle of a random-access memory, allowing easy interface to most popular microprocessor busses and output ports. Segmenting the high-order bits minimizes glitches during changes in the most significant bits, where glitch impulse is typically the strongest.

The TLC7528 operates from a 5-volt to 15-volt power supply and dissipates less than 15 mW (typical). Excellent 2- or 4-quadrant multiplying makes the TLC7528 a sound choice for many microprocessor-controlled gain-setting and signal-control applications.

The TLC7528I is characterized for operation from -25 to 85°C . The TLC7528C is characterized for operation from 0°C to 70°C .

 7. Both DAC latches loaded with 11111111; V_{refB} = 20 V peak-to-peak, 100-kHz sine wave; V_{refA} = 0; T_A = 25°C.

principles of operation

The TLC7528 contains two identical 8-bit multiplying D/A converters, DACA and DACB. Each DAC consists of an inverted R-2R ladder, analog switches, and input data latches. Binary-weighted currents are switched between DAC output and AGND, thus maintaining a constant current in each ladder leg independent of the switch state. Most applications require only the addition of an external operational amplifier and voltage reference. A simplified D/A circuit for DACA with all digital inputs low is shown in Figure 1.

Figure 2 shows the DACA equivalent circuit. A similar equivalent circuit can be drawn for DACB. Both DACs share the analog ground pin 1 (AGND). With all digital inputs high, the entire reference current flows to OUTA. A small leakage current (I_{lkg}) flows across internal junctions, and as with most semiconductor devices, doubles every 10°C. C_O is due to the parallel combination of the NMOS switches and has a value that depends on the number of switches connected to the output. The range of C_O is 50 pF to 120 pF maximum. The equivalent output resistance r_O varies with the input code from 0.8R to 3R where R is the nominal value of the ladder resistor in the R-2R network.

Interfacing the TLC7528 to a microprocessor is accomplished via the data bus, \overline{CS} , \overline{WR} , and $\overline{DACA}/\overline{DACB}$ control signals. When \overline{CS} and \overline{WR} are both low, the TLC7528 analog output, specified by the $\overline{DACA}/\overline{DACB}$ control line, responds to the activity on the DB0-DB7 data bus inputs. In this mode, the input latches are transparent and input data directly affects the analog output. When either the \overline{CS} signal or \overline{WR} signal goes high, the data on the DB0-DB7 inputs is latched until the \overline{CS} and \overline{WR} signals go low again. When \overline{CS} is high, the data inputs are disabled regardless of the state of the \overline{WR} signal.

The digital inputs of the TLC7528 provide TTL compatibility when operated from a supply voltage of 5 V. The TLC7528 may be operated with any supply voltage in the range from 5 V to 15 V, however, input logic levels are not TTL compatible above 5 V.

TYPICAL APPLICATION DATA

The TLC7528 is capable of performing 2-quadrant or full 4-quadrant multiplication. Circuit configurations for 2-quadrant and 4-quadrant multiplication are shown in Figures 3 and 4. Input coding for unipolar and bipolar operation are summarized in Tables 1 and 2, respectively.

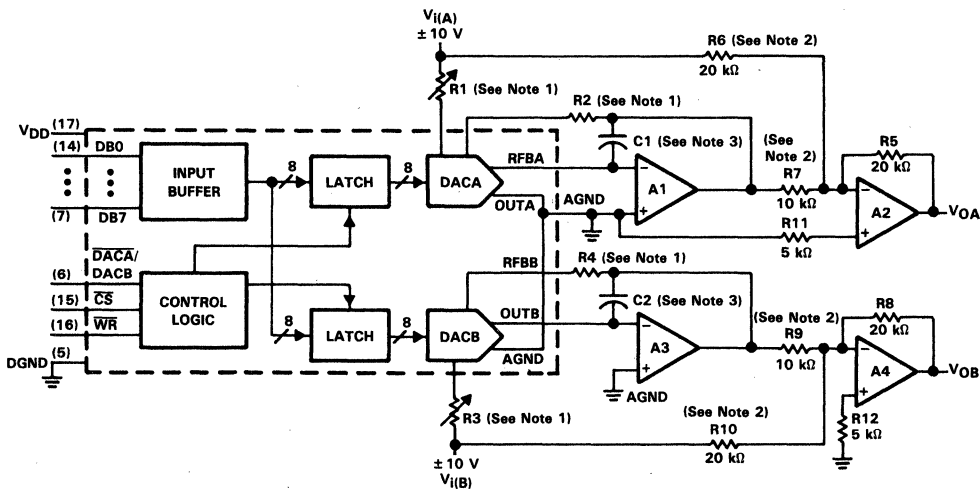

- NOTES: 1. R1, R2, R3, and R4 are used only if gain adjustment is required. See table for recommended values. Make gain adjustment with digital input of 255.
2. C1 and C2 phase compensation capacitors (10 pF to 15 pF) are required when using high-speed amplifiers to prevent ringing or oscillation.

programmable state-variable filter

This programmable state-variable or universal filter configuration provides low-pass, high-pass, and band-pass outputs, and is suitable for applications in which microprocessor control of filter parameters is required.

As shown in Figure 10, DACA1 and DACB1 control the gain and Q of the filter while DACA2 and DACB2 control the cutoff frequency. Both halves of the DACA2 and DACB2 must track accurately in order for the cutoff-frequency equation to be true. With the TLC7528, this is easily achieved.

$$f_c = \frac{1}{2\pi R_1 C_1}$$

The programmable range for the cutoff or center frequency is 0 to 15 kHz with a Q ranging from 0.3 to 4.5. This defines the limits of the component values.

CIRCUIT EQUATIONS:
 $C_1 = C_2, R_1 = R_2, R_4 = R_5$

$$Q = \frac{R_3}{R_4} \cdot \frac{R_F}{R_{fb}(DACB1)}$$

$$A_o = - \frac{R_F}{R_S}$$

- NOTES: A. Op-amps A1, A2, A3, and A4 are TL287.
 B. C3 compensates for the op-amp gain-bandwidth limitations.
 C. DAC equivalent resistance equals $\frac{256 \times (\text{DAC ladder resistance})}{\text{DAC digital code}}$

description

The TLC7533 is an ADVANCED LinCMOS™ 10-bit digital-to-analog converter featuring two- and four-quadrant multiplication.

The TLC7533 is pin and functionally equivalent to the AD7520 and AD7533. Texas Instruments advanced thin-film-on-monolithic-CMOS fabrication process provides 10-bit linearity without laser trimming.

The TLC7533 features TTL or CMOS compatibility with low input leakage currents from 5-V to 15-V power supplies. Output scaling is provided by an internal feedback resistor and an external operational amplifier. Both positive and negative reference voltages can be utilized.

The TLC7533I is characterized for operation from -25°C to 85°C. The TLC7533C is characterized for operation from 0°C to 70°C.

NOTES: 4. Practical Full Scale Range (FSR) = $V_{ref} - 1$ LSB.

5. Gain error is measured using the internal feedback resistor. Full-Scale (FS) = $-V_{ref}$ (1023/1024). Maximum gain change from $T_A = 25^\circ\text{C}$ to minimum or maximum temperature is 0.1% FSR.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION

The TLC7533 is a 10-bit multiplying D/A converter consisting of an inverted R-2R ladder and analog switches. Binary-weighted currents are switched between the OUT1 and OUT2 bus lines by NMOS current switches. The on-state resistances of these switches are binarily scaled so that the voltage drop across every switch is the same. The OUT1 and OUT2 bus lines should be maintained at the same potential so that the current in each ladder leg remains constant and is independent of the switch state. Most applications require only the addition of an external operational amplifier and a voltage reference.

The equivalent circuit for all digital inputs low is shown in Figure 1. With all of the digital inputs low, the entire reference current, I_{ref} , is switched to OUT2 as shown in Figure 2. The current source $I_{ref}/1024$ represents the constant current flowing through the termination resistor of the R-2R ladder; while the current source I_{lkg} represents leakage currents to the substrate. The output capacitances, $C_{O(1)}$ and $C_{O(2)}$, are due to the capacitance of the NMOS current switches and vary with the switch state. With all digital inputs low, all of the current switches and the entire resistor ladder are switched to the OUT2 bus line. The capacitance appearing at OUT2 is a maximum of 100 pF; at OUT1 there is a maximum of 35 pF. With all digital inputs high, all of the current switches are switched to OUT1, and 100 pF maximum appears at OUT1. A maximum of 35 pF appears at OUT2 as shown in Figure 3.

FIGURE 2. DAC EQUIVALENT CIRCUIT — ALL DIGITAL INPUTS LOW

FIGURE 3. DAC EQUIVALENT CIRCUIT — ALL DIGITAL INPUTS HIGH

TYPICAL APPLICATION DATA

The TLC7533 is capable of performing 2-quadrant or full 4-quadrant multiplication. Circuit configurations for 2-quadrant or 4-quadrant multiplication are shown in Figures 4 and 5. Input coding for unipolar and bipolar operation are summarized in Tables 1 and 2, respectively.

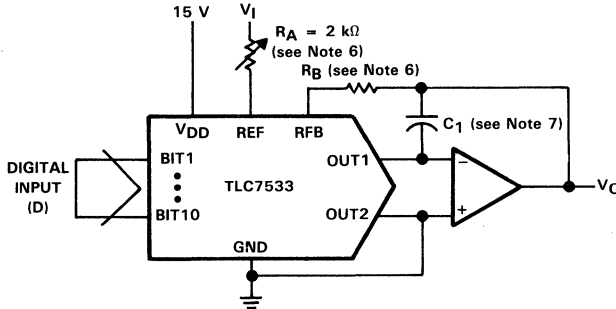

FIGURE 4. UNIPOLAR OPERATION (2-QUADRANT MULTIPLICATION)

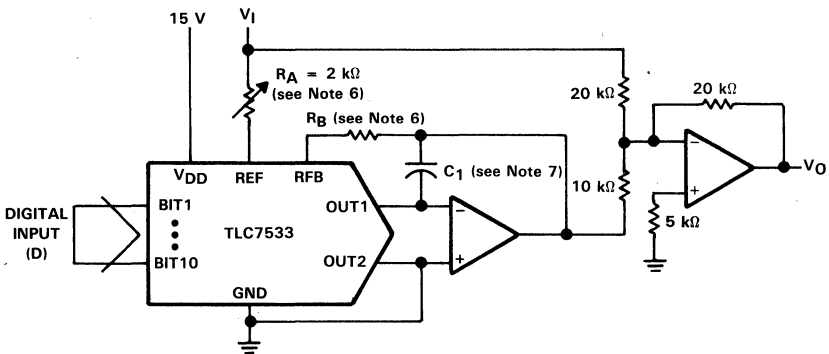

FIGURE 5. BIPOLAR OPERATION (4-QUADRANT OPERATION)

NOTES: 6. R_A and R_B are used only if gain adjustment is required.
 7. C_1 (10-33 pF) may be required for phase compensation when using high-speed op-amps.

0000000001	$-V_I (511/512)$
0000000000	$-V_I (512/512) = -V_I$

TYPICAL APPLICATION DATA

The TLC7533 may be used in voltage output operation as shown in Figure 6. In this configuration, the input voltage is applied to the OUT1 terminal and the output voltage is taken from the REF terminal. The output voltage varies with the digital input code according to the equation shown. The output should be buffered to prevent loading errors due to the high output resistance of this circuit (typically 10 kilohms). The input voltage should not exceed 1.5 volts to ensure nonlinearity errors less than 1 LSB.

FIGURE 6. VOLTAGE OUTPUT OPERATION

By connecting the DAC in the feedback of an op-amp as shown in Figure 7, the circuit behaves as a programmable gain amplifier with the transfer function:

$$V_O = -V_I \left(\frac{1024}{D} \right)$$

where D = Digital Input Code (expressed as a decimal number)

description

The TLC32040 is a complete analog-to-digital and digital-to-analog input/output system on a single monolithic CMOS chip. This device integrates a bandpass switched-capacitor antialiasing input filter, a 14-bit resolution A/D converter, four microprocessor-compatible serial port modes, a 14-bit resolution D/A converter, and a low-pass switched-capacitor output-reconstruction filter. The device offers numerous combinations of Master Clock input frequencies and conversion/sampling rates, which can be changed via digital processor control.

Typical applications for this IC include modems (7.2-, 8-, 9.6-, 14.4-, and 19.2-kHz sampling rate), analog interface for digital signal processors, speech recognition/storage systems, industrial process control, biomedical instrumentation, acoustical signal processing, spectral analysis, data acquisition, and instrumentation recorders. Four serial modes, which allow direct interface to the TMS32011, TMS32020, and TMS32025 digital signal processors, are provided. Also, when the transmit and receive sections of the Analog Interface Circuit (AIC) are operating synchronously, it will interface to two SN54299 or SN74299 serial-to-parallel shift registers. These serial-to-parallel shift registers can then interface in parallel to the TMS32010, other digital signal processors, or external FIFO circuitry. Output data pulses are emitted to inform the processor that data transmission is complete, or to allow the DSP to differentiate between two transmitted bytes. A flexible control scheme is provided so that the functions of the IC can be selected and adjusted coincidentally with signal processing via software control.

The antialiasing input filter comprises seventh-order and fourth-order CC-type (Chebyshev/elliptic transitional) low-pass and high-pass filters, respectively, and a fourth-order equalizer. The input filter is implemented in switched-capacitor technology and is preceded by a continuous time filter to eliminate any possibility of aliasing caused by sampled data filtering. When no filtering is desired, the entire composite filter can be switched out of the signal path. A selectable, auxiliary, differential analog input is provided for applications where more than one analog input is required.

PRODUCT PREVIEW

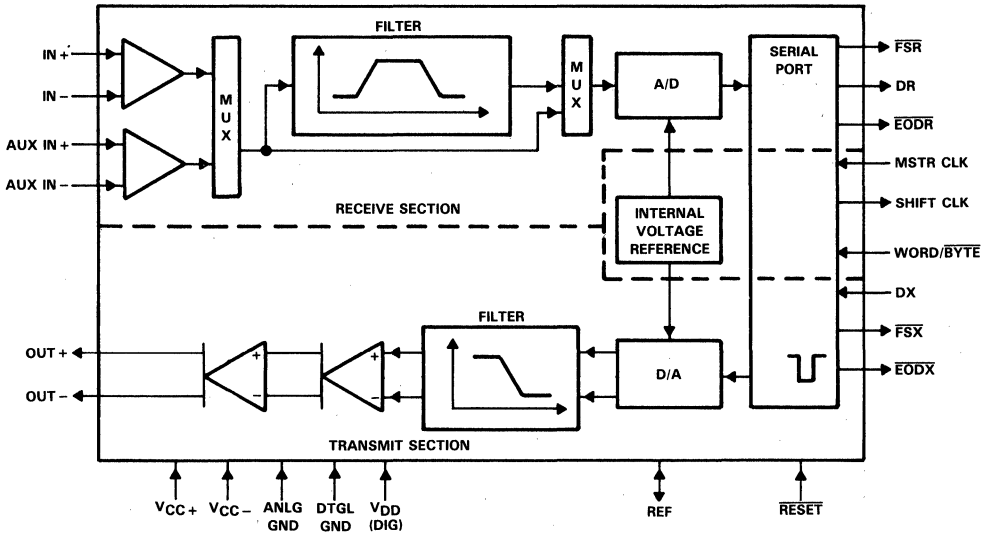

description (continued)

The A/D and D/A converters each have 14 bits of resolution with 10 bits of integral linearity guaranteed over any 10-bit range. The A/D and D/A architectures guarantee no missing codes and monotonic operation. An internal voltage reference is provided to ease the design task and to provide complete control over the performance of the IC. The internal voltage is brought out to a pin and is available to the designer. Separate analog and digital voltage supplies and grounds are provided to minimize noise and ensure a wide dynamic range. Also, the analog circuit path contains only differential circuitry to keep noise to an absolute minimum. The only exception is the DAC sample-and-hold, which utilizes pseudo-differential circuitry.

The output-reconstruction filter is a seventh-order CC-type (Chebyshev/elliptic transitional low-pass filter with a fourth-order equalizer) and is implemented in switched-capacitor technology. This filter is followed by a continuous-time filter to eliminate images of the digitally encoded signal.

The TLC32040M is characterized for operation over the full military temperature range of -55°C to 125°C , and the TLC32040I is characterized for operation from -40°C to 85°C .

functional block diagram

PRINCIPLES OF OPERATION

analog input

Two sets of analog inputs, IN +, IN -, and AUX IN +, AUX IN -, are provided. Each input set can be operated in either differential or single-ended modes, since sufficient common-mode range and rejection are provided. Normally, the IN + and IN - inputs are used; however, the auxiliary inputs, AUX IN + and AUX IN -, can be used if a second input is required. The gain for the IN +, IN -, and auxiliary AUX IN + and AUX IN - inputs can be programmed to either 1, 2, or 4 (see the Gain Control Table). Either input circuit can be selected via software control. It is important to note that a wide dynamic range is assured by the differential internal analog architecture and by the separate analog and digital voltage supplies and grounds.

A/D bandpass filter, A/D bandpass filter clocking, and A/D conversion rate timing

The A/D bandpass filter can be selected or bypassed via software control. The frequency response of this filter is presented in the following pages. This response results when the switched-capacitor filter clock frequency is 288 kHz. Several possible options can be used to attain a 288-kHz switched-capacitor filter clock. When the filter clock frequency is not 288 kHz, the filter transfer function is frequency-scaled by the ratio of the actual clock frequency to 288 kHz. The low-frequency roll-off of the high-pass section is 300 kHz. However, the high-pass section low-frequency roll-off can be changed to 200 kHz with a metal mask option.

The Internal Timing Configuration and AIC DX Data Word Format sections of this data sheet indicate the many options for attaining a 288-kHz bandpass switched-capacitor filter clock. These sections indicate that the RX Counter A can be programmed to give a 288-kHz bandpass-switched capacitor filter clock for several Master Clock input frequencies.

The A/D conversion rate is then attained by frequency-dividing the 288-kHz bandpass switched-capacitor filter clock with the RX Counter B. Thus, unwanted aliasing is prevented because the A/D conversion rate is an integral submultiple of the bandpass switched-capacitor filter sampling rate, and the two rates are synchronously locked.

A/D converter performance specifications

Fundamental performance specifications for the A/D converter circuitry are presented in the A/D converter operating characteristics section of this data sheet. The realization of the A/D converter circuitry with switched-capacitor techniques provides an inherent sample-and-hold.

analog output

The analog output circuitry is an analog output power amplifier. Both noninverting and inverting amplifier outputs are brought out of the IC. This amplifier can drive transformer hybrids or low-impedance loads directly in either a differential or single-ended configuration.

D/A low-pass filter, D/A low-pass filter clocking, and D/A conversion rate timing

The frequency response of this filter is presented in the following pages. This response results when the low-pass switched-capacitor filter clock frequency is 288 kHz. Like the A/D filter, the transfer function of this filter is frequency-scaled when the clock frequency is not 288 kHz. A continuous-time filter is provided on the output of the D/A low-pass filter to greatly attenuate any switched-capacitor clock feedthrough.

The D/A conversion rate is then attained by frequency-dividing the 288-kHz switched-capacitor filter clock with TX Counter B. Thus, unwanted aliasing is prevented because the D/A conversion rate is an integral submultiple of the switched-capacitor low-pass filter sampling rate, and the two rates are synchronously locked.

PRINCIPLES OF OPERATION (continued)

2

Data Acquisition Circuits

asynchronous versus synchronous operation

If the transmit section of the AIC (low-pass filter and DAC) and receive section (bandpass filter and ADC) are operated asynchronously, the low-pass and band-pass filter clocks are independently generated from the Master Clock signal. Also, the D/A and A/D conversion rates are independently determined. If the transmit and receive sections are operated synchronously, the low-pass filter clock drives both low-pass and band-pass filters. In synchronous operation, the A/D conversion timing is derived from, and is equal to, the D/A conversion rate timing. (See description of the WORD/BYTE pin in the Pin Functional Description Section.)

D/A converter performance specifications

Fundamental performance specifications for the D/A converter circuitry are presented in the D/A converter operating characteristics section of the data sheet. The D/A converter has a sample-and-hold that is realized with a switched-capacitor ladder.

system frequency response correction

Sin x/x correction circuitry is performed in digital signal processor software. The system frequency response can be corrected via DSP software to ± 0.1 dB accuracy to a band-edge of 3000 Hz for all sampling rates. This correction is accomplished with a first-order digital correction filter, which requires only seven TMS320 instruction cycles. With a 200-ns instruction cycle, seven instructions represent an overhead factor of only 1.1% and 1.3% for sampling rates of 8 and 9.6 kHz, respectively (see the sin x/x Correction Section for more details).

serial port

The serial port has four possible modes that are described in detail in the pin description section. These modes are briefly described below.

1. The transmit and receive sections of the AIC are operated asynchronously, and the AIC serial port interfaces directly with the TMS32011.
2. The transmit and receive sections of the AIC are operated asynchronously, and the AIC serial port interfaces directly with the TMS32020 and the TMS32025.
3. The transmit and receive sections of the AIC are operated synchronously, and the AIC serial port interfaces directly with the TMS32011.
4. The transmit and receive sections of the AIC are operated synchronously, and the AIC serial port interfaces directly with the TMS32020, TMS32025, or two SN54299 or SN74299 serial-to-parallel shift registers, which can then interface in parallel to the TMS32010, to any other digital signal processor, or to external FIFO circuitry.

testing

An addendum accompanying this data sheet fully describes the test capabilities of the IC, provided by the design.

internal voltage reference

The internal reference eliminates the need for an external voltage reference, and thus provides overall circuit cost reduction. Additionally, the internal reference makes the performance of the IC less susceptible to noise. Thus, the internal reference eases the design task and provides complete control over the performance of the IC. The internal reference is brought out to a pin and is available to the designer. To keep the amount of noise on the reference signal to a minimum, an external capacitor may be connected between REF and ANLG GND.

PRODUCT PREVIEW

PRINCIPLES OF OPERATION (continued)

reset

A reset function is provided to initiate serial communications between the AIC and DSP and to allow fast, cost-effective testing during manufacturing. The reset function will initialize all AIC registers, including the control register. The reset pin has an internal pull-up resistor. After a negative-going pulse on the RESET pin, the AIC will be initialized. This initialization allows normal serial port communications activity to occur between AIC and DSP (see AIC DX Data Word Format section).

loopback

This feature allows the user to test the circuit remotely. In loopback, the OUT + and OUT – pins are internally connected to the IN + and IN – pins. Thus, the DAC bits (d15 to d2), which are transmitted to the DX pin, can be compared with the ADC bits (d15 to d2), which are received from the DR pin. An ideal comparison would be that the bits on the DR pin equal the bits on the DX pin. However, in practice there will be some difference in these bits due to the ADC and DAC output offsets.

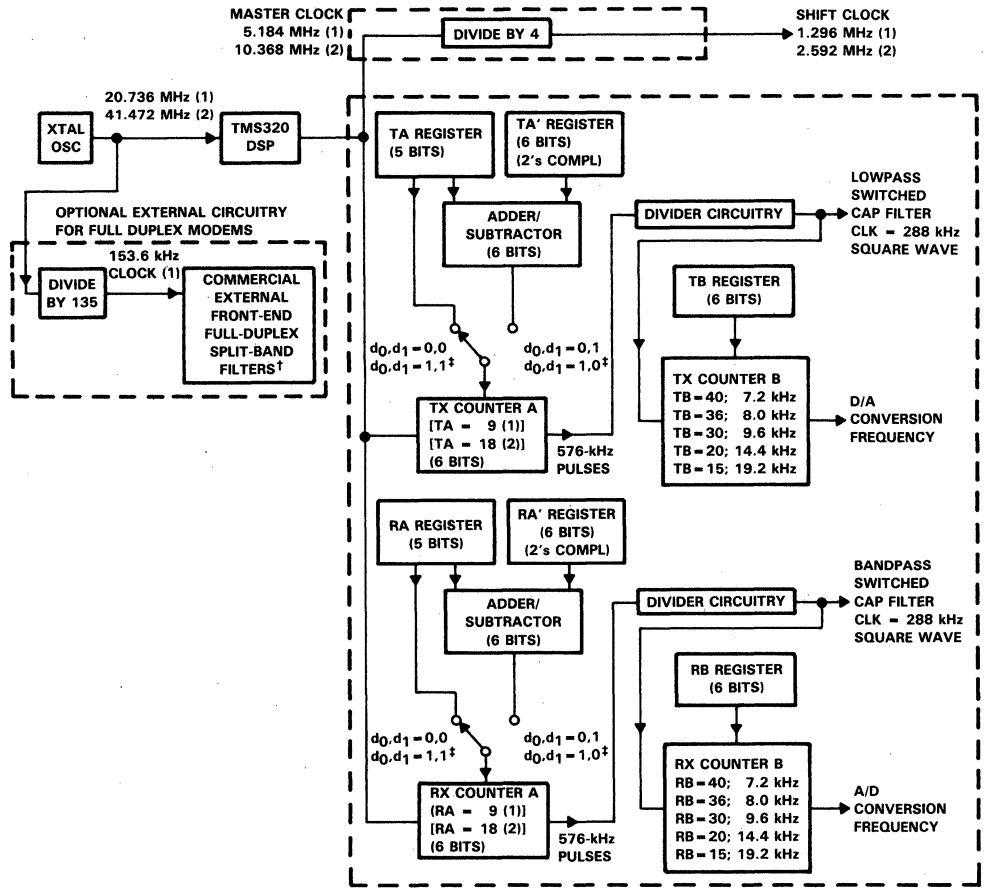

The loopback feature is implemented with digital signal processor control by transmitting the appropriate serial port bit to the control register (see AIC Data Word Format section).

PIN		I/O	DESCRIPTION
NAME	NO.		
ANLG GND	17,18		Analog ground return for all internal analog circuits. Not internally connected to DGTL GND.
AUX IN +	24	I	Noninverting auxiliary analog input stage. This input can be switched into the bandpass filter and A/D converter path via software control. If the appropriate bit in the Control register is a 1, the auxiliary inputs will replace the IN + and IN – inputs. If the bit is a 0, the IN + and IN – inputs will be used (see the AIC DX Data Word Format section).
AUX IN –	23	I	Inverting auxiliary analog input (see the above AUX IN + pin description).
DGTL GND	9		Digital ground for all internal logic circuits. Not internally connected to ANLG GND.
DR	5	O	This pin is used to transmit the ADC output bits from the AIC to the TMS320 serial port. This transmission of bits from the AIC to the TMS320 serial port is synchronized with the SHIFT CLK signal.
DX	12	I	This pin is used to receive the DAC input bits and timing and control information from the TMS320. This serial transmission from the TMS320 serial port to the AIC is synchronized with the SHIFT CLK signal.
EODR	2	O	(See the WORD/BYTE pin description and the Serial Port Timing Diagram.) During the word-mode timing, this signal is a low-going pulse that occurs immediately after the 16 bits of A/D information have been transmitted from the AIC to the TMS320 serial port. This signal can be used to interrupt a microprocessor upon completion of serial communications. Also, this signal can be used to strobe and enable external serial-to-parallel shift registers, latches, or external FIFO RAM, and to facilitate parallel data bus communications between the AIC and the serial-to-parallel shift registers. During the byte-mode timing, this signal goes low after the first byte has been transmitted from the AIC to the TMS320 serial port and is kept low until the second byte has been transmitted. The TMS32011 can use this low-going signal to differentiate between the two bytes as to which is first and which is second.

PIN		I/O	DESCRIPTION
NAME	NO.		
EODX	11	O	(See the WORD/BYTE pin description and the Serial Port Timing Diagram.) During the word-mode timing, this signal is a low-going pulse that occurs immediately after the 16 bits of D/A converter and control or register information have been transmitted from the TMS320 serial port to the AIC. This signal can be used to interrupt a microprocessor upon the completion of serial communications. Also, this signal can be used to strobe and enable external serial-to-parallel shift registers, latches, or an external FIFO RAM, and to facilitate parallel, data-bus communications between the AIC and the serial-to-parallel shift registers. During the byte-mode timing, this signal goes low after the first byte has been transmitted from the TMS320 serial port to the AIC and is kept low until the second byte has been transmitted. The TMS32011 can use this low-going signal to differentiate between the two bytes as to which is first and which is second.
FSR	4	O	In the serial transmission modes, which are described in the WORD/BYTE pin description, the FSR pin is held low during bit transmission. When the FSR pin goes low, the TMS320 serial port will begin receiving bits from the AIC via the DR pin of the AIC. The most significant DR bit will be present on the DR pin before FSR goes low. (See Serial Port Timing and Internal Timing Configuration Diagrams.)
FSX	14	O	When this pin goes low, the TMS320 serial port will begin transmitting bits to the AIC via the DX pin AIC. In all serial transmission modes, which are described in the WORD/BYTE pin description, the FSX pin is held low during bit transmission (see Serial Port Timing and Internal Timing Configuration Diagrams).
IN +	26	I	Noninverting input to analog input amplifier stage
IN -	25	I	Inverting input to analog input amplifier stage
MSTR CLK	6	I	The Master Clock signal is used to derive all the key logic signals of the AIC, such as the Shift Clock, the switched-capacitor filter clocks, and the A/D and D/A timing signals. The Internal Timing Configuration diagram shows how these key signals are derived. The frequencies of these key signals are synchronous submultiples of the Master Clock frequency to eliminate unwanted aliasing when the sampled analog signals are transferred between the switched-capacitor filters and the A/D and D/A converters (see the Internal Timing Configuration).
OUT +	22	O	Noninverting output of analog output power amplifier. Can drive transformer hybrids or high-impedance loads directly in either a differential or a single-ended configuration.
OUT -	21	O	Inverting output of analog output power amplifier; functionally identical with and complementary to OUT +.
REF	8		The internal voltage reference is brought out to this pin.
RESET	2	I	A reset function is provided to initialize the TA, TA', TB, RA, RA', RB, and control registers. This reset function initiates serial communications between the AIC and DSP. The reset function will initialize all AIC registers including the control register. After a negative-going pulse on the RESET pin, the AIC registers will be initialized to provide an 8-kHz data conversion rate for a 5.184-MHz master clock input signal. The conversion rate adjust registers, TA' and RA', will be reset to 1. The CONTROL register bits will be reset as follows (see AIC DX Data Word Format section). d7 = 1, d6 = 1, d5 = 1, d4 = 0, d3 = 0, d2 = 1 This initialization allows normal serial-port communication to occur between AIC and DSP. This pin has an internal pull-up resistor and is set to a high logic level unless it is pulled to ground.
SHIFT CLK	10	O	The Shift Clock signal is obtained by dividing the Master Clock signal frequency by four. This signal is used to clock the serial data transfers of the AIC, described in the WORD/BYTE pin description below (see the Serial Port Timing and Internal Timing Configuration diagram).
VDD	7		Digital supply voltage, 5 V \pm 5%
VCC+	20		Positive analog supply voltage, 5 V \pm 5%
VCC-	19		Negative analog supply voltage -5 V \pm 5%

PIN NAME NO.	I/O	DESCRIPTION
WORD/BYTE 13	I	<p>This pin, in conjunction with a bit in the CONTROL register, is used to establish one of four serial modes. These four serial modes are described below. This pin has an internal pull-up resistor and is set to a logic high unless it is pulled to ground.</p> <p><i>AIC transmit and receive sections are operated asynchronously.</i></p> <p>The following description applies when the AIC is configured to have asynchronous transmit and receive sections. If the appropriate data bit in the Control register is a 0 (see the AIC DX Data Word Format), the transmit and receive sections will be asynchronous.</p> <ul style="list-style-type: none"> L Serial port will directly interface with the serial port of the TMS32011 and communicates in two 8-bit bytes. The operation sequence is as follows (see Serial Port Timing diagrams). <ol style="list-style-type: none"> 1. The \overline{FSX} or \overline{FSR} pin is brought low. 2. One 8-bit byte is transmitted or one 8-bit byte is received. 3. The \overline{EODX} or \overline{EODR} pin is brought low. 4. The \overline{FSX} or \overline{FSR} pin emits a positive frame-sync pulse that is four Shift Clock cycles wide. 5. One 8-bit byte is transmitted or one 8-bit byte is received. 6. The \overline{EODX} or \overline{EODR} pin is brought high. 7. The \overline{FSX} or \overline{FSR} pin is brought high. H Serial port will directly interface with the serial port of the TMS32020 and communicates in one 16-bit word. The operation sequence is as follows (see Serial Port Timing diagrams): <ol style="list-style-type: none"> 1. The \overline{FSX} or \overline{FSR} pin is brought low. 2. One 16-bit word is transmitted or one 16-bit word is received. 3. The \overline{FSX} or \overline{FSR} pin is brought high. 4. The \overline{EODX} or \overline{EODR} pin emits a low-going pulse. <p><i>AIC transmit and receive sections are operated synchronously.</i></p> <p>If the appropriate data bit in the Control register is a 1, the transmit and receive sections will be configured to be synchronous. In this case, the bandpass switched-capacitor filter and the A/D conversion timing will be derived from the TX Counter A, TX Counter B, and TA, TA', and TB registers, rather than the RX Counter A, RX Counter B, and RA, RA', and RB registers. In this case, the AIC \overline{FSX} and \overline{FSR} timing will be identical, as will the \overline{EODX} and \overline{EODR} timing. The synchronous operation sequences are as follows (see Serial Port Timing diagrams).</p> <ul style="list-style-type: none"> L Serial port will directly interface with the serial port of the TMS32011 and communicates in two 8-bit bytes. The operation sequence is as follows (see Serial Port Timing diagrams): <ol style="list-style-type: none"> 1. The \overline{FSX} and \overline{FSR} pins are brought low. 2. One 8-bit byte is transmitted and one 8-bit byte is received. 3. The \overline{EODX} and \overline{EODR} pins are brought low. 4. The \overline{FSX} and \overline{FSR} pins emit positive frame-sync pulses that are four Shift Clock cycles wide. 5. One 8-bit byte is transmitted and one 8-bit byte is received. 6. The \overline{EODX} and \overline{EODR} pins are brought high. 7. The \overline{FSX} and \overline{FSR} pins are brought high. H Serial port will directly interface with the serial port of the TMS32020 and communicates in one 16-bit word. The operation sequence is as follows (see Serial Port Timing diagrams): <ol style="list-style-type: none"> 1. The \overline{FSX} and \overline{FSR} pins are brought low. 2. One 16-bit word is transmitted and one 16-bit word is received. 3. The \overline{FSX} and \overline{FSR} pins are brought high. 4. The \overline{EODX} or \overline{EODR} pins emit low-going pulses. <p>Since the transmit and receive sections of the AIC are now synchronous, the AIC serial port, with additional NOR and AND gates, will interface to two SN54299 or SN74299 serial-to-parallel shift registers. Interfacing the AIC to the SN54299 or SN74299 shift register allows the AIC to interface to an external FIFO RAM and facilitates parallel, data bus communications between the AIC and the digital signal processor. The operation sequence is the same as the above sequence (see Serial Port Timing diagrams).</p>

INTERNAL TIMING CONFIGURATION

NOTE: Frequency 1, 20.736 MHz, is used to show how 153.6 kHz (for a commercially available modem split-band filter clock), popular speech and modem sampling signal frequencies, and an internal 288-kHz switched-capacitor filter clock can be derived synchronously and as submultiples of the crystal oscillator frequency. Since these derived frequencies are synchronous submultiples of the crystal frequency, aliasing does not occur as the sampled analog signal passes between the analog converter and switched-capacitor filter stages. Frequency 2, 41.472 MHz, is used to show that the AIC can work with high-frequency signals, which are used by high-speed digital signal processors.

† Split-band filtering can alternatively be performed after the analog input function via software in the TMS320.
‡ These control bits are described in the AIC DX Data Word Format section.

explanation of internal timing configuration

All of the internal timing of the AIC is derived from the high-frequency clock signal that drives the Master Clock input pin. The Shift Clock signal, which strobes the serial port data between the AIC and DSP, is derived by dividing the Master Clock input signal frequency by four.

TX Counter A and TX Counter B, which are driven by the Master Clock signal, determine the D/A conversion period timing. Similarly, RX Counter A and RX Counter B determine the A/D conversion period timing. In order for the switched-capacitor low-pass and band-pass filters to meet their transfer function specifications, the frequency of the clock inputs of the switched-capacitor filter must be 288 kHz. If the frequencies of the clock inputs are not 288 kHz, the filter transfer function frequencies are scaled by the ratios of the clock frequencies to 288 kHz. Thus, to obtain the specified filter responses, the combination of Master Clock frequency and TX Counter A and RX Counter A values must yield 288-kHz switched-capacitor clock signals. These 288-kHz clock signals can then be divided by the TX Counter B and RX Counter B to establish the D/A and A/D conversion period timings.

TX Counter A and TX Counter B are reloaded every D/A conversion period, while RX Counter A and RX Counter B are reloaded every A/D conversion period. The TX Counter B and RX Counter B are loaded with the values in the TB and RB Registers respectively. Via software control, the TX Counter A can be loaded with either the TA Register, the TA Register less the TA' Register, or the TA Register plus the TA' Register. By selecting the TA Register less the TA' Register option, the upcoming conversion period timing will occur earlier by an amount of time that equals TA' times the signal period of the Master Clock. By selecting the TA Register plus the TA' Register option, the upcoming conversion period timing will occur later by an amount of time that equals TA' times the signal period of the Master Clock. Thus, the D/A conversion timing can be advanced or retarded. An identical ability to alter the A/D conversion timing is provided. In this case, however, the RX Counter A can be programmed via software control with the RA Register, the RA Register less the RA' Register, or the RA Register plus the RA' Register.

The above feature is particularly useful for modem applications. This feature allows controlled changes in the A/D and D/A conversion timing. This feature can be used to enhance signal-to-noise performance, to perform frequency-tracking functions, and to generate nonstandard modem frequencies.

If the transmit and receive sections are configured to be synchronous (see WORD/BYTE pin description), then both the low-pass and bandpass switched-capacitor filter clocks are derived from TX Counter A. Also, both the D/A and A/D conversion timing are derived from the TX Counter A and TX Counter B. When the transmit and receive sections are configured to be asynchronous, the RX Counter A, RX Counter B, RA Register, RA' Register, and RB Registers are not used.

AIC DR or DX word bit pattern

A/D or D/A MSB

AIC DX data word format section

d15	d14	d13	d12	d11	d10	d9	d8	d7	d6	d5	d4	d2	d1	d0	COMMENTS	
primary DX serial communication protocol																
← d15 (MSB) through d2 go to the D/A converter register													→	0	0	The TX and RX Counter A's are loaded with the TA and RA register values. The TX and RX Counter B's are loaded with TB and RB register values.
← d15 (MSB) through d2 go to the D/A converter register													→	0	1	The TX and RX Counter A's are loaded with the TA + TA' and RA + RA' register values. The TX and RX Counter B's are loaded with the TB and RB register values. NOTE: d1 = 0, d0 = 1 will cause the next D/A and A/D conversion periods to be changed by the addition of TA' and RA' Master Clock cycles, in which TA' and RA' can be positive or negative or zero. Please refer to the Conversion Period Adjustment Error Detection Table.
← d15 (MSB) through d2 go to the D/A converter register													→	1	0	The TX and RX Counter A's are loaded with the TA - TA' and RA - RA' register values. The TX and RX Counter B's are loaded with the TB and RB register values. NOTE: d1 = 1, d0 = 0 will cause the next D/A and A/D conversion periods to be changed by the subtraction of TA' and RA' Master Clock cycles, in which TA' and RA' can be positive or negative or zero. Please refer to the Conversion Period Adjustment Error Detection Table.
← d15 (MSB) through d2 go to the D/A converter register													→	1	1	The TX and RX Counter A's are loaded with the TA and RA register values. The TX and RX Counter B's are loaded with the TB and RB register values. After a delay of four Shift Clock cycles, a secondary transmission will immediately follow to program the AIC to operate in the desired configuration.

NOTE: Setting the two least significant bits to 1 in the normal transmission of DAC information (Primary Communications) to the AIC will initiate Secondary Communications upon completion of the Primary Communications.

Upon completion of the Primary Communication, FSX will remain high for four SHIFT CLOCK cycles and will then go low and initiate the Secondary Communication. The timing specifications for the Primary and Secondary Communications are identical. In this manner, the Secondary Communication, if initiated, is interleaved between successive Primary Communications. This interleaving prevents the Secondary Communication from interfering with the Primary Communications and DAC timing, thus preventing the AIC from skipping a DAC output.

secondary DX serial communication protocol

x	x	← to TA register →	x	x	← to RA register →	0	0	d13 and d6 are MSBs							
x	← to TA' register →	x	← to RA' register →	0	1	d14 and d7 are 2's complement sign bits									
x	← to TB register →	x	← to RB register →	1	0	d14 and d7 are MSBs									
x	x	x	x	x	x	x	x	d7	d6	d5	d4	d3	d2	1	1
← CONTROL REGISTER →													d2 = 0/1 deletes/inserts the bandpass filter		
													d3 = 0/1 disables/enables the loopback function		
													d4 = 0/1 disables/enables the AUX IN+ and AUX IN- pins		
													d5 = 0/1 asynchronous/synchronous transmit and receive sections		
													d6 = 0/1 gain control bits (see Gain Control Section)		
													d7 = 0/1 gain control bits (see Gain Control Section)		

reset function

A reset function is provided to initiate serial communications between the AIC and DSP. The reset function will initialize all AIC registers, including the control register. After a negative-going pulse on the RESET pin, the AIC registers will be initialized to provide an 8-kHz A/D and D/A conversion rate for a 5.184 MHz master clock input signal. The AIC, excepting the CONTROL register, will be initialized as follows (see AIC DX Data Word Format section):

REGISTER	INITIALIZED REGISTER VALUE (HEX)
TA	9
TA'	1
TB	24
RA	9
RA'	1
RB	24

The CONTROL register bits will be reset as follows (see AIC DX Data Word Format section):

$d7 = 1, d6 = 1, d5 = 1, d4 = 0, d3 = 0, d2 = 1$

This initialization allows normal serial port communications to occur between AIC and DSP. If the transmit and receive sections are configured to operate synchronously and the user wishes to program different conversion rates, only the TA, TA', and TB register need to be programmed, since both transmit and receive timing are synchronously derived from these registers (see the pin descriptions and AIC DX Word Format sections).

AIC responses to improper conditions

The AIC has provisions for responding to improper conditions. These improper conditions and the response of the AIC to these conditions are presented in Table 1 below:

AIC register constraints

The following constraints are placed on the contents of the AIC registers:

1. TA register must be > 1 .
2. TA' register can be either positive, negative, or zero.
3. RA register must be > 1 .
4. RA' register can be either positive, negative, or zero.
5. (TA register \pm TA' register) must be > 1 .
6. (RA register \pm RA' register) must be > 1 .
7. TB register must be > 1 .

TABLE 1. AIC RESPONSES TO IMPROPER CONDITIONS

IMPROPER CONDITION	AIC RESPONSE
TA register + TA' register = 0 or 1 TA register - TA' register = 0 or 1	Reprogram TX Counter A with TA register value
TA register + TA' register < 0	MOD 64 arithmetic is used to ensure that a positive value is loaded into the TX Counter A, i.e., TA register + TA' register + 40 HEX is loaded into TX Counter A
RA register + RA' register = 0 or 1 RA register - RA' register = 0 or 1	Reprogram RX Counter A with RA register value
RA register + RA' register = 0 or 1	MOD 64 arithmetic is used to ensure that a positive value is loaded into RX Counter A, i.e., RA register + RA' register + 40 HEX is loaded into RX Counter A
TA register = 0 or 1 RA register = 0 or 1	AIC is shut down
TB register = 0 or 1	Reprogram TB register with 24 HEX
RB register = 0 or 1	Reprogram RB register with 24 HEX
AIC and DSP cannot communicate	Hold last DAC output

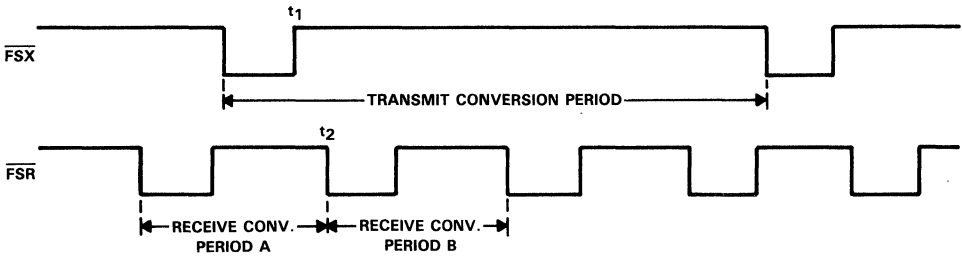

improper operation due to conversion times being too close together

If the difference between two successive D/A conversion frame syncs is less than 1/19.2 kHz, the AIC operates improperly. In this situation, the second D/A conversion frame sync occurs too quickly and there is not enough time for the ongoing conversion to be completed. This situation can occur if the A and B registers are improperly programmed or if the A + A' register or A - A' register result is too small. When incrementally adjusting the conversion period via the A + A' register options, the designer should be very careful not to violate this requirement (see diagram below).

asynchronous operation — more than one receive frame sync occurring between two transmit frame syncs

When incrementally adjusting the conversion period via the $A + A'$ or $A - A'$ register options, a specific protocol is followed. The command to use the incremental conversion period adjust option is sent to the AIC during a FSX frame sync. The ongoing conversion period is then adjusted. However, either Receive Conversion Period A or B may be adjusted. For both transmit and receive conversion periods, the incremental conversion period adjustment is performed near the end of the conversion period. Therefore, if there is sufficient time between t_1 and t_2 , the receive conversion period adjustment will be performed during Receive Conversion Period A. Otherwise, the adjustment will be performed during Receive Conversion Period B. The adjustment command only adjusts one transmit conversion period and one receive conversion period. To adjust another pair of transmit and receive conversion periods, another command must be issued during a subsequent FSX frame (see figure below).

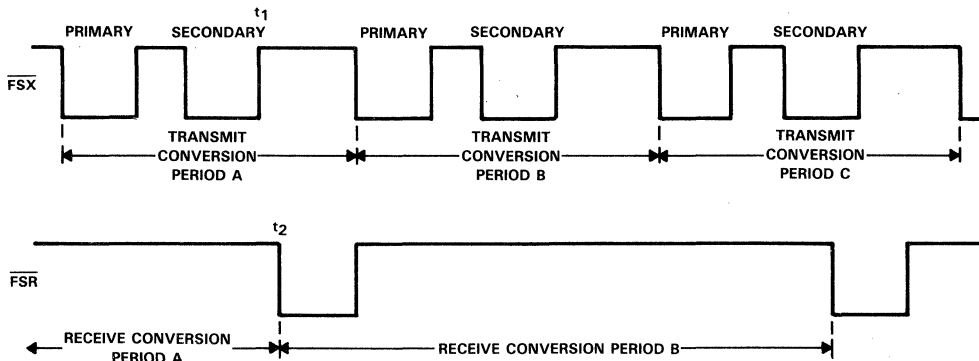

asynchronous operation — more than one transmit frame sync occurring between two receive frame syncs

When incrementally adjusting the conversion period via the $A + A'$ or $A - A'$ register options, a specific protocol is followed. For both transmit and receive conversion periods, the incremental conversion period adjustment is performed near the end of the conversion period. The command to use the incremental conversion period adjust options is sent to the AIC during a FSX frame sync. The ongoing transmit conversion period is then adjusted. However, three possibilities exist for the receive conversion period adjustment in the diagram as shown in the figure below. If the adjustment command is issued during Transmit Conversion Period A, Receive Conversion Period A will be adjusted if there is sufficient time between t_1 and t_2 . Or, if there is not sufficient time between t_1 and t_2 , Receive Conversion Period B will be adjusted. Or, the receive portion of an adjustment command may be ignored if the adjustment command is sent during a receive conversion period, which is already being or will be adjusted due to a prior adjustment command. For example, if adjustment commands are issued during Transmit Conversion Periods A, B, and C, the first two commands may cause Receive Conversion Periods A and B to be adjusted, while the third receive adjustment command is ignored. The third adjustment command is ignored since it was issued during Receive Conversion Period B, which already will be adjusted via the Transmit Conversion Period B adjustment command.

asynchronous operation — more than one set of primary and secondary DX serial communication occurring between two receive frame sync (see AIC DX Data Word Format section)

The TA, TA', TB, and control register information that is transmitted in the secondary communications is always accepted and is applied during the ongoing transmit conversion period. If there is sufficient time between t_1 and t_2 , the TA, RA', and RB register information, which is sent during Transmit Conversion Period A, will be applied to Receive Conversion Period A. Otherwise, this information will be applied during Receive Conversion Period B. If RA, RA', and RB register information has already been received and is being applied during an ongoing conversion period, any subsequent RA, RA', or RB information that is received during this receive conversion period will be disregarded (see diagram below).

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC+} (see Note 1)	-0.3 V to 15 V
Supply voltage, V_{DD}	-0.3 V to 15 V
Output voltage, V_O	-0.3 V to 15 V
Input voltage, V_I	-0.3 V to 15 V
Digital ground voltage	-0.3 V to 15 V
Operating free-air temperature range: TLC32040M	-55°C to 125°C
TLC32040I	-40°C to 85°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds: J package	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: N package	260°C

NOTE 1: Voltage values for maximum ratings are with respect to V_{CC-} .

recommended operating conditions

PARAMETER	MIN	NOM	MAX	UNIT	
Supply voltage, V_{CC+} (see Note 2)	4.75	5	5.25	V	
Supply voltage, V_{CC-} (see Note 2)	-4.75	-5	-5.25	V	
Digital supply voltage, V_{DD} (see Note 2)	4.75	5	5.25	V	
Digital ground voltage with respect to ANLG GND, DGTL GND		0		V	
High-level input voltage, V_{IH}	2		$V_{DD}+0.3$	V	
Low-level input voltage, V_{IL} (see Note 3)	-0.3		0.8	V	
Load resistance at OUT+ and/or OUT-, R_L		300		Ω

A/D or D/A conversion rate			19.2	kHz	
Operating free-air temperature, T_A	TLC32040M		-55	125	$^{\circ}\text{C}$
	TLC32040I		-40	85	

- NOTES:
2. Voltages at analog inputs and outputs, V_{CC+} , and V_{CC-} , are with respect to the ANLG GND terminal. Voltages at digital inputs and outputs and V_{CC+} (DIG) are with respect to the DGTL GND terminal.
 3. The algebraic convention, in which the least positive (most negative) value is designated minimum, is used in this data sheet for logic voltage levels and temperature only.
 4. The bandpass and low-pass switched-capacitor filter responses are only guaranteed when the switched-capacitor clock frequency is 288 kHz. For switched-capacitor filter clocks at frequencies other than 288 kHz, the filter response is shifted by the ratio of switched-capacitor filter clock frequency to 288 kHz.
 5. This range applies when (IN+ - IN-) or (AUX+ - AUX-) equals ± 6 V.

electrical characteristics over recommended operating free-air temperature range, $V_{CC+} = 5\text{ V}$, $V_{CC-} = -5\text{ V}$, $V_{DD} = 5\text{ V}$ (unless otherwise noted)

total device, MSTR CLK frequency = 5.184 MHz, outputs not loaded

FIGURE 1. $\text{IN}+$ AND $\text{IN}-$ GAIN CONTROL CIRCUITRY

FIGURE 2. AUXILIARY INPUT CIRCUITRY

sin x/x correction section

The AIC does not have sin x/x correction circuitry after the digital-to-analog converter. Sin x/x correction can be accomplished easily and efficiently in digital signal processor (DSP) software. Excellent correction accuracy can be achieved to a band edge of 3000 Hz by using a first-order digital correction filter. The results, which are shown below, are typical of the numerical correction accuracy that can be achieved for sample rates of interest. The filter requires only seven instruction cycles per sample on the TMS320 DSPs. With a 200-ns instruction cycle, nine instructions per sample represents an overhead factor of 1.4% and 1.7% for sampling rates of 8000 Hz and 9600 Hz, respectively. This correction will add a slight amount of group delay at the upper edge of the 300–3000-Hz band.

sin x/x roll-off for a zero-order hold function

The sin x/x roll-off for the AIC DAC zero-order hold function at a band-edge frequency of 3000 Hz for the various sampling rates is shown in the table below.

TABLE 2. sin x/x ROLL-OFF

f_s (Hz)	$20 \log \frac{\sin \pi f/f_s}{\pi f/f_s}$ ($f = 3000$ Hz) (dB)
7200	-2.64
8000	-2.11
9600	-1.44
14400	-0.63
19200	-0.35

Note that the actual AIC sin x/x roll-off will be slightly less than the above figures, because the AIC has less than a 100 percent duty cycle hold interval.

correction filter

To compensate for the $\sin x/x$ roll-off of the AIC, the first-order correction filter, which is shown below, is recommended.

The difference equation for this correction filter is:

$$y_{i+1} = p_2(1-p_1) u_{i+1} + p_1 y_i$$

where the constant p_1 determines the pole locations.

The resulting squared magnitude transfer function is:

$$|H(f)|^2 = \frac{p_2^2 (1-p_1)^2}{1 - 2p_1 \cos(2\pi f/f_s) + p_1^2}$$

correction results

Table 3 below shows the optimum p values and the corresponding correction results for 8000 Hz and 9600 Hz sampling rates.

TABLE 3

f (Hz)	ERROR (dB)	ERROR (dB)
	f _s = 8000 Hz p1 = -0.14813 p2 = 0.9888	f _s = 9600 Hz p1 = -0.1307 p2 = 0.9951
300	-0.099	-0.043
600	-0.089	-0.043
900	-0.054	0
1200	-0.002	0
1500	0.041	0
1800	0.079	0.043
2100	0.100	0.043
2400	0.091	0.043
2700	-0.043	0
3000	-0.102	-0.043

TMS320 software requirements

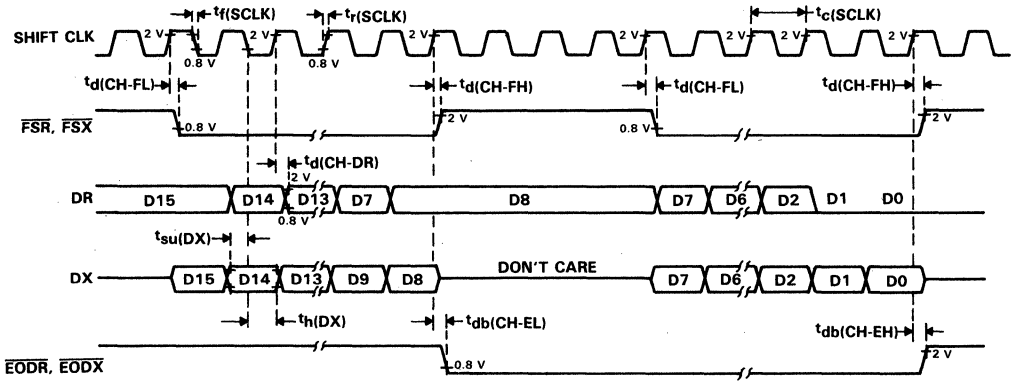

The digital correction filter equation can be written in state variable form as follows:

$$Y = k1Y + k2U$$

where Y is the filter state and U is the next I/O sample. With the assumption that TMS processor page pointer and memory configuration are properly initialized, the equation can be executed in seven instructions or seven cycles with the following program:

```
ZAC
LT K2
MPY U
LTD K1
MPY Y
APAC
SACH (dma)
```

SN55426B, SN55427B AC PLASMA DISPLAY DRIVERS

D2520, MARCH 1979—REVISED OCTOBER 1986

- 90-V Output Swing
- CMOS-Compatible Inputs
- Quad Drivers with Independent Addressing of Each Gate for Serial or Parallel Applications
- High Data Input Impedance . . . 1 M Ω Typ
- 30-mA Clamp Diodes on Output

description

The SN55426B and SN55427B are monolithic integrated-circuit plasma display drivers. The logic of the two drivers is complementary to permit controlled writing or erasing at a specified point on the display. The '426B noninverting pulser is normally near ground potential and is pulsed near V_{CC2}; the '427B inverting pulser is normally near V_{CC2} potential and is pulsed near ground potential. The devices are designed to accept CMOS logic input signals and drive one display line per output.

There are four gates per package with individual data inputs. Additionally, each device has a strobe and a multiplex input controlling all four gates. The devices require two power supplies: the logic section power supply V_{CC1}, and the high-voltage bias supply V_{CC2}. V_{CC2} controls the magnitude of the output swing.

Each output is designed to sustain 20-milliampere switching transients on the output. Each output is also protected by source and sink clamp diodes with 30-milliampere current capability. Each device is designed to be operated at 50 kilohertz but may be operated as high as 85 kilohertz.

The multiplex and strobe inputs (inputs M and S, respectively) act on all four gates simultaneously and aid in plasma panel design.

The SN55426B and SN55427B are characterized for operation over the full military temperature range of -55°C to 125°C.

SN75491, SN75491A, SN75492, SN75492A MOS-TO-LED DRIVERS

D2355, OCTOBER 1972—REVISED SEPTEMBER 1986

QUAD SEGMENT DRIVER AND HEX DIGIT DRIVER FOR INTERFACING BETWEEN MOS AND LIGHT-EMITTING-DIODE (LED) DISPLAYS

- 50-mA Source or Sink Capability ('491, '491A)
- 250-mA Sink Capability ('492, '492A)
- Rated for 10-V Operation ('491, '492)
- Rated for 20-V Operation ('491A, '492A)
- Low Input Current for MOS Compatibility
- Low Standby Power
- High-Gain Darlington Circuits

description

The SN75491, SN75491A, SN75492, and SN75492A are monolithic integrated circuits designed to be used together with MOS integrated circuits and common-cathode LED's in serially addressed multi-digit displays. This time-multiplexed system, which uses a segment-address-and-digit-scan method of LED drive, minimizes the number of drivers required.

The SN75491 and SN75491A are quadruple segment drivers. The SN75492 and SN75492A are hex digit drivers. The SN75491 and SN75492 are characterized for operation to 10 volts. The SN75491A and SN75492A are characterized for operation to 20 volts.

The SN75491, SN75491A, SN75492, and SN75492A are characterized for operation from 0°C to 70°C.

DUAL-IN-LINE PACKAGE
(TOP VIEW)

description

The SN75494 is designed to be used as an interface between MOS integrated circuits and LEDs in serially addressed multidigit displays. This device is similar in operation to the SN75492, but has several advantages over the earlier circuit. The SN75494 can be operated at lower supply voltages therefore, reducing power consumption. The enable (\bar{E}) input is used as a blanking input.

logic symbol†

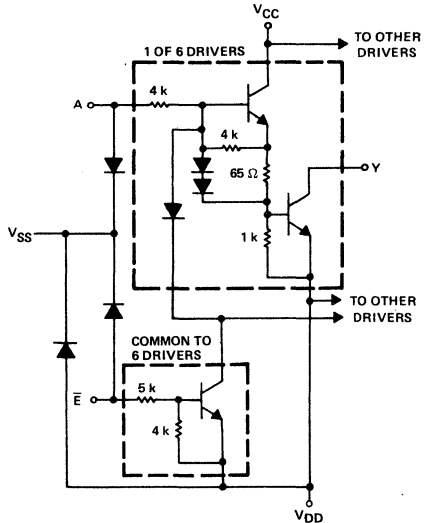

†This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

description

The SN55500E is a monolithic BIDFET† integrated circuit designed to perform the line select operation of a matrix-addressable display. The device inputs are diode-clamped CMOS inputs.

The outputs of the driver are normally low and can be selectively switched high when the strobe input is low. Selection of the outputs is achieved through the data, S0, and S1 inputs. The 8-bit data stored internally in the serial register is inverted and sent to one of four output sections by the 2-line to 4-line decoder. All other outputs remain low. Internal circuits provide a high-current pulse to the level-shifting circuit during positive output transitions. When the output transition is complete, the low steady-state current reduces the circuits stand-by power consumption. All outputs contain clamp diodes to the VCC2 and GND supply inputs.

The SN55500E is characterized for operation over the full military temperature range of -55°C to 125°C.

- Direct Replacement for SN55501C, SN55501D

description

The SN55501E is a monolithic BIDFET[†] integrated circuit designed to provide the serial-to-parallel conversion and level translation of data in a matrix-addressable display. This device has diode-clamped CMOS inputs.

The Q outputs of these drivers are normally high and can be switched either selectively or together. Any output whose associated register bit (in the internal 32-bit serial register) contains a low will switch low when the strobe input is switched low if the sustain input is high. All other outputs remain high. When the sustain input is switched low, all outputs switch low independently of the data or strobe inputs. This feature can be used to generate a portion of the sustain pulse required in the operation of an AC plasma display. The internal level-shift circuits provide additional drive during the times that the outputs switch high to facilitate fast rise times while maintaining low standby power consumption. All outputs contain clamp diodes to the VCC2 and GND supply inputs.

The SN55501E is characterized for operation over the full military temperature range of -55°C to 125°C.

- Dependable Texas Instruments Quality and Reliability

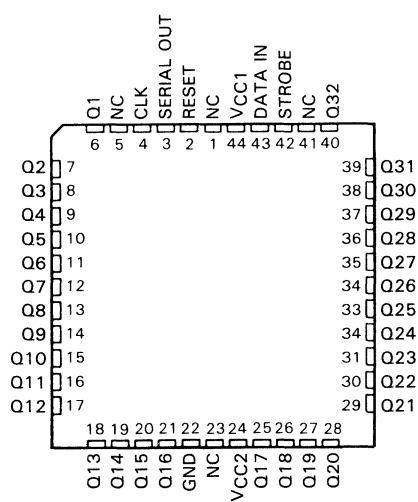

description

The SN65509 and SN75509 are monolithic BIDFET[†] integrated circuits designed to perform the line-select operation of a matrix-addressable display. All inputs are CMOS compatible and all outputs are totem-pole DMOS structures.

The 8-bit data stored internally in the serial register is transferred to one of four output sections selected by the last two bits entered into the 10-bit shift register. All 24 unselected outputs will remain at the high level while the state of the eight selected outputs will be set by the corresponding data in the shift register. VCC2 can be used as an output strobe as shown in typical operating sequence.

The SN65509 is characterized for operation from -40°C to 85°C. The SN75509 is characterized for operation from 0°C to 70°C.

- 25-mA Output Source Current Capability
- High-Speed Serially-Shifted Data Input
- TTL-Compatible Inputs
- Latches on All Driver Outputs

description

The SN65512B and SN75512B are monolithic BIFET[†] integrated circuits designed to drive a dot matrix or segmented vacuum fluorescent display.

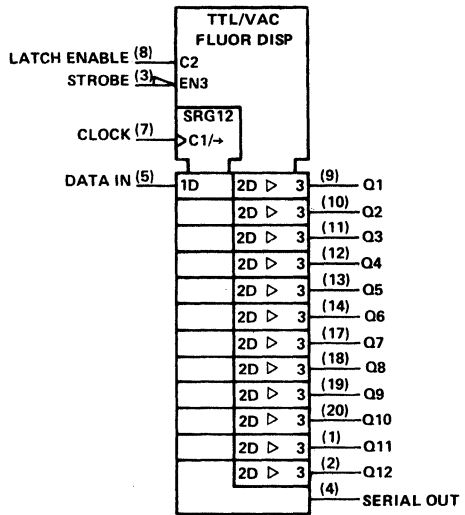

All device inputs are diode-clamped p-n-p inputs and will assume a high logic level when open-circuited. The nominal input threshold is 1.5 volts. Outputs are totem-pole structures formed by an n-p-n emitter follower and double-diffused MOS (DMOS) transistors.

The device consists of a 12-bit shift register, 12 latches, and 12 output AND gates. Serial data is entered into the shift register on the low-to-high transition of the Clock. When high, the Latch Enable input transfers the shift register contents to the outputs of the 12 latches. The active-low strobe input enables all Q outputs. Serial data output from the shift register may be used to cascade shift registers. This output is not affected by the Latch Enable or Strobe inputs.

The SN65512B is characterized for operation from -40°C to 85°C. The SN75512B is characterized for operation from 0°C to 70°C.

description

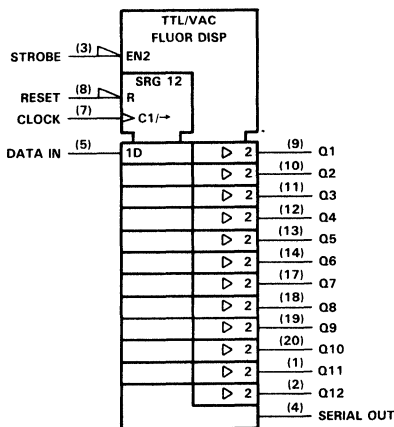

The SN65513B and SN75513B are monolithic BIFET[†] integrated circuits designed to drive a dot matrix or segmented vacuum fluorescent display.

All device inputs are diode-clamped p-n-p inputs and will assume a high logic level when left open. The nominal input threshold is 1.5 volts. Outputs are totem-pole structures formed by n-p-n emitter follower and double-diffused MOS (DMOS) transistors.

The device consists of a 12-bit shift register and 12 output AND gates. Data is entered into the shift register on the low-to-high transition of the Clock input. The active-low strobe input enables all Q outputs. The Reset input sets the shift register contents to all lows. The serial data output from the shift register may be used to cascade additional devices. This output is not affected by the strobe input.

The SN65513B is characterized for operation from -40°C to 85°C and the SN75513B is characterized for operation from 0°C to 70°C.

description

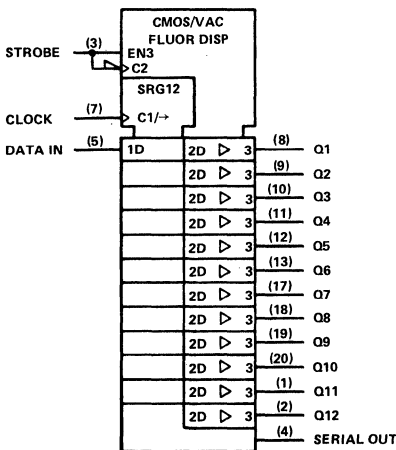

The SN75514 is a monolithic BIDFET[†] integrated circuit designed to drive a dot matrix or segmented vacuum fluorescent display. All device inputs are diode-clamped CMOS compatible inputs. The outputs are totem-pole structures formed with double-diffused MOS (DMOS) transistors.

The device consists of a 12-bit shift register, a 12-bit storage register, and 12 output AND gates. Serial data is entered into the shift register on the low-to-high transition of the clock input. On the high-to-low transition of the strobe input, data is transferred from the shift registers to the latches. When Strobe goes high, all Q outputs are enabled. Serial data output from the shift register may be used to cascade additional devices. Serial Out is not affected by the Strobe input.

Supply voltage VCC2 and VCC3 are used to provide 25-milliampere output source current capability at acceptable static device power dissipation. In this mode of operation VCC3 should be equal to VCC2 + 10 volts. It is possible to operate this device with VCC3 = VCC2. However, the current capability will be reduced.

The SN75514 is characterized for operation from 0°C to 70°C.

SN65518, SN75518 VACUUM FLUORESCENT DISPLAY DRIVERS

D2720, MARCH 1983—REVISED OCTOBER 1986

- Each Device Drives 32 Lines
- 60-V Output Voltage Swing Capability
- 25-mA Output Source Current Capability
- High-Speed Serially Shifted Data Input
- Latches on All Driver Outputs

description

The SN65518 and SN75518 are monolithic BIFDET[†] integrated circuits designed to drive a dot matrix or segmented vacuum fluorescent display.

The devices each consist of a 32-bit shift register, 32 latches, and 32 output AND gates. Serial data is entered into the shift register on the low-to-high transition of the clock input. While the Latch Enable input is high, parallel data is transferred to the output buffers through a 32-bit latch. Data present in the latch during the high-to-low transition of Latch Enable is latched. When the Strobe input is low, all Q outputs are enabled. When the Strobe input is high, all Q outputs are low.

Serial data output from the shift register may be used to cascade additional devices. This output is not affected by the Latch Enable or Strobe inputs.

The SN65518 is characterized for operation from -40°C to 85°C and the SN75518 is characterized for operation from 0°C to 70°C.

SN55551, SN55552 ELECTROLUMINESCENT ROW DRIVER

D2743, APRIL 1986

- Each Device Drives 32 Electrodes
- High-Voltage Open-Drain DMOS Outputs
- 50-mA Output Current Capability
- CMOS-Compatible Inputs
- Very Low Steady-State Power Consumption

description

The SN55551 and SN55552 are monolithic BIDFET[†] integrated circuits designed to drive the row electrodes of an electroluminescent display. All inputs are CMOS-compatible and all outputs are high-voltage open-drain DMOS transistors. The SN55552 output sequence has been reversed from the SN55551 for ease in printed circuit board layout.

The devices consist of a 32-bit shift register, 32 AND gates, and 32 output OR gates. Typically, a composite row drive signal is externally generated by a high-voltage switching circuit and applied to the Substrate Common terminal. Serial data is entered into the shift register on the high-to-low transition of the clock input. A high Enable input allows those outputs with a high in their associated register to be turned on causing the corresponding row to be connected to the composite row drive signal. When the Strobe input is low, all output transistors are turned on. The Serial Data output from the shift register may be used to cascade additional devices. This output is not affected by the Enable or Strobe inputs.

The SN55551 and SN55552 are characterized for operation over the full military temperature range of -55°C to 125°C.

- 15-mA Output Source and Sink Current Capability
- High-Speed Serially-Shifted Data Input
- Totem-Pole Outputs
- Latches on All Driver Outputs

description

The SN55553 and SN55554 are monolithic BIFET[†] integrated circuits designed to drive the column electrodes of an electroluminescent display. The SN55554 output sequence has been reversed from the SN55553 for ease in printed circuit board layout.

The devices consist of a 32-bit shift register, 32 latches, and 32 output AND gates. Serial data is entered into the shift register on the low-to-high transition of the clock input. When high, the Latch Enable input transfers the shift register contents to the outputs of the 32 latches. When Output Enable is high, all Q outputs are enabled. Serial data output from the shift register may be used to cascade shift registers. This output is not affected by the Latch Enable or Output Enable inputs.

The SN55553 and SN55554 are characterized for operation over the full military temperature range of -55°C to 125°C.

D2999, DECEMBER 1985

- Each Device Drives 32 Electrodes
- High-Voltage Open-Collector N-P-N Outputs Using Ramped Supply
- 300-mA Output Current Capability
- CMOS-Compatible Inputs
- Very Low Steady-State Power Consumption

description

These devices are monolithic BIFDET[†] integrated circuits designed to drive the row electrodes of an electroluminescent display. All inputs are CMOS-compatible and all outputs are high-voltage open-collector n-p-n transistors. The SN65558 and SN75558 output sequences have been reversed from the SN65557 and SN75557 for ease in printed circuit board layout.

The devices consist of a 32-bit shift register, 32 AND gates, and 32 output OR gates. Typically, a composite row drive signal is externally generated by a high-voltage switching circuit and applied to the Substrate Common terminal. Serial data is entered into the shift register on the high-to-low transition of the clock input. A high Enable input allows those outputs with a high in their associated register to be turned on causing the corresponding row to be connected to the composite row drive signal. When the Strobe input is low, all output transistors are turned on. The Serial output from the shift register may be used to cascade additional devices. This output is not affected by the Enable or Strobe inputs.

The SN65557 and SN65558 are characterized for operation from -40°C to 85°C. The SN75557 and SN75558 are characterized for operation from 0°C to 70°C.

description

The SN65559, SN65560, SN75559, and SN75560 are monolithic BIDFET† integrated circuits designed to provide the serial-to-parallel conversion and level translation of data in a matrix-addressable electroluminescent display. The device inputs are diode-clamped CMOS inputs. The SN65560 and SN75560 output sequences are reversed from the SN65559 and SN75559 for ease in printed circuit board layout.

These column drivers consist of a 32-bit static shift register, 32 latches, and 32 high-voltage outputs. Serial data is entered into the shift register on the low-to-high transition of the clock signal. A logic high signal on the Latch Enable input transfers the data from the shift register to the latches while the VCC2 bus is low. Once stable in the latch circuits, the VCC2 rail is ramped up to allow the data to appear at the high-voltage outputs. By limiting VCC2 to a maximum of 60 volts, these devices may be safely operated in a non-ramped VCC2 mode. Drivers may be cascaded via the serial data output of the static shift register. This output is not affected by the Latch Enable input.

The SN65559 and SN65560 are characterized for operation from -40°C to 85°C. The SN75559 and SN75560 are characterized for operation from 0°C to 70°C.

description

The SN65563, SN65564, SN75563, and SN75564 are monolithic BIFET[†] integrated circuits designed to drive the row electrodes of an electroluminescent display. All inputs are CMOS compatible. If the Positive Write input is high, the Q outputs act like open-source outputs and output data is not inverted with respect to input data. If the Positive Write input is low, the Q outputs act like open-drain outputs and output data is inverted with respect to input data. The SN65564 and SN75564 output sequences have been reversed from the SN65563 and SN75563 for ease in printed circuit board layout.

Typically, composite VCC2 and ground signals are externally generated by a high-voltage switching circuit. Serial data is entered into the shift register on the high-to-low transition of the clock input. A high Enable input allows those outputs with a high in their associated register to be turned on causing the corresponding row to be connected to VCC2 when Positive Write is high or to ground when Positive Write is low. The Serial Output from the shift register may be used to cascade additional devices. This output is not affected by the Enable or Positive Write inputs.

The SN65563 and SN65564 are characterized for operation over the full automotive operating temperature range of -40°C to 85°C. The SN75563 and SN75564 are characterized for operation from 0°C to 70°C.

description

The SN65567, SN65568, SN75567, and SN75568 are monolithic BIDFET[†] integrated circuits designed to provide the serial-to-parallel conversion and level translation of data in a matrix-addressable electroluminescent display. The device inputs are diode-clamped CMOS inputs. The SN65568 and SN75568 output sequences are reversed from the SN65567 and SN75567 for ease in printed circuit board layout.

These column drivers consist of two 16-bit static shift registers, 32 latches, and 32 high-voltage outputs. Typically, a 32-bit data string is split into two 16-bit data strings externally and then entered in parallel into the shift registers on the low-to-high transition of the clock signal. The register associated with Data Input 1 loads the odd bits while the shift register associated with Data Input 2 loads the even bits of the 32 latches. This method of entering data effectively doubles the clock frequency of a 32-bit shift register. A logic high signal on the latch enable input transfers the data from the shift register to the latches while the VCC2 bus is low. Once stable in the latch circuits, the VCC2 rail is ramped up to allow the data to appear at the high-voltage outputs. By limiting VCC2 to a maximum of 50 volts, these devices may be safely operated in a non-ramped VCC2 mode. Drivers may be cascaded via the serial data outputs of the static shift registers. These outputs are not affected by the latch enable input.

The SN65567 and SN65568 are characterized for operation from -40°C to 85°C. The SN75567 and SN75568 are characterized for operation from 0°C to 70°C.

NC—No internal connection

description

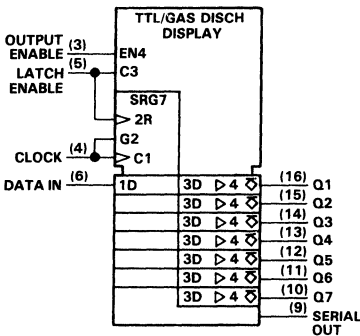

The SN75581 is a monolithic BIFET[†] integrated circuit designed to drive a dot matrix or segmented display. The output characteristics of this driver make it compatible to several display types including VF and DC plasma displays.

All device inputs are diode-clamped p-n-p inputs and, when left open, assume a high-logic level. The nominal input threshold is 1.5 volts. Outputs are open-source DMOS transistors for excellent high-voltage characteristics and reliability.

The device consists of a 7-bit shift register, seven latches, and seven output AND gates. Serial data is entered into the shift register on the low-to-high transition of the Clock input. When the Latch Enable input is high, data is transferred from the shift registers to the latch outputs. When Latch Enable makes a high-to-low transition with the Clock input high, the shift register is cleared. Taking the Output Enable input high enables all Q outputs simultaneously. The Serial Output is not affected by the Output Enable input.

The SN75581 is characterized for operation from 0°C to 70°C.

description

The SN751506 and the SN751516 are monolithic integrated circuits designed to drive the scan lines of a dc plasma panel display. The SN751516 pin sequence is reversed from the SN751506 for ease in printed circuit board layout.

Each device consists of a 32-bit shift register and 32 OR gates. Serial data is entered into the shift register on the high-to-low transition of the clock input. When the strobe input is low, all Q outputs are in the off-state. Outputs are open-drain JFET transistors with a breakdown voltage in excess of 180 volts. The outputs have a 220-milliampere sink current capability in the on state. Only one Q output should be allowed to be in the on state at a time.

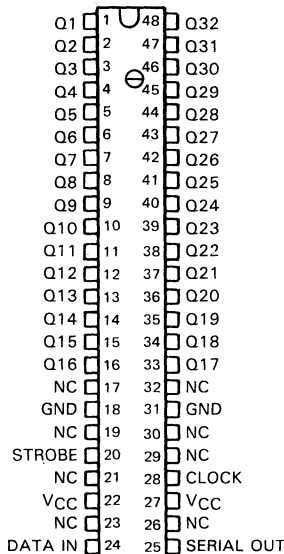

Serial data output from the shift register may be used to cascade shift registers. This output is not affected by the strobe input. All inputs are CMOS compatible with ESD protection built in.

The SN751506 and SN751516 are characterized for operation from 0°C to 70°C.

description

The SN751508 and SN751518 are monolithic integrated circuits designed to drive the data lines of a dc plasma panel display. The SN751518 pin sequence is reversed from the SN751508 for ease in printed circuit board layout.

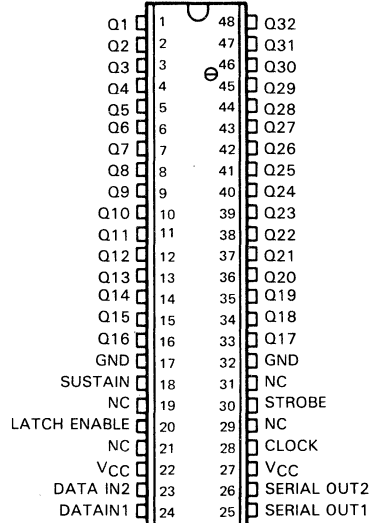

Each device consists of two 16-bit shift registers, 32 latches, 32 OR gates, and 32 P-N-P open-collector output AND gates. Typically, a 32-bit data string is split into two 16-bit data strings externally and then entered in parallel into the shift registers on the high-to-low transition of the clock signal. A logic high signal on the Latch Enable input transfers the data from the shift registers to the inputs of 32 OR gates through the latches. Data present in the latch during the high-to-low transition of Latch Enable is stored. When the Strobe input is high, the latch is masked and a high will be placed on the data input of the output AND gates. When the Strobe input is low, and the Sustain input is high, data from the latches is reflected at the outputs. A logic low signal on the Sustain input will force all outputs to their off state. Drivers may be cascaded via the serial data outputs of the static shift registers. These outputs are not affected by the Latch Enable, Strobe, or Sustain inputs.

The SN751508 and the SN751518 are characterized from 0°C to 70°C.

TL4810BI, TL4810B VACUUM FLUORESCENT DISPLAY DRIVERS

D2715, DECEMBER 1984—REVISED FEBRUARY 1986

- Each Device Drives 10 Lines
- 60-V Output Voltage Rating
- 40-mA Output Source Current
- High-Speed Serially-Shifted Data Input
- CMOS-Compatible Inputs
- Latches on All Driver Outputs
- Improved Direct Replacement for UCN4810A and TL4810A

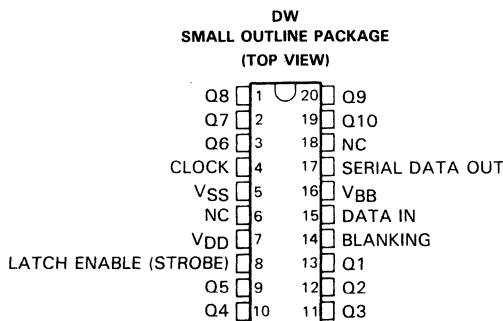

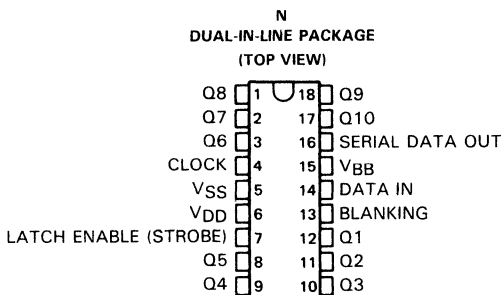

description

The TL4810BI and TL4810B are monolithic BIFET[†] integrated circuits designed to drive a dot matrix or segmented vacuum fluorescent display (VFD). These devices feature a serial data output to cascade additional devices for large display arrays.

A 10-bit data word is serially loaded into the shift register on the positive-going transitions of the clock. Parallel data is transferred to the output buffers through a 10-bit D-type latch while the latch enable input is high and is latched when the latch enable is low. When the blanking input is high, all outputs are low.

Outputs are totem-pole structures formed by n-p-n emitter-follower and double-diffused MOS (DMOS) transistors with output voltage ratings of 70 volts and 40 milliamperes source-current capability. All inputs are compatible with CMOS and TTL levels, but each requires the addition of a pull-up resistor to V_{DD} when driven by TTL logic.

The TL4810BI is characterized for operation from -40°C to 85°C. The TL4810B is characterized for operation from 0°C to 70°C.

description

The TL5812I and TL5812 are monolithic BIFET[†] integrated circuits designed to drive a dot matrix or segmented vacuum fluorescent display (VFD). Each device features a serial data output to cascade additional devices for large display arrays.

A 20-bit data word is serially loaded into the shift register on the low-to-high transition of the clock input. Parallel data is transferred to the output buffers through a 20-bit D-type latch while the Latch Enable input is high and is latched when the Latch Enable input is low. When the blanking input is high, all outputs are low.

The outputs are totem-pole structures formed by n-p-n emitter-follower and double-diffused MOS (DMOS) transistors with output voltage ratings of 70 volts and a source-current capability of 40 milliamperes. All inputs are CMOS compatible.

The TL5812I is characterized for operation from -40°C to 85°C. The TL5812 is characterized for operation from 0°C to 70°C.

AM26LS31M, AM26LS31C QUADRUPLE DIFFERENTIAL LINE DRIVERS

D2433, JANUARY 1979—REVISED OCTOBER 1986

- Meets EIA Standard RS-422-A
- Operates from a Single 5-V Supply
- TTL Compatible
- Complementary Outputs
- High Output Impedance in Power-Off Conditions
- Complementary Output Enable Inputs

description

The AM26LS31M and AM26LS31C are quadruple complementary-output line drivers designed to meet the requirements of EIA Standard RS-422-A and Federal Standard 1020. The three-state outputs have high-current capability for driving balanced lines such as twisted-pair or parallel-wire transmission lines, and they provide a high-impedance state in the power-off condition. The enable function is common to all four drivers and offers the choice of an active-high or active-low enable input. Low-power Schottky circuitry reduces power consumption without sacrificing speed.

The AM26LS31M is characterized for operation over the full military temperature range of -55°C to 125°C . The AM26LS31C is characterized for operation from 0°C to 70°C .

PARAMETER MEASUREMENT INFORMATION

PROPAGATION DELAY TIMES AND SKEW

ENABLE AND DISABLE TIMES

VOLTAGE WAVEFORMS

TEST CIRCUIT

- NOTES: A. All input pulses are supplied by generators having the following characteristics: $PRR \leq 1 \text{ MHz}$, $Z_{out} \approx 50 \Omega$, $t_r \leq 15 \text{ ns}$, and $t_f \leq 6 \text{ ns}$.
 B. When measuring propagation delay times and skew, switches S1 and S2 are open.
 C. Each enable is tested separately.
 D. Waveform 1 is for an output with internal conditions such that the output is low except when disabled by the output control. Waveform 2 is for an output with internal conditions such that the output is high except when disabled by the output control.
 E. C_L includes probe and jig capacitance.

AM26LS32AM, AM26LS33AM, AM26LS32AC, AM26LS33AC QUADRUPLE DIFFERENTIAL LINE RECEIVERS

D2434, OCTOBER 1980—REVISED SEPTEMBER 1986

- AM26LS32A Meets EIA Standards RS-422-A and RS-423-A
- AM26LS32A has ± 7 -V Common-Mode Range with ± 200 -mV Sensitivity
- AM26LS33A has ± 15 -V Common-Mode Range with ± 500 mV Sensitivity
- Input Hysteresis . . . 50 mV Typical
- Operates from a Single 5-V Supply
- Low-Power Schottky Circuitry
- 3-State Outputs
- Complementary Output Enable Inputs
- Input Impedance . . . 12 k Ω Min
- Designed to be Interchangeable with Advanced Micro Devices AM26LS32C and AM26LS33C

description

The AM26LS32A and AM26LS33A are quadruple line receivers for balanced and unbalanced digital data transmission. The enable function is common to all four receivers and offers a choice of active-high or active-low input. Three-state outputs permit connection directly to a bus-organized system. Fail-safe design ensures that if the inputs are open, the outputs will always be high.

Compared to the AM26LS32C and the AM26LS33C, the AM26LS32A and AM26LS33A incorporate an additional stage of amplification to improve sensitivity. The input impedance has been increased resulting in less loading of the bus line. The additional stage has increased propagation delay; however, this will not affect interchangeability in most applications.

The AM26LS32AM and the AM26LS33AM are characterized for operation over the full military temperature range of -55°C to 125°C . The AM26LS32AC and AM26LS33AC are characterized for operation from 0°C to 70°C .

description

The AM26S10 and AM26S11 are quadruple bus transceivers utilizing Schottky-diode-clamped transistors for high speed. The drivers feature open-collector outputs capable of sinking 100 mA at 0.8 V maximum. The driver and strobe inputs use p-n-p transistors to reduce the input loading.

The driver of the AM26S10 is inverting; the driver of the AM26S11 is noninverting. Each device has two ground connections for improved ground current-handling capability. For proper operation, the ground pins should be tied together.

The AM26S10M and AM26S11M are characterized for operation over the full military temperature range of -55°C to 125°C . The AM26S10C and AM26S11C are characterized for operation over the temperature range of 0°C to 70°C .

MC3446 QUADRUPLE BUS TRANSCEIVER

D2290, JANUARY 1977 - REVISED SEPTEMBER 1986

- Driver Inputs Compatible with TTL and MOS Circuitry
- Driver Outputs Stay Off During Power Up and Power Down
- Drivers Feature Open-Collector Outputs for Party-Line Operation
- Designed for Interchangeability with Motorola MC3446
- Meet IEEE Standard 488-1975

D, J, OR N DUAL-IN-LINE PACKAGE
(TOP VIEW)

description

These circuits are quadruple single-ended line transceivers designed for bidirectional flow of data and instructions. The bus terminal characteristic complies with paragraph 3.5.3 of IEEE Standard 488 (see Figure 3). Each driver output is tied to the junction of an internal voltage divider that sets the no-load output voltage and provides bus termination. The driver outputs are guaranteed to be "off" during power up and power down if either input is high. The receivers feature 950 millivolts typical hysteresis for noise immunity.

The MC3446 is characterized for operation from 0°C to 70°C.

- Glitch-Free Power-Up/Power-Down Operation

D, J, OR N PACKAGE
(TOP VIEW)

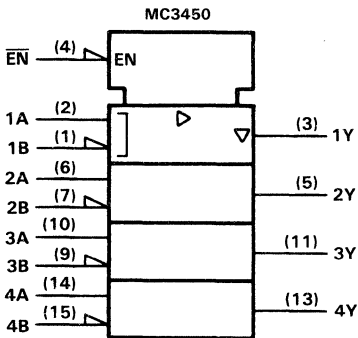

description

The MC3450 and MC3452 are quadruple differential line receivers designed for use in balanced and unbalanced digital data transmission. The MC3450 and MC3452 are the same except that the MC3450 has three-state outputs whereas the MC3452 has open-collector outputs, which permit the wire-AND function with similar output devices. Three-state and open-collector outputs permit connection directly to a bus-organized system.

The MC3450 and MC3452 are designed for optimum performance when used with either the MC3453 quadruple differential line driver or SN75109A, SN75110A, and SN75112 dual differential drivers.

The MC3450 and MC3452 are characterized for operation from 0°C to 70°C.

Line Drivers/Receivers

MC3453 QUADRUPLE LINE DRIVER WITH COMMON ENABLE

D3000, FEBRUARY 1986

- Similar to a Dual Version of SN75110A Line Driver
- Improved Stability Over Supply Voltage and Temperature Ranges
- Constant-Current Outputs
- High Output Impedance
- High Common-Mode Output Voltage Range (-3 V to 10 V)
- Glitch-Free Power-Up/Power-Down Operation
- TTL Input Compatibility
- Common Enable Circuit
- Designed to be Interchangeable with Motorola MC3453

description

The MC3453 features four line drivers with a common enable input. When the enable input is high, a constant output current is switched between each pair of output terminals in response to the logic level at that channel's input. When the enable is low, all channel outputs are nonconductive (transistors biased to cutoff). This minimizes loading in party-line systems where a large number of drivers share the same line.

The driver outputs have a common-mode voltage range of -3 volts to 10 volts, allowing common-mode voltages on the line without affecting driver performance.

All inputs are diode clamped and are designed to satisfy TTL-system requirements. The inputs are tested at 2 volts for high-logic-level input conditions and 0.8 volt for low-logic-level input conditions. These tests guarantee 400 millivolts of noise margin when interfaced with Series 54/74 TTL.

The MC3453 is characterized for operation from 0°C to 70°C.

MC3486

QUADRUPLE LINE RECEIVER WITH 3-STATE OUTPUT

D2434, JUNE 1980—REVISED SEPTEMBER 1986

- Meets EIA Standards RS-422-A and RS423-A and Federal Standards 1020 and 1030
- Three-State, TTL-Compatible Outputs
- Fast Transition Times
- Operates from Single 5-Volt Supply
- Designed to be Interchangeable with Motorola MC3486

D, J OR N PACKAGE
(TOP VIEW)

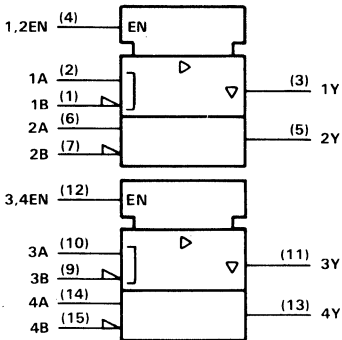

description

The MC3486 is a monolithic quadruple differential line receiver designed to meet the specifications of EIA Standards RS-422-A and RS-423-A and Federal Standards 1020 and 1030. The MC3486 offers four independent differential-input line receivers that have TTL-compatible outputs. The outputs utilize three-state circuitry to provide a high-impedance state at any output when the appropriate output enable is at a low logic level.

The MC3486 is designed for optimum performance when used with the MC3487 quadruple differential line driver. It is supplied in a 16-pin package and operates from a single 5-volt supply.

The MC3486 is characterized for operation from 0°C to 70°C.

- Single 5-Volt Supply
- Power-Up and Power-Down Protection
- Designed to be Interchangeable with Motorola MC3487

D, J, OR N DUAL-IN-LINE PACKAGE
(TOP VIEW)

description

The MC3487 offers four independent differential line drivers designed to meet the specifications of EIA Standard RS-422-A and Federal Standard 1020. Each driver has a TTL-compatible input buffered to reduce current and minimize loading.

The driver outputs utilize 3-state circuitry to provide high-impedance states at any pair of differential outputs when the appropriate output enable is at a low logic level. Internal circuitry is provided to ensure a high-impedance state at the differential outputs during power-up and power-down transition times, provided the output enable is low. The outputs are capable of source or sink currents of 48 milliamperes.

The MC3487 is designed for optimum performance when used with the MC3486 quadruple line receiver. It is supplied in a 16-pin dual-in-line package and operates from a single 5-volt supply.

The MC3487 is characterized for operation from 0°C to 70°C.

N8T26 QUADRUPLE BUS TRANSCIVER WITH 3-STATE OUTPUTS

D2462, MAY 1978—REVISED SEPTEMBER 1986

- P-N-P Inputs for Minimal Input Loading (200 μ A Maximum)
- High-Speed Schottky Circuitry
- 3-State Outputs for Driver and Receiver
- Party-Line (Data-Bus) Operation
- Single 5-V Supply
- Designed to be Interchangeable with Signetics N8T26, also Called 8T26

D, J, OR N PACKAGE
(TOP VIEW)

description

The N8T26 is a quadruple transceiver utilizing Schottky-diode-clamped transistors. Both the driver and receiver have three-state outputs. With p-n-p inputs, the input loading is reduced to a maximum input current of 200 microamperes. This device is capable of high switching rates into high-capacitance loads and are suitable for driving long bus lines.

The N8T26 is characterized for operation from 0°C to 70°C.

FUNCTION TABLE (DRIVER)

INPUT		OUTPUT

DW, J, OR N PACKAGE
(TOP VIEW)

PIN		DESCRIPTION
NAME	NUMBER	
DATEN	15	Driver Data Enable. When low, places driver outputs in an active state. When high, the driver outputs are in a high-impedance state if DLEN is also high.
DLEN	13	Driver Delay Enable. When this signal is low and DATEN is high, the driver outputs are active for a period of time set by DRDLAJ after a positive-going transition on DRI. If there is no active data on DRI, the outputs are in a high-impedance state.
DRDLAJ	1	Driver Delay Adjust is a connection for the external R-C combination that determines the duration of the driver output active state after a positive transition on DRI when DLEN is low and DATEN is high.
DRI	14	Driver Data Input
DRO+	2	Noninverting Driver Output
DRO-	3	Inverting Driver Output
GND	8	Ground. Common for all voltages
RXI+	5	Noninverting Receiver Input
RXI-	6	Inverting Receiver Input
RXO	12	Main Receiver Output
SQDLAJ	4	Squelch Delay Adjust is a connection for an external R-C combination that determines the duration of the receiver unsquelch after a negative-going transition on SQDLI.
SQDLI	10	Squelch Delay Input is the input to the one-shot that controls the duration of the receiver unsquelch period. The main receiver output remains unsquelched as long as SQDLI is held high. Timing of the unsquelch period begins on the high-to-low transition of SQDLI.
SQO	11	Squelch Output is high while the receiver is squelched.
SQRXO	9	Squelch Receiver Output is high only when the differential receiver input exceeds the threshold set by SQTHAJ.
SQTHAJ	7	Squelch Receiver Threshold Adjust. The voltage at this input determines the threshold of the squelch receiver in a ratio of -2, SQTHAJ to threshold. If left open, the squelch receiver threshold defaults to -600 mV.
VCC	16	Supply voltage input

FUNCTION TABLES

DRIVER					
INPUTS			OUTPUTS		
DRIVER IN	DATA ENABLE	DELAY ENABLE	OUTPUT +	OUTPUT -	
L	L	X	L	H	
H	L	X	H	L	
X	H	H	Z	Z	
H	H	L	H [†]	L [†]	
L	H	L	L [‡]	H [‡]	

RECEIVER [§]				
CONDITION	INPUTS		OUTPUTS	
	IN +	IN -	RECEIVER OUT	SQUELCH THRESHOLD
No active signal [¶]	X	X	H	H
Active signal [¶]	L	H	L	L
	H	L	H	L

[†] This condition is valid during the time period set by Driver Delay Adjust following a rising transition on Driver In. Following this, if no subsequent positive transition occurs on Driver In, the outputs will go to the high impedance state.

[‡] This condition is valid if it occurs within the enable time set by Driver Delay Adjust after a rising transition on Driver In. Otherwise, the outputs will be in the high-impedance state.

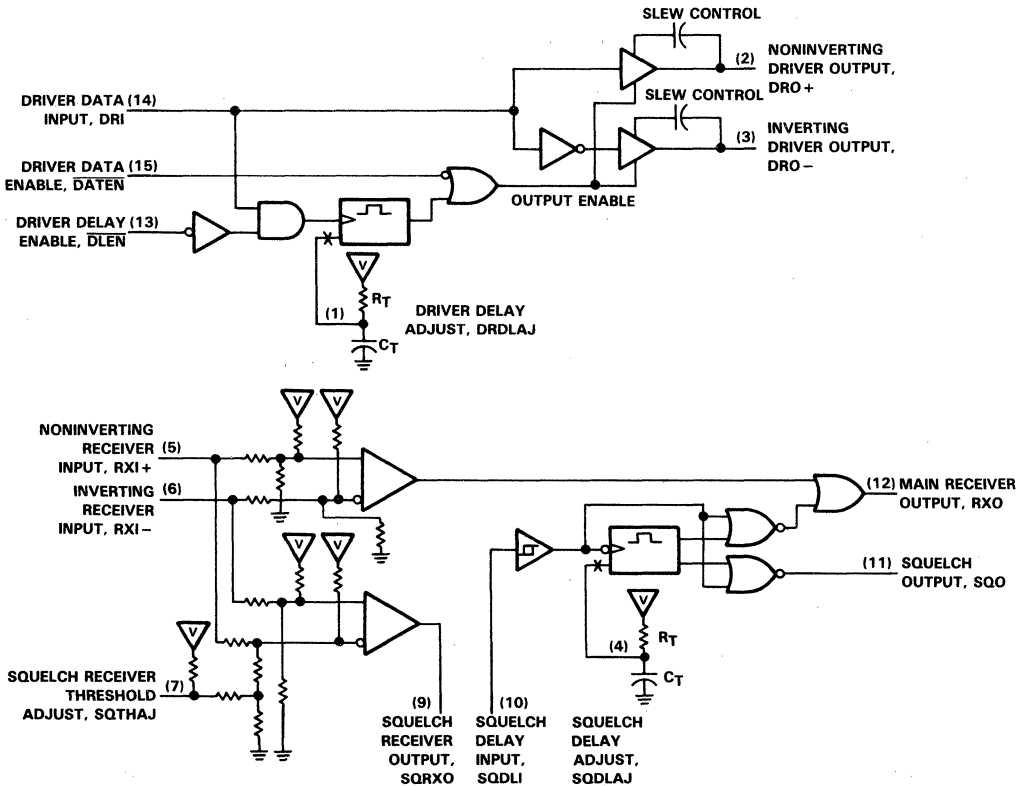

[§] Pins 9 and 10 are tied together.

[¶] An active signal is one that has an amplitude greater than the threshold level set by Squelch Threshold Adjust.

Line Drivers/Receivers

logic diagram (positive logic)

ADVANCE INFORMATION

description

The SN75061 is a single-channel driver/receiver pair designed for use in IEEE 802.3, 1BASE5 applications as well as other general data communications circuits. The SN75061 offers the system designer both a driver and a receiver that are easily configured for use with a variety of controllers and data encoder/decoders.

The receiver features a full analog squelch circuit with an adjustable threshold and a programmable squelch delay. Internal nodes of the squelch circuitry are brought out to external connections to allow for the insertion of noise filtering circuitry of the designer's choice.

As with the receiver, the driver offers the user a variety of implementation options. Driver enabling may be controlled directly by an external logic input, or by use of an on-chip one-shot that is retrigged as long as data is being sent to the driver. The driver will then automatically go to the high-impedance state when end-of-packet occurs. The driver features internal slew-rate control for optimal matching of rise and fall times allowing for reduction of driver-induced jitter.

receiver

The SN75061 receiver implements full analog squelch functions by integrating both a separate, parallel squelch receiver with an externally programmable threshold, and a programmable one-shot. The output of the squelch receiver and the input to the high-level dc-triggered one-shot are brought out to external connections. These pins can be shorted for direct implementation, or used for the insertion of noise-filtering circuitry of the implementer's design. The receiver one-shot can be effectively bypassed by applying a high logic level to Squelch Delay In. The squelch threshold may be set externally by applying an external voltage set to a level that is -2 times the desired threshold voltage. If Squelch Threshold Adjust is left open, the squelch receiver will default to its internal preset value of -600 millivolts. The receiver also outputs a high logic "squelch" signal when there is no active data present at the receiver inputs. When no data is present on the transmission line, the receiver output assumes a high level. The "unsquelch" duration is set externally with an R-C combination at Squelch Delay Adjust.

driver

The driver offers the user a variety of implementation options. Driver enabling may be controlled directly by an active-low external logic input on Data Enable, or by use of another on-chip one-shot that retriggers with positive-going transitions on the driver input line. If no positive transition occurs within the pulse duration set by an external R-C combination, the one-shot times out and the driver is automatically put into a high-impedance state. When operating in the delay-enable mode, the 2-bit-time high-level start-of-idle pulse prescribed by IEEE 802.3 1BASE5 causes the one-shot to time out and automatically place the driver outputs in the high-impedance state. This delay time is also adjustable for use in other applications.

The driver implements an output slew-rate control that is internally set for nominally 40 mV/ns. (This is roughly a 100-ns peak-to-peak differential transition time.) The driver outputs are capable of driving a 50-ohm differential load with a guaranteed minimum output level of 2 volts. Short-circuit output current is guaranteed to be greater than 100 milliamperes.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC}	7 V
Input voltage (any logic input)	7 V
Receiver differential input voltage	± 25 V
Receiver input voltage	± 15 V
Driver output voltage	-0.5 V to 15 V
Continuous total dissipation at (or below) 25°C free-air temperature (see Note 1):	
DW or J package	1025 mW
N package	1150 mW
Operating free-air temperature range	0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds: J package	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: DW or N package	260°C

NOTE 1: For operation above 25°C free-air temperature, derate the DW and J packages to 656 mW at 70°C at the rate of 8.2 mW/°C, and the N package to 736 mW at 70°C at the rate of 9.2 mW/°C.

recommended operating conditions

	MIN	NOM	MAX	UNIT
Supply voltage, V_{CC}	4.75	5	5.25	V
Driver high-level input voltage, V_{IH}	2			V
Driver low-level input voltage, V_{IL}			0.8	V
Driver high-level output current, I_{OH}			-150	mA
Driver low-level output current, I_{OL}			150	mA
Receiver common-mode input voltage, V_{IC} (see Note 2)	-2.5		5	V
External timing resistance, R_{ext}	5		260	k Ω
External timing capacitance, C_{ext}	No restriction			
Operating free-air temperature, T_A	0		70	°C

NOTE 2: The algebraic convention, in which the less positive (more negative) limit is designated as minimum, is used in this data sheet for common-mode input voltage V_{IC} and threshold levels V_{TH} and V_{TL} .

D2304, JANUARY 1977—REVISED OCTOBER 1986

- High Speed
- Standard Supply Voltage
- Dual Channels
- High Common-Mode Rejection Ratio
- High Input Impedance
- High Input Sensitivity
- Differential Input Common-Mode Range of ± 3 V
- Strobe Inputs for Receiver Selection
- Gate Inputs for Logic Versatility
- TTL Drive Capability
- High DC Noise Margin
- '107A and '107B Have Totem-Pole Outputs
- '108A and '108B Have Open-Collector Outputs
- "B" Versions Have Diode-Protected Input for Power-Off Condition

description

These circuits are TTL-compatible high-speed line receivers. Each is a monolithic dual circuit featuring two independent channels. They are designed for general use as well as such specific applications as data comparators and balanced, unbalanced, and party-line transmission systems. These devices are unilaterally interchangeable with and are replacements for the SN55107, SN55108, SN75107, and SN75108, but offer diode-clamped strobe inputs to simplify circuit design.

The essential difference between the "A" and "B" versions can be seen in the schematics. Input-protection diodes are in series with the collectors of the differential-input transistors of the "B" versions. These diodes are useful in certain "party-line" systems that may have multiple V_{CC+} power supplies and may be operated with some of the V_{CC+} supplies turned off. In such a system, if a supply is turned off and allowed to go to ground, the equivalent input circuit connected to that supply would be as follows:

This would be a problem in specific systems that might possibly have the transmission lines biased to some potential greater than 1.4 volts.

The SN55107A, SN55107B, SN55108A, and SN55108B are characterized for operation over the full military temperature range of -55°C to 125°C . The SN75107A, SN75107B, SN75108A, and SN75108B are characterized for operation from 0°C to 70°C .

TYPICAL APPLICATION LINE DATA

basic balanced-line transmission system

The '107A, '107B, '108A, and '108B dual line circuits are designed specifically for use in high-speed data transmission systems that utilize balanced, terminated transmission lines such as twisted-pair lines. The system operates in the balanced mode, so noise induced on one line is also induced on the other. The noise appears common-mode at the receiver input terminals where it is rejected. The ground connection between the line driver and receiver is not part of the signal circuit so that system performance is not affected by circulating ground currents.

The unique driver-output circuit allows terminated transmission lines to be driven at normal line impedances. High-speed system operation is ensured since line reflections are virtually eliminated when terminated lines are used. Crosstalk is minimized by low signal amplitudes and low line impedances.

The typical data delay in a system is approximately $(30 + 1.3 L)$ nanoseconds, where L is the distance in feet separating the driver and receiver. This delay includes one gate delay in both the driver and receiver.

Data is impressed on the balanced-line system by unbalancing the line voltages with the driver output current. The driven line is selected by appropriate driver-input logic levels. The voltage difference is approximately:

$$V_{DIFF} \approx 1/2 I_{O(on)} \cdot R_T$$

High series line resistance will cause degradation of the signal. The receivers, however, will detect signals as low as 25 mV (or less). For normal line resistances, data may be recovered from lines of several thousand feet in length.

Line-termination resistors (R_T) are required only at the extreme ends of the line. For short lines, termination resistors at the receiver only may prove adequate. The signal amplitude will then be approximately:

$$V_{DIFF} \approx I_{O(on)} \cdot R_T$$

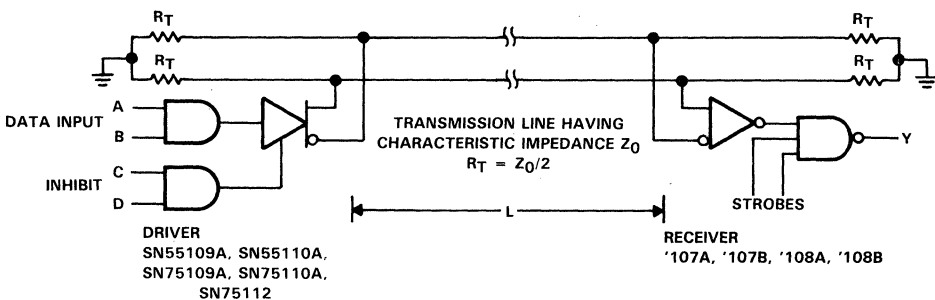

FIGURE 10

data-bus or party-line system

The strobe feature of the receivers and the inhibit feature of the drivers allow these dual line circuits to be used in data-bus or party-line systems. In these applications, several drivers and receivers may share a common transmission line. An enabled driver transmits data to all enabled receivers on the line while other drivers and receivers are disabled. Data is thus time-multiplexed on the transmission line. The device specifications allow widely varying thermal and electrical environments at the various driver and receiver locations. The data-bus system offers maximum performance at minimum cost.

4

Line Drivers/Receivers

unbalanced or single-line systems

These dual line circuits may also be used in unbalanced or single-line systems. Although these systems do not offer the same performance as balanced systems for long lines, they are adequate for very short lines where environmental noise is not severe.

The receiver threshold level is established by applying a dc reference voltage to one receiver input terminal. The signal from the transmission line is applied to the remaining input. The reference voltage should be optimized so that signal swing is symmetrical about it for maximum noise margin. The reference voltage should be in the range of -3 volts to 3 volts. It can be provided by a voltage supply or by a voltage divider from an available supply voltage.

A single-ended output from a driver may be used in single-line systems. Coaxial or shielded line is preferred for minimum noise and crosstalk problems. For large signal swings, the high output current (typically 27 mA) of the SN75112 is recommended. Drivers may be paralleled for higher current. When using only one channel of the line drivers, the other channel should be inhibited and/or have its outputs grounded.

DUAL LINE RECEIVERS**

TYPICAL APPLICATION DATA

'108A, '108B dot-AND output connections

The '108A, '108B line receivers feature an open-collector-output circuit that can be connected in the dot-AND logic configuration with other similar open-collector outputs. This allows a level of logic to be implemented without additional logic delay.

FIGURE 13

increasing common-mode input voltage range of receiver

The common-mode voltage range or CMVR is defined as the range of voltage applied simultaneously to both input terminals that if exceeded does not allow normal operation of the receiver.

The recommended operating CMVR is ± 3 volts, making it useful in all but the noisiest environments. In extremely noisy environments, common-mode voltage can easily reach ± 10 V to ± 15 V if some precautions are not taken to reduce ground and power supply noise, as well as crosstalk problems. When the receiver must operate in such conditions, input attenuators should be used to decrease the system common-mode noise to a tolerable level at the receiver inputs. Differential noise is also reduced by the same ratio.

These attenuators have been intentionally omitted from the receiver input terminals so the designer may select resistors that will be compatible with his particular application or environment. Furthermore, the use of attenuators adversely affects the input sensitivity, the propagation delay time, the power dissipation, and in some cases (depending on the selected resistor values) the input impedance, therefore reducing the versatility of the receiver.

The ability of the receiver to operate with approximately ± 15 volts common-mode voltage at the inputs has been checked using the circuit shown in Figure 14. The resistors R1 and R2 provide a voltage divider network. Dividers with three different values presenting a 5-to-1 attenuation were used so as to operate the differential inputs at approximately ± 3 volts common-mode voltage. Careful matching of the two attenuators is needed so as to balance the overdrive at the input stage. The resistors used are shown in Table A.

TABLE A

Attenuator 1: R1 = 2 k Ω , R2 = 0.5 k Ω
Attenuator 2: R1 = 6 k Ω , R2 = 1.5 k Ω
Attenuator 3: R1 = 12 k Ω , R2 = 3 k Ω

Table B shows some of the typical switching results obtained under such conditions.

To minimize the loading, the values of R1 and R2 should be fairly large. Examples of possible values are shown in Table A.

furnace control using the SN75108A

The furnace control circuit in Figure 17 is an example of the possible use of the SN55107A Series in areas other than what would normally be considered electronic systems. Basically the operation of this control is as follows. When the room temperature is below the desired level, the resistance of the room temperature sensor is high and channel 1 noninverting input is below (less positive than) the reference level set on the input differential amplifier. This situation causes a low output, operating the "heat on" relay and turning on the heat. The channel 2 noninverting input is below the reference level when the bonnet temperature of the furnace reaches the desired level. This causes a low output, thus operating the blower relay. Normally the furnace is shut down when the room temperature reaches the desired level and the channel 1 output goes high, turning the heat off. The blower remains on as long as the bonnet temperature is high, even after the "heat on" relay is off. There is also a safety switch in the bonnet that shuts the furnace down if the temperature there exceeds desired limitations. The types of temperature-sensing devices and bias-resistor values used are determined by the particular operating conditions encountered.

repeaters for long lines

In some cases, the driven line may be so long that the noise level on the line reaches the common-mode limits or the attenuation becomes too large and results in poor reception. In such a case, a simple application of a receiver and a driver as repeaters [shown in Figure 18(a)] restores the signal level and allows an adequate signal level at the receiving end. If multichannel operation is desired, then proper gating for each channel must be sent through the repeater station using another repeater set as in Figure 18(b).

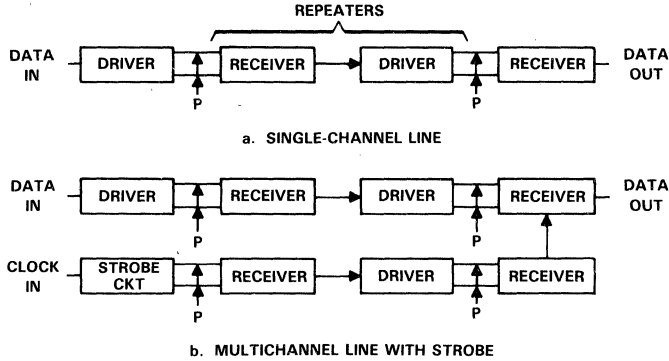

FIGURE 18. RECEIVER-DRIVER REPEATERS

receiver as dual differential comparator

There are many applications for differential comparators, such as voltage comparison, threshold detection, controlled Schmitt triggering, and pulse width control.

As a differential comparator, a '107A or '108A may be connected so as to compare the noninverting input terminal with the inverting input as shown in Figure 19. Thus the output will be high or low resulting from the A input being greater or less than the reference. The strobe inputs allow additional control over the circuit so that either output or both may be inhibited.

TYPICAL APPLICATION DATA

temperature controller with zero-voltage switching

The circuit in Figure 21 switches an electric resistive heater on or off by providing negative-going pulses to the gate of a triac during the time interval when the line voltage is passing through zero. The pulse generator is the 2N5447 and four diodes. This portion of the circuit provides negative-going pulses during the short time (approximately 100 μ s) when the line voltage is near zero. These pulses are fed to the inverting input of one channel of the '108A. If the room temperature is below the desired level, the resistance of the thermistor is high and the noninverting input of channel 2 is above the reference level determined by the thermostat setting. This provides a high-level output from channel 2. This output is AND'ed with the positive-going pulses from the output of channel 1, which are reinverted in the 2N5449. This output is AND'ed with the positive-going pulses from the output of channel 1, which are reinverted in the 2N5449.

SN55109A	SN75109A	6-mA Current Switch
SN55110A	SN75110A	12-mA Current Switch
	SN75112	27-mA Current Switch

description

The SN55109A, SN55110A, SN75109A, SN75110A, and SN75112 have improved output current regulation with supply voltage and temperature variations. In addition, the higher current of the SN75112 (27 mA) allows data to be transmitted over longer lines. These drivers offer optimum performance when used with the SN55107A, SN55108A, SN75107A, and SN75108A line receivers.

Line Drivers/Receivers

**SN55109A, SN55110A
SN75109A, SN75110A, SN75112
DUAL LINE DRIVERS**

description (continued)

These drivers feature independent channels with common voltage supply and ground terminals. The significant difference between the three drivers is in the output current specification. The driver circuits feature a constant output current that is switched to either of two output terminals by the appropriate logic levels at the input terminals. The output current can be switched off (inhibited) by low logic levels on the enable inputs. The output current is nominally 6 milliamperes for the '109A, 12 milliamperes for the '110A, and 27 milliamperes for the SN75112.

The enable/inhibit feature is provided so the circuits can be used in party-line or data-bus applications. A strobe or inhibitor (enable D), common to both drivers, is included for increased driver-logic versatility. The output current in the inhibited mode, $I_{O(off)}$, is specified so that minimum line loading is induced when the driver is used in a party-line system with other drivers. The output impedance of the driver in the inhibited mode is very high—the output impedance of a transistor biased to cutoff.

The driver outputs have a common-mode voltage range of -3 volts to 10 volts, allowing common-mode voltage on the line without affecting driver performance.

All inputs are diode clamped and are designed to satisfy TTL-system requirements. The inputs are tested at 2.0 volts for high-logic-level input conditions and 0.8 volt for low-logic-level input conditions. These test guarantee 400 millivolts of noise margin when interfaced with Series 54/74 TTL.

The SN55109A and SN55110A are characterized for operation over the full military temperature range of -55°C to 125°C. The SN75109A, SN75110A, and SN75112 are characterized for operation from 0°C to 70°C.

LOGIC INPUT	ENABLE INPUT	OUTPUT CURRENT	
		Z	Y
H	H	ON	OFF
L	H	OFF	ON
H	L	OFF	OFF
L	L	OFF	OFF

L = low logic level
H = high logic level

description

The SN75111 features four line drivers with a common enable input. When the enable input is high, a constant output current is switched between each pair of output terminals in response to the logic level at that channel's input. When the enable is low, all channel outputs are nonconductive (transistors biased to cutoff). This minimizes loading in party-line systems where a large number of drivers share the same line.

The driver outputs have a common-mode voltage range of -3 volts to 10 volts, allowing common-mode voltages on the line without affecting driver performance.

All inputs are diode clamped and are designed to satisfy TTL-system requirements. The inputs are tested at 2 volts for high-logic-level input conditions and 0.8 volt for low-logic-level input conditions. These tests guarantee 400 millivolts of noise margin when interfaced with Series 54/74 TTL.

The SN75111 is characterized for operation from 0°C to 70°C.

FIGURE 1. PROPAGATION DELAY TIMES

SN55113, SN75113 DUAL DIFFERENTIAL LINE DRIVERS

D1315, SEPTEMBER 1973—REVISED SEPTEMBER 1986

- Choice of Open-Collector, Open-Emitter, or 3-State Outputs
- High-Impedance Output State for Party-Line Applications
- Single-Ended or Differential AND/NAND Outputs
- Single 5-V Supply
- Dual Channel Operation
- Compatible with TTL
- Short-Circuit Protection
- High-Current Outputs
- Common and Individual Output Controls
- Clamp Diodes at Inputs and Outputs
- Easily Adaptable to SN55114 and SN75114 Applications
- Designed for Use with SN55115 and SN75115

description

The SN55113 and SN75113 dual differential line drivers with three-state outputs are designed to provide all the features of the SN55114 and SN75114 line drivers with the added feature of driver output controls. Individual controls are provided for each output pair, as well as a common control for both output pairs. If any output is low, the associated output is in a high-impedance state and the output can neither drive nor load the bus. This permits many devices to be connected together on the same transmission line for party-line applications.

The output stages are similar to TTL totem-pole outputs, but with the sink outputs, YS and ZS, and the corresponding active pull-up terminals, YP and ZP, available on adjacent package pins.

The SN55113 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75113 is characterized for operation over the temperature range of 0°C to 70°C .

- Designed for Use with SN55115 and SN75115 Differential Line Receivers
- Designed to be Interchangeable with Fairchild 9614 Line Driver

description

The SN55114 and SN75114 dual differential line drivers are designed to provide differential output signals with the high-current capability for driving balanced lines, such as twisted pair, at normal line impedances without high power dissipation. The output stages are similar to TTL totem-pole outputs, but with the sink outputs, YS and ZS, and the corresponding active pull-up terminals, YP and ZP, available on adjacent package pins. Since the output stages provide TTL-compatible output levels, these devices may also be used as TTL expanders or phase splitters.

The SN55114 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75114 is characterized for operation from 0°C to 70°C .

description

The SN55115 and SN75115 dual differential line receivers are designed to sense small differential signals in the presence of large common-mode noise. These devices give TTL-compatible output signals as a function of the differential input voltage. The open-collector output configuration permits the wire-ANDing of similar TTL outputs (such as SN5401/SN7401) or other SN55115/SN75115 line receivers. This permits a level of logic to be implemented without extra delay. The output stages are similar to TTL totem-pole outputs, but with sink outputs, 1YS and 2YS, and the corresponding active pull-up terminals, 1YP and 2YP, available on adjacent package pins. The frequency response and noise immunity may be provided by a single external capacitor. A strobe input is provided for each channel. With the strobe in the low level, the receiver is disabled and the outputs are forced to a high level.

The SN55115 is characterized for operation over the full military range of -55°C to 125°C . The SN75115 is characterized for operation from 0°C to 70°C .

description

These integrated circuits are designed for use in interfacing between TTL-type digital systems and differential data transmission lines. They are especially useful for party-line (data-bus) applications. Each of these circuit types combine in one package a three-state differential line driver and a differential-input line receiver, both of which operate from a single 5-volt power supply. The driver inputs and receiver outputs are TTL compatible. The driver employed is similar to the SN55113/SN75113 three-state line driver, and the receiver is similar to the SN55115/SN75115 line receiver.

The '116 and '118 circuits offer all the features of the SN55113/SN75113 driver and the SN55115/SN75115 receiver combined. The driver performs the dual input AND and NAND functions when enabled, or presents a high impedance to the load when in the disabled state. The driver output stages are similar to TTL totem-pole outputs, but have the current-sink portion separated from the current-sourcing portion and both are brought out to adjacent package pins. This feature allows the user the option of using the driver in the open-collector output configuration, or, by connecting the adjacent source and sink pins together, of using the driver in the normal totem-pole output configuration.

The receiver portion of the '116 and '118 features a differential-input circuit having a common-mode voltage range of ± 15 volts. An internal 130-ohm resistor is also provided, which may optionally be used for terminating the transmission line. A frequency response control pin allows the user to reduce the speed of the receiver or to improve differential noise immunity. The receiver of the '116 also has an output strobe and a split totem-pole output. The receiver of the '118 has an output-enable for the three-state split totem-pole output. The receiver section of either circuit is independent of the driver section except for the VCC and ground pins.

The '117 and '119 circuits provide the basic driver and receiver functions of the '116 and '118, but use a package that is only half as large. The '117 and '119 are intended primarily for party-line or bus-organized systems as the driver outputs are internally connected to the receiver inputs. The driver has a single data input and a single enable input, and the '117 receiver has an output strobe while the '119 receiver has a three-state-output enable. These devices do not, however, provide output connection options, line termination resistors, or receiver frequency-response controls.

The SN55116, SN55117, SN55118, and SN55119 are characterized for operation over the full military temperature range of -55°C to 125°C ; the SN75116, SN75117, SN75118, and SN75119 are characterized for operation from 0°C to 70°C .

† Unless otherwise noted V_{strobe} = 2.4 V. All parameters with the exception of off-state open-collector output current are measured with the active pull-up connected to the sink output. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions.

‡ All typical values are at V_{CC} = 5 V, T_A = 25°C, and V_{IC} = 0.

§ Differential voltages are at the B input terminal with respect to the A input terminal. Neither receiver input of the '117 or '119 should be taken negative with respect to GND.

¶ The algebraic convention, where the less positive (more negative) limit is designated as minimum, is used in this data sheet for threshold voltages only.

Input voltage range is the voltage range that, if exceeded at either input, will cause the receiver to cease functioning properly.

|| Not more than one output should be shorted at a time.

NOTES: 3. Measurement of these characteristics on the '117 and '119 requires the driver to be disabled with the driver enable at 0.8 V.

4. This applies with the less positive receiver input grounded.

5. For '116 and '118, this applies with the more positive receiver input at 15 V or the more negative receiver input at -15 V. For '117 and '119, this applies with the more positive receiver input at 6 V.

SN55121, SN75121 DUAL LINE DRIVERS

D1334, SEPTEMBER 1973—REVISED SEPTEMBER 1986

- Designed for Digital Data Transmission over 50-Ω to 500-Ω Coaxial Cable, Strip Line, or Twisted Pair
- High-Speed . . . $t_{pd} = 20$ ns Max at $C_L = 15$ pF
- TTL Compatible with Single 5-V Supply
- 2.4-V Output at $I_{OH} = -75$ mA
- Uncommitted Emitter-Follower Output Structure for Party-Line Operation
- Short-Circuit Protection
- AND-OR Logic Configuration
- Designed for Use with Triple Line Receivers SN55122, SN75122
- Designed to be Interchangeable with Signetics N8T13

description

The SN55121 and SN75121 dual line drivers are designed for digital data transmission over lines having impedances from 50 to 500 Ω. They are also compatible with standard TTL logic and supply voltage levels.

The low-impedance emitter-follower outputs of the SN55121 and SN75121 will drive terminated lines such as coaxial cable or twisted pairs. Having the outputs uncommitted allows wired-OR logic to be performed in party-line applications. Output short-circuit protection is provided by an internal clamping network that turns on when the output voltage drops below approximately 1.5 volts. All of the inputs are in conventional TTL configuration and the gating can be used during power-up and power-down sequences to ensure that no noise is introduced to the line.

The SN55121 is characterized for operation over the full military temperature range of -55°C to 125°C. The SN75121 is characterized for operation from 0°C to 70°C.

D1334, SEPTEMBER 1973—REVISED SEPTEMBER 1986

- Designed for Digital Data Transmission Over Coaxial Cable, Strip Line, or Twisted Pair
- Designed for Operation with 50-Ω to 500-Ω Transmission Lines
- TTL Compatible
- Single 5-V Supply
- Built-In Input Threshold Hysteresis
- High Speed . . . Typical Propagation Delay Time = 20 ns
- Independent Channel Strobes
- Input Gating Increases Application Flexibility
- Fanout to 10 Series 54/74 Standard Loads
- Can be Used with Dual Line-Drivers SN55121 and SN75121
- Interchangeable with Signetics N8T14

description

The SN55122 and SN75122 are triple line-receivers that are designed for digital data transmission over lines having impedances from 50 to 500 ohms. They are also compatible with standard TTL logic and supply voltage levels.

The SN55122 and SN75122 have receiver inputs with built-in hysteresis to provide increased noise margin for single-ended systems. The high impedance of this input presents a minimum load to the driver and allows termination of the transmission line in its characteristic impedance to minimize line reflection. An open line will affect the receiver input as would a low-level voltage. The receiver can withstand a level of -0.15 volt with power on or off. The other inputs are in TTL configuration. The S input must be high to enable the receiver input. Two of the line receivers have A and B inputs that, if both are high, will hold the output low. The third receiver has only an A input that, if high, will hold the output low.

The SN55122 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75122 is characterized for operation from 0°C to 70°C .

SN75123 DUAL LINE DRIVER

D1322, SEPTEMBER 1973—REVISED SEPTEMBER 1986

- Meets IBM System 360 Input/Output Interface Specifications
- Operates from Single 5-V Supply
- TTL Compatible
- 3.11 V Output at $I_{OH} = -59.3 \text{ mA}$
- Uncommitted Emitter-Follower Output Structure for Party-Line Operation
- Short-Circuit Protection
- AND-OR Logic Configuration
- Designed for Use with Triple Line Receiver SN75124
- Designed to be Interchangeable with Signetics N8T23

description

The SN75123 dual line driver is specifically designed to meet the input/output interface specifications for IBM System 360. It is also compatible with standard TTL logic and supply voltage levels.

The low-impedance emitter-follower outputs of the SN75123 will drive terminated lines such as coaxial cable or twisted pair. Having the outputs uncommitted allows wired-OR logic to be performed in party-line applications. Output short-circuit protection is provided by an internal clamping network that turns on when the output voltage drops below approximately 1.5 volts. All the inputs are in conventional TTL configuration and the gating can be used during power-up and power-down sequences to ensure that no noise is introduced to the line.

The SN75123 is characterized for operation from 0°C to 70°C.

description

The SN75125 and SN75127 are monolithic seven-channel line receivers designed to satisfy the requirements of the IBM System 360/370 input/output interface specifications. Special low-power design and Schottky-clamped transistors allow for low supply-current requirements while maintaining fast switching speeds and high-current TTL outputs.

The SN75125 and SN75127 are characterized for operation from 0°C to 70°C.

*S and \bar{S} for SN75128 and SN75129, respectively

description

The SN75128 and SN75129 are eight-channel line receivers designed to satisfy the requirements of the input-output interface specification for IBM 360/370. Both devices feature common strobes for each group of four devices. The SN75128 has active-high strobes; the SN75129 has active-low strobes. Special low-power design and Schottky-diode-clamped transistors allow low supply-current requirements while maintaining fast switching speeds and high-current TTL outputs.

The SN75128 and SN75129 are characterized for operation from 0°C to 70°C.

logic symbols†

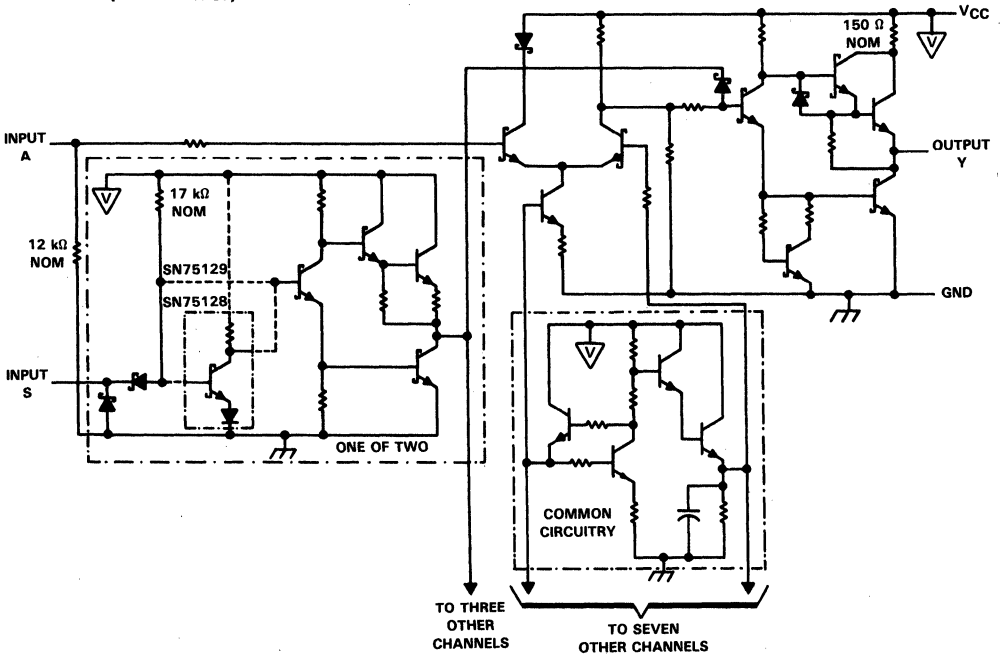

† These symbols are in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

SN75136 QUADRUPLE BUS TRANSCEIVER WITH 3-STATE OUTPUTS

D2291, JANUARY 1977—REVISED SEPTEMBER 1986

- P-N-P Inputs for Minimal Input Loading (200 μ A Maximum)
- High-Speed Schottky Circuitry
- 3-State Outputs for Driver and Receiver
- Party-Line (Data-Bus) Operation
- Single 5-V Supply
- Driver has 40-mA Current Sink Capability
- Designed to be Functionally Interchangeable with Signetics N8T26, also Called 8T26

D, J, OR N PACKAGE
(TOP VIEW)

description

The SN75136 is a quadruple transceiver utilizing Schottky-diode-clamped transistors. Both the driver and receiver have three-state outputs. With p-n-p inputs, the input loading is reduced to a maximum input current of 200 microamperes.

The SN75136 is characterized for operation from 0°C to 70°C.

Line Drivers/Receivers

SN55138, SN75138 QUADRUPLE BUS TRANSCEIVERS

D1663, SEPTEMBER 1973—REVISED SEPTEMBER 1986

- Single 5-V Supply
- High-Input-Impedance, High-Threshold Receivers
- Common Driver Strobe
- TTL-Compatible Driver and Strobe Inputs with Clamp Diodes
- High-Speed Operation
- 100-mA Open-Collector Driver Outputs
- Four Independent Channels
- TTL-Compatible Receiver Output

description

The SN55138 and SN75138 quad bus transceivers are designed for two-way data communication over single-ended transmission lines. Each of the four identical channels consists of a driver with TTL inputs and a receiver with a TTL output. The driver output is of the open-collector type, and is designed to handle loads of up to 100 milliamperes (50 ohms to 5 volts). The receiver input is internally connected to the driver output, and has a high impedance to minimize loading of the transmission line. Because of the high driver-output current and the high receiver-input impedance, a very large number (typically hundreds) of transceivers may be connected to a single data bus.

The receiver design also features a threshold of 2.3 volts (typical), providing a wider noise margin than would be possible with a receiver having the usual TTL threshold. A strobe turns off all drivers (high impedance) but does not affect receiver operation. These circuits are designed for operation from a single five-volt supply and include a provision to minimize loading of the data bus when the power-supply voltage is zero.

The SN55138 is characterized for operation over the full military temperature range of -55°C to 125°C ; the SN75138 is characterized for operation from 0°C to 70°C .

SN75140, SN75141 DUAL LINE RECEIVERS

D2155, JANUARY 1977—REVISED OCTOBER 1986

D, JG, OR P PACKAGE
(TOP VIEW)

- Single 5-V Supply
- ± 100 mV Sensitivity
- For Application As:
Single-Ended Line Receiver
Gated Oscillator
Level Comparator
- Adjustable Reference Voltage
- TTL Outputs
- TTL-Compatible Strobe
- Designed for Party-Line (Data-Bus) Applications
- Common Reference Pin
- Common Strobe
- '141 Has Diode-Protected Input Stage for Power-Off Condition

description

Each of these devices consists of a dual single-ended line receiver with TTL-compatible strobes and outputs. The reference voltage (switching threshold) is applied externally and can be adjusted from 1.5 volts to 3.5 volts, making it possible to optimize noise immunity for a given system design. Due to their low input current (less than 100 microamperes), they are ideally suited for party-line (bus-organized) systems.

The '140 has a common reference voltage pin and a common strobe. The '141 is the same as the '140 except that the input stage is diode protected.

The SN75140 and SN75141 are characterized for operation from 0°C to 70°C.

logic symbol†

† This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

FIGURE 2

TYPICAL APPLICATION DATA

line receiver

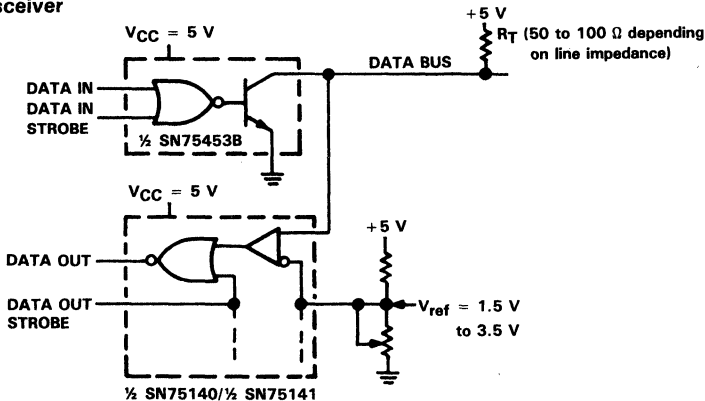

high fan-out from standard TTL gate

†Although most Series 54/74 circuits have a guaranteed 2.4-V output at 400 μ A, they are typically capable of maintaining a 2.4-V output level under a load of 7.5 mA.

dual bus transceiver

Using this arrangement, as many as 100 transceivers can be connected to a single data bus. The adjustable reference voltage feature allows the noise margin to be optimized for a given system. The complete dual bus transceiver (SN75453B driver and SN75140 receiver) can be assembled in approximately the same space required by a single 16-pin package and only one power supply is required (+5 V). Data In and Data Out terminals are TTL compatible.

SN75146 DUAL DIFFERENTIAL LINE RECEIVER

D2609, FEBRUARY 1986

- Meets EIA Standards RS-422-A and RS-423-A
- Meets EIA Standards RS-232 and CCITT V.28 with External Components
- Meets Federal Standards 1020 and 1030
- Built-in 5-MHz Low-Pass Filter
- Operates from Single 5-V Power Supply
- Wide Common-Mode Voltage Range
- High Input Impedance
- TTL-Compatible Outputs
- 8-Pin Dual-In-Line Package
- Pinout Compatible with the μ A9637 and μ A9639

logic symbol†

† This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

description

The SN75146 is a dual differential line receiver designed to meet EIA standards RS-422-A and RS-423-A. The receiver is designed to have a constant impedance with input voltages of ± 3 volts to ± 25 volts allowing it to meet the requirements of EIA standard RS-232-C and CCITT recommendation V.28 with the addition of an external bias resistor. This receiver is designed for low-speed operation below 355 kilohertz, and has a built-in 5-megahertz low-pass filter to attenuate high-frequency noise. The inputs are compatible with either a single-ended or a differential line system and the outputs are TTL compatible. This device operates from a single 5-volt power supply and is supplied in both the 8-pin dual-in-line and small outline packages.

The SN75146 is characterized for operation from 0°C to 70°C.

Line Drivers/Receivers

SN55150, SN75150 DUAL LINE DRIVERS

D951, JANUARY 1971—REVISED SEPTEMBER 1986

- Satisfies Requirements of EIA Standard RS-232-C
- Withstands Sustained Output Short-Circuit to any Low-Impedance Voltage Between -25 V and 25 V
- $2\ \mu\text{s}$ Max Transition Time Through the $+3\text{ V}$ to -3 V Transition Region Under Full 2500-pF Load
- Inputs Compatible with Most TTL Families
- Common Strobe Input
- Inverting Output
- Slew Rate can be Controlled with an External Capacitor at the Output
- Standard Supply Voltages . . . $\pm 12\text{ V}$

description

The SN55150 and SN75150 are monolithic dual line drivers designed to satisfy the requirements of the standard interface between data terminal equipment and data communication equipment as defined by EIA Standard RS-232-C. A rate of 20,000 bits per second can be transmitted with a full 2500-pF load. Other applications are in data-transmission systems using relatively short single lines, in level translators, and for driving MOS devices. The logic input is compatible with most TTL families. Operation is from $+12\text{-volt}$ and -12-volt power supplies.

The SN55150 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75150 is characterized for operation from 0°C to 70°C .

TYPICAL APPLICATION DATA

SN75151, SN75153 QUAD DIFFERENTIAL LINE DRIVERS WITH 3-STATE OUTPUTS

D2453, DECEMBER 1978—REVISED OCTOBER 1986

- Meets EIA Standard RS-422-A
- High-Impedance Output State for Party-Line Operation
- High Output Impedance in Power-Off Condition
- Low Input Current to Minimize Loading
- Single 5-V Supply
- 40-mA Sink- and Source-Current Capability
- High-Speed Schottky Circuitry
- Low Power Requirements

description

These line drivers are designed to provide differential signals with high current capability on balanced lines. These circuits provide strobe and enable inputs to control all four drivers, and the SN75151 provides an additional enable input for each driver. The output circuits have active pull-up and pull-down and are capable of sinking or sourcing 40 milliamperes.

The SN75151 and SN75153 meet all requirements of EIA Standard RS-422-A and Federal Standard 1020. They are characterized for operation from 0°C to 70°C.

			Outputs enabled	60		80	

† For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions.

‡ All typical values are at $T_A = 25^\circ\text{C}$ and $V_{CC} = 5 \text{ V}$ except for V_{OC} , for which V_{CC} is as stated under test conditions.

§ $\Delta|V_{OD}|$ and $\Delta|V_{OC}|$ are the changes in magnitudes of V_{OD} and V_{OC} , respectively, that occur when the input is changed from a high level to a low level.

¶ In EIA Standard RS-422-A, V_{OC} , which is the average of the two output voltages with respect to ground, is called output offset voltage, V_{OS} .

Only one output should be shorted at a time, and duration of the short-circuit should not exceed one second.

Line Drivers/Receivers

SN55152, SN75152 DUAL LINE RECEIVERS

D1114, AUGUST 1972—REVISED SEPTEMBER 1986

- Meets Specifications of EIA RS-232-C or MIL-STD-188C†
- Dual Differential Receiver with Independent Strobes
- Common-Mode Input Voltage Range . . . ± 25 V
- Differential Input Capability with One Input Grounded . . . ± 25 V
- Continuously Adjustable Hysteresis with External Resistors
- Standard Supply Voltages . . . +12 V and -12 V
- Input Hysteresis (Double Thresholds) Remain Approximately Fixed for Power Supply and/or Temperature Variations

description

The SN55152 and SN75152 are dual differential line receivers designed to meet the requirements of EIA Standard RS-232-C or MIL-STD-188 interfaces. A single control, HYST CONT, sets the input hysteresis for the required operation. An added feature is the capability of adjusting the hysteresis to any voltage between ± 0.3 volt typical and ± 5 volts typical by means of the hysteresis adjust terminals, 1HYST ADJ and 2HYST ADJ, making the SN55152 and SN75152 useful for a wide variety of line receiver and Schmitt trigger applications. The large common-mode input voltage range and differential input voltage (± 25 volts) give the circuit added versatility. The SN55152 and SN75152 are designed for operation from standard ± 12 -volt supplies with $\pm 10\%$ variation. Each receiver has an output strobe that is TTL compatible.

The SN55152 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75152 is characterized for operation from 0°C to 70°C .

† To meet the specifications of EIA Standard RS-232-C, connect the hysteresis control pin, HYST CONT, to V_{CC-} . Also, connect termination resistor pin $1R_T$ to inverting input $1IN-$, and termination resistor pin $2R_T$ to inverting input $2IN-$. To meet the specifications of MIL-STD-188, leave HYST CONT, $1R_T$, and $2R_T$ open.

**FUNCTION TABLE
(EACH RECEIVER)**

LINE INPUT	STROBE	OUTPUT
H	H	H
L	H	L
X	L	H

Definition of logic levels:

For the strobe: H (high) is any voltage between V_{IH} min and V_{CC} .

L (low) is any voltage between ground and V_{IL} max.

For the line input: H (high) is any differential input voltage (V_{ID})[‡] more positive than V_{T-} , once the level of V_{T+} has been reached.

L (low) is any differential input voltage (V_{ID})[‡] more negative than V_{T+} , once the level of V_{T-} has been reached.

X (irrelevant) is any input voltage permitted by maximum ratings.

[‡] Differential input voltages (V_T and V_{ID}) are at the noninverting input terminal $IN+$ with respect to the inverting input terminal $IN-$.

TYPICAL APPLICATIONS

Some typical applications of the SN55152 and SN75152 are as follows:

- MIL-STD-188 Interface Receiver
- EIA RS-232-C Interface Receiver
- Single-Ended Line Receiver
- Differential Line Receiver
- High-Noise-Immunity Line Receiver
- Schmitt Trigger
- High-Voltage-Logic-to-TTL Translator
- MOS-to-TTL Converter
- Pulse Generator
- Threshold Detector
- Pulse Shaper

NC: No internal connection
†For function of R1, see schematic

description

The SN55154 and SN75154 are monolithic Low-Power Schottky line receivers designed to satisfy the requirements of the standard interface between data terminal equipment and data communication equipment as defined by EIA standard RS-232-C. Other applications are for relatively short, single-line, point-to-point data transmission and for level translators. Operation is normally from a single five-volt supply; however, a built-in option allows operation from a 12-volt supply without the use of additional components. The output is compatible with most TTL circuits when either supply voltage is used.

In normal operation, the threshold-control terminals are connected to the VCC1 terminal, even if power is being supplied via the alternate VCC2 terminal. This provides a wide hysteresis loop, which is the difference between the positive-going and negative-going threshold voltages. See typical characteristics. In this mode of operation, if the input voltage goes to zero, the output voltage will remain at the low or high level as determined by the previous input.

For fail-safe operation, the threshold-control terminals are open. This reduces the hysteresis loop by causing the negative-going threshold voltage to be above zero. The positive-going threshold voltage remains above zero as it is unaffected by the disposition of the threshold terminals. In the fail-safe mode, if the input voltage goes to zero or an open-circuit condition, the output will go to the high level regardless of the previous input condition.

The SN55154 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75154 is characterized for operation from 0°C to 70°C .

logic diagram

description

The SN75155 is a monolithic line driver and receiver that is designed to satisfy the requirements of the standard interface between data terminal equipment and data communication equipment as defined by EIA standard RS-232-C. A Response Control input is provided for the receiver. A resistor or a resistor and a bias voltage can be connected between the response control input and ground to provide noise filtering. The driver used is similar to the SN75188. The receiver used is similar to the SN75189A.

The SN75155 is characterized for operation from 0°C to 70°C.

description

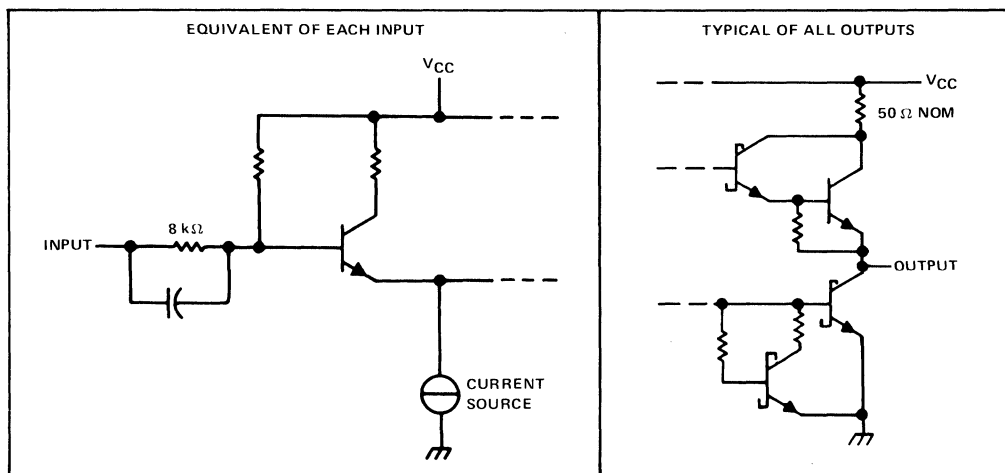

The SN75157 is a dual differential line receiver designed to meet EIA standards RS-422-A and RS-423-A and Federal Standards 1020 and 1030. It utilizes Schottky circuitry and has TTL-compatible outputs. The inputs are compatible with either a single-ended or a differential-line system. The device operates from a single 5-volt power supply and is supplied in an 8-pin dual-in-line package and small outline package.

The SN55157 is characterized over the full military temperature range of -55°C to 125°C . The SN75157 is characterized for operation from 0°C to 70°C .

description

The SN55158 and SN75158 are dual complementary-output line drivers designed to satisfy the requirements set by the EIA Standard RS-422-A interface specifications. The outputs provide complementary signals with high-current capability for driving balanced lines, such as twisted pair, at normal line impedance without high power dissipation. The output stages are TTL totem-pole outputs providing a high-impedance state in the power-off condition.

The SN55158 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75158 is characterized for operation from 0°C to 70°C .

Δ V _{OD}	Change in magnitude of differential output voltage§	V _{CC} = MIN			±0.02	±0.4	±0.02	±0.4	V		
V _{OC}	Common-mode output voltage¶	V _{CC} = MAX			1.9	3	1.8	3	V		
		V _{CC} = MIN			1.4	3	1.5	3	V		
Δ V _{OC}	Change in magnitude of common-mode output voltage§	V _{CC} = MIN or MAX			±0.01	±0.4	±0.01	±0.4	V		
I _O	Output current with power off	V _{CC} = 0			V _O = 6 V			0.1	100	μA	
					V _O = -0.25 V			-0.1	-100		
					V _O = -0.25 to 6 V			±100	±100		
I _I	Input current at maximum input voltage	V _{CC} = MAX, V _I = 5.5 V						1	1	mA	
I _{IH}	High-level input current	V _{CC} = MAX, V _I = 2.4 V						40	40	μA	
I _{IL}	Low-level input current	V _{CC} = MAX, V _I = 0.4 V						-1	-1.6	mA	
I _{OS}	Short-circuit output current#	V _{CC} = MAX			-40	-90	-150	-40	-90	-150	mA
I _{CC}	Supply current (both drivers)	V _{CC} = MAX, Inputs grounded, No load, T _A = 25°C			37	50	37	50	mA		

† For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions.

‡ All typical values are at V_{CC} = 5 V and T_A = 25°C except for V_{OC}, for which V_{CC} is as stated under test conditions.

§ Δ|V_{OD}| and Δ|V_{OC}| are the changes in magnitudes of V_{OD} and V_{OC}, respectively, that occur when the input is changed from a high level to a low level.

¶ In EIA Standard RS-422-A, V_{OC}, which is the average of the two output voltages with respect to ground, is called output offset voltage, V_{OS}.

Only one output should be shorted at a time, and duration of the short-circuit should not exceed one second.

NC—No internal connection

description

The SN75159 dual differential line driver with three-state outputs is designed to provide all the features of the SN75158 line driver with the added feature of driver output controls. There is an individual control for each driver. When the output control is low, the associated outputs are in a high-impedance state and the outputs can neither drive nor load the bus. This permits many devices to be connected together on the same transmission line for party-line applications.

The SN75159 is characterized for operation from 0°C to 70°C.

logic symbol†

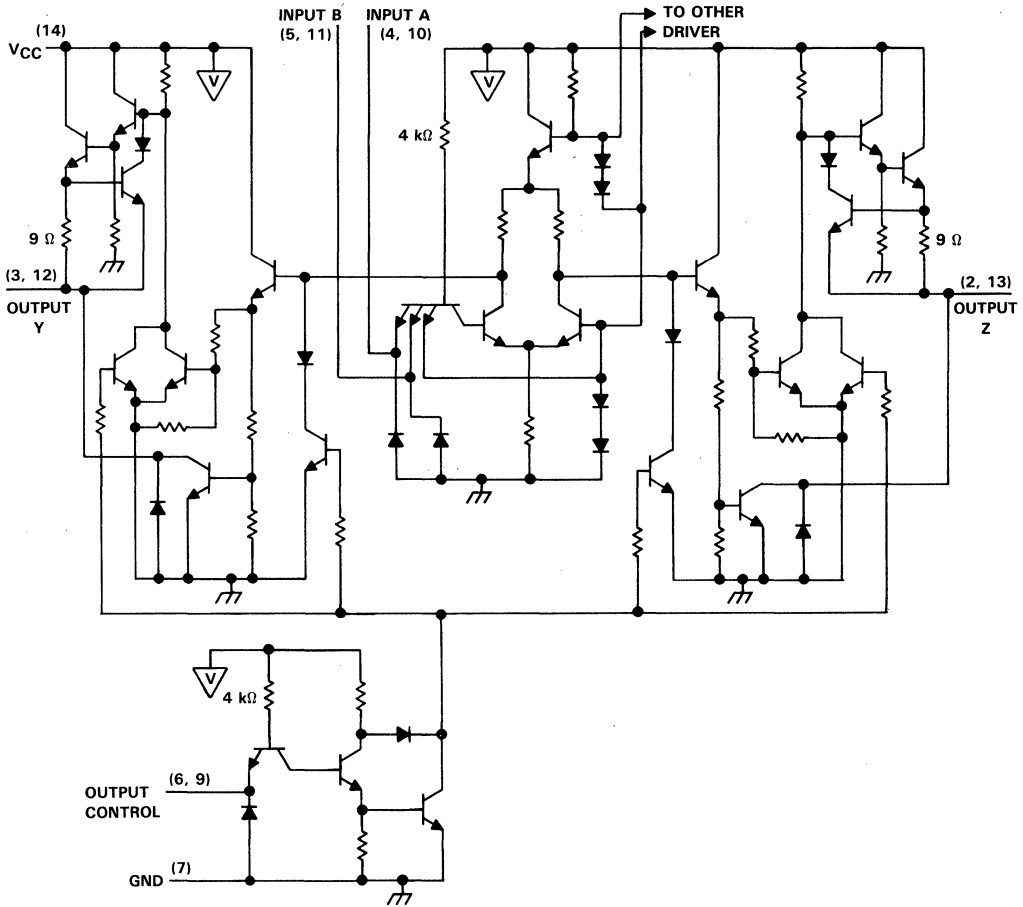

† This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

description

The SN75160B 8-channel general-purpose interface bus transceiver is a monolithic, high-speed, low-power Schottky device designed for two-way data communications over single-ended transmission lines. It is designed to meet the requirements of IEEE Standard 488-1978. The transceiver features driver outputs that can be operated in either the passive-pullup or three-state mode. If Talk Enable (TE) is high, these ports have the characteristics of passive-pullup outputs when Pullup Enable (PE) is low, and of three-state outputs when PE is high. Taking TE low places these ports in the high-impedance state. The driver outputs are designed to handle loads up to 48 milliamperes of sink current.

Output glitches during power-up and power-down are eliminated by an internal circuit that disables both the bus and receiver outputs. The outputs do not load the bus when $V_{CC} = 0$ volts. When combined with the SN75161B or SN75162B management bus transceivers, the pair provides the complete 16-wire interface for the IEEE 488 bus.

The SN75160B is characterized for operation from 0°C to 70°C.

description

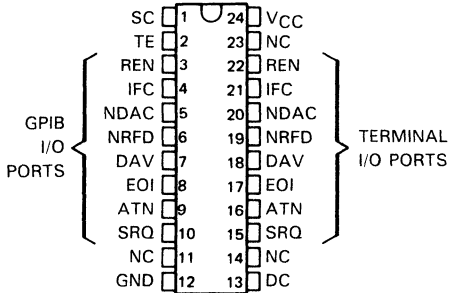

The SN75161B and SN75162B eight-channel general-purpose interface bus transceivers are monolithic, high-speed, low-power Schottky devices designed to meet the requirements of IEEE Standard 488-1978. Each transceiver is designed to provide the bus-management and data-transfer signals between operating units of a single- or multiple-controller instrumentation system. When combined with the SN75160B octal bus transceiver, the SN75161B or SN75162B provides the complete 16-wire interface for the IEEE 488 bus.

The SN75161B and SN75162B each features eight driver-receiver pairs connected in a front-to-back configuration to form input/output (I/O) ports at both the bus and terminal sides. A power up/down disable circuit is included on all bus and receiver outputs. This provides glitch-free operation during V_{CC} power-up and power-down. The direction of data through these driver-receiver pairs is determined by the DC, TE, and SC (on SN75162B) enable signals. The SC input on the SN75162B allows the REN and IFC transceivers to be controlled independently.

SN75161B, SN75162B OCTAL GENERAL-PURPOSE INTERFACE BUS TRANSCEIVERS

The driver outputs (GPIB I/O ports) feature active bus-terminating resistor circuits designed to provide a high impedance to the bus when supply voltage V_{CC} is 0. The drivers are designed to handle loads up to 48 milliamperes of sink current. Each receiver features p-n-p transistor inputs for high input impedance and a guaranteed hysteresis of 400 millivolts for increased noise immunity. All receivers have 3-state outputs to present a high impedance to the terminal when disabled.

The SN75161B and SN75162B are characterized for operation from 0°C to 70°C.

FUNCTION TABLES

description

The SN75163B octal general-purpose interface bus transceiver is a monolithic, high-speed, low-power Schottky device. It is designed for two-way data communications over single-ended transmission lines. The transceiver features driver outputs that can be operated in either the open-collector or three-state modes. If Talk Enable (TE) is high, these outputs have the characteristics of open-collector outputs when Pullup Enable (PE) is low and of three-state outputs when PE is high. Taking TE low places the outputs in the high-impedance state. The driver outputs are designed to handle loads of up to 48 milliamperes of sink current. Each receiver features p-n-p transistor inputs for high input impedance and 400 millivolts of guaranteed hysteresis for increased noise immunity.

Output glitches during power-up and power-down are eliminated by an internal circuit that disables both the bus and receiver outputs. The outputs do not load the bus when $V_{CC} = 0$ volts.

The SN75163B is characterized for operation from 0°C to 70°C.

EACH DRIVER			
INPUTS			OUTPUT
D	TE	PE	B
H	H	H	H
L	H	H	L
H	X	L	Z
L	H	L	L
X	L	X	Z

EACH RECEIVER			
INPUTS			OUTPUT
B	TE	PE	D
L	L	X	L
H	L	X	H
X	H	X	Z

H = high level, L = low level, X = irrelevant, Z = high-impedance state.

description

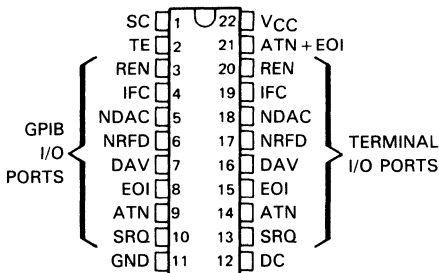

The SN75164B eight-channel general-purpose interface bus transceiver is a monolithic, high-speed, low-power Schottky device designed to meet the requirements of IEEE Standard 488-1978. Each transceiver is designed to provide the bus-management and data-transfer signals between operating units of a multiple-controller instrumentation system. When combined with the SN75160B octal bus transceiver, the SN75164B provides the complete 16-wire interface for the IEEE 488 bus.

The SN75164B features eight driver-receiver pairs connected in a front-to-back configuration to form input/output (I/O) ports at both the bus and terminal sides. All outputs are disabled (at a high-impedance state) during V_{CC} power-up and power-down transitions for glitch-free operation. The direction of data flow through these driver-receiver pairs is determined by the DC, TE, and SC enable signals. The SN75164B is identical to the SN75162B with the addition of an OR gate to help simplify board layouts in several popular applications. The ATN and EOI signals are ORed to pin 21, which is a standard totem-pole output.

Line Drivers/Receivers

SN75164B OCTAL GENERAL-PURPOSE INTERFACE BUS TRANSCEIVER

The driver outputs (GPIO I/O ports) feature active bus-terminating resistor circuits designed to provide a high impedance to the bus when supply voltage V_{CC} is 0. The drivers are designed to handle loads up to 48 milliamperes of sink current. Each receiver features p-n-p transistor inputs for high input impedance and a guaranteed hysteresis of 400 millivolts for increased noise immunity. All receivers have 3-state outputs to present a high impedance to the terminal when disabled.

The SN75164B is manufactured in a 22-pin dual-in-line and 24-pin Small Outline package. The SN75164B is characterized for operation from 0°C to 70°C.

SN75172 QUADRUPLE DIFFERENTIAL LINE DRIVER

D2596, OCTOBER 1980—REVISED SEPTEMBER 1986

- Meets EIA Standards RS-422-A and RS-485
- Meets CCITT Recommendations V.11 and X.27
- Designed for Multipoint Transmission on Long Bus Lines in Noisy Environments
- 3-State Outputs
- Common-Mode Output Voltage Range of -7 V to 12 V
- Active-High and Active-Low Enables
- Thermal Shutdown Protection
- Positive- and Negative-Current Limiting
- Operates from Single 5-V Supply
- Low Power Requirements
- Functionally Interchangeable with AM26LS31

J OR N DUAL-IN-LINE PACKAGE
(TOP VIEW)

description

The SN75172 is a monolithic quadruple differential line driver with three-state outputs. It is designed to meet the requirements of EIA Standards RS-422-A and RS-485 and CCITT Recommendations V.11 and X.27. The device is optimized for balanced multipoint bus transmission at rates of up to 4 megabaud. Each driver features wide positive and negative common-mode output voltage ranges making it suitable for party-line applications in noisy environments.

The SN75172 provides positive- and negative-current limiting and thermal shutdown for protection from line fault conditions on the transmission bus line. Shutdown occurs at a junction temperature of approximately 150°C. This device offers optimum performance when used with the SN75173 or SN75175 quadruple differential line receivers.

The SN75172 is characterized for operation from 0°C to 70°C.

description

The SN75173 is a monolithic quadruple differential line receiver with three-state outputs. It is designed to meet the requirements of EIA Standards RS-422-A, RS-423-A, and RS-485 and several CCITT recommendations. The device is optimized for balanced multipoint bus transmission at rates up to 10 megabits per second. Each of the two pairs of receivers has a common active-high enable. The device features high input impedance, input hysteresis for increased noise immunity, and input sensitivity of ± 200 millivolts over a common-mode input voltage range of -12 to 12 volts. The SN75173 is designed for optimum performance when used with the SN75172 or SN75174 quadruple differential line drivers.

The SN75173 is characterized for operation from 0°C to 70°C.

SN75175 QUADRUPLE DIFFERENTIAL LINE RECEIVER

D2602, OCTOBER 1980—REVISED SEPTEMBER 1986

- Meets EIA Standards RS-422-A, RS-423-A, and RS-485
- Meets CCITT Recommendations V.10, V.11, X.26, and X.27
- Designed for Multipoint Bus Transmission on Long Bus Lines in Noisy Environments
- 3-State Outputs
- Common-Mode Input Voltage Range -12 V to 12 V
- Input Sensitivity . . . ±200 mV
- Input Hysteresis . . . 50 mV Typ
- High Input Impedance . . . 12 kΩ Min
- Operates from Single 5-Volt Supply
- Low Power Requirements
- Plug-in Replacement for MC3486

description

The SN75175 is a monolithic quadruple differential line receiver with three-state outputs. It is designed to meet the requirements of EIA Standards RS-422-A, RS-423-A, and RS-485 and several CCITT recommendations. The device is optimized for balanced multipoint bus transmission at rates up to 10 megabits per second. Each of the two pairs of receivers has a common active-high enable.

The receivers feature high input impedance, input hysteresis for increased noise immunity, and input sensitivity of ±200 millivolts over a common-mode input voltage range of ±12 volts. The SN75175 is designed for optimum performance when used with the SN75172 or SN75174 quadruple differential line drivers.

The SN75175 is characterized for operation from 0°C to 70°C.

FUNCTION TABLE (EACH RECEIVER)

description

The SN65176B and SN75176B differential bus transceivers are monolithic integrated circuits designed for bidirectional data communication on multipoint bus transmission lines. They are designed for balanced transmission lines and meet EIA Standard RS-422-A and RS-485 and CCITT Recommendations V.11 and X.27.

The SN65176B and SN75176B combine a three-state differential line driver and a differential input line receiver both of which operate from a single 5-volt power supply. The driver and receiver have active-high and active-low enables, respectively, that can be externally connected together to function as a direction control. The driver differential outputs and the receiver differential inputs are connected internally to form differential input/output (I/O) bus ports that are designed to offer minimum loading to the bus whenever the driver is disabled or $V_{CC} = 0$ volts. These ports feature wide positive and negative common-mode voltage ranges making the device suitable for party-line applications.

logic symbol†

†This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

logic diagram (positive logic)

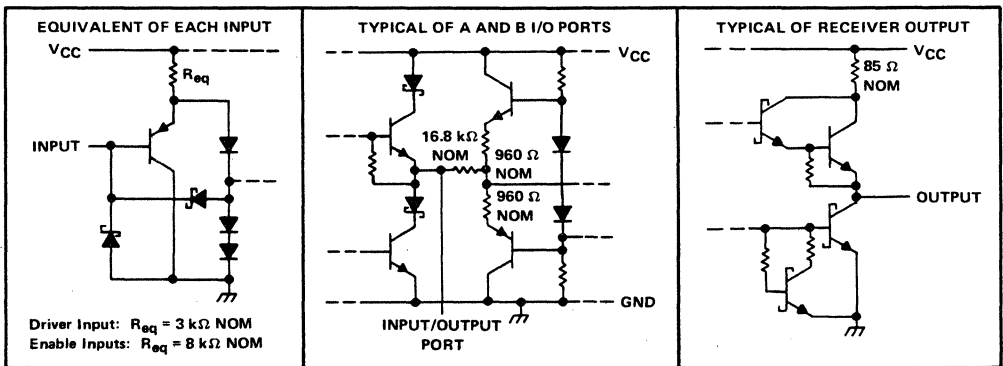

ADVANCE INFORMATION documents contain information on new product in the sampling or preproduction phase of development. Characteristic data and other specifications are subject to change without notice.

The driver is designed to handle loads up to 60 milliamperes of sink or source current. The driver features positive- and negative-current limiting and thermal shutdown for protection from line fault conditions. Thermal shutdown is designed to occur at a junction temperature of approximately 150°C. The receiver features a minimum input impedance of 12 kΩ, an input sensitivity of ±200 millivolts, and a typical input hysteresis of 50 millivolts.

The SN65176B and SN75176B can be used in transmission line applications employing the SN75172 and SN75174 quadruple differential line drivers and SN75173 and SN75175 quadruple differential line receivers.

The SN65176B is characterized for operation from -40°C to 85°C and the SN75176B is characterized for operation from 0°C to 70°C.

description

The SN75177B and SN75178B differential bus repeaters are monolithic integrated devices each designed for one-way data communication on multipoint bus transmission lines. These devices are designed for balanced transmission bus line applications and meet EIA Standards RS-422-A and RS-485 and CCITT Recommendations V.11 and X.27. Each device is designed to improve the performance of the data communication over long bus lines. The SN75177B and SN75178B are identical except for the complementary enable inputs, which allow the devices to be used in pairs for bidirectional communication.

The SN75177B and SN75178B feature positive- and negative-current limiting three-state outputs for the receiver and driver. The receiver features high input impedance, input hysteresis for increased noise immunity, and input sensitivity of ± 200 millivolts over a common-mode input voltage range of -7 volts to 12 volts. The driver features thermal shutdown for protection from line fault conditions. Thermal shutdown is designed to occur at a junction temperature of approximately 150°C. The driver is designed to drive current loads up to 60 milliamperes maximum.

The SN75177B and SN75178B are designed for optimum performance when used on transmission buses employing the SN75172 and SN75174 differential line drivers, SN75173 and SN75175 differential line receivers, or SN75176B bus transceivers.

description

The SN75179B driver and bus receiver circuit is a monolithic integrated device designed for balanced transmission line applications and meets EIA Standards RS-422-A and RS-485 and CCITT Recommendations V.11 and X.27. It is designed to improve the performance of full-duplex data communications over long bus lines.

The SN75179B driver outputs provide limiting for both positive and negative currents. The receiver features high input impedance, input hysteresis for increased noise immunity, and input sensitivity of ± 200 millivolts over a common-mode input voltage range of -12 volts to 12 volts. The driver provides thermal shutdown for protection from line fault conditions. Thermal shutdown is designed to occur at a junction temperature of approximately 150°C. The device is designed to drive current loads of up to 60 milliamperes maximum.

The SN75179B is characterized for operation from 0°C to 70°C.

SN55182, SN75182 DUAL DIFFERENTIAL LINE RECEIVERS

D1292, OCTOBER 1972—REVISED SEPTEMBER 1986

- Single 5-V Supply
- Differential Line Operation
- Dual Channels
- TTL Compatibility
- ± 15 V Common-Mode Input Voltage Range
- ± 15 V Differential Input Voltage Range
- Individual Channel Strobes
- Built-In Optional Line-Termination Resistor
- Individual Frequency Response Controls
- Designed for Use with Dual Differential Drivers SN55183 and SN75183
- Designed to be Interchangeable with National Semiconductor DS7820A and DS8820A

description

The SN55182 and SN75182 dual differential line receivers are designed to sense small differential signals in the presence of large common-mode noise. These devices give TTL-compatible output signals as a function of the polarity of the differential input voltage. The frequency response of each channel may be easily controlled by a single external capacitor to provide immunity to differential noise spikes. The output goes to a high level when the inputs are open-circuited. A strobe input is provided which, when in the low level, disables the receiver and forces the output to a high level.

The receiver is of monolithic single-chip construction, and both halves of the dual circuits use common power supply and ground terminals.

The SN55182 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75182 is characterized for operation from 0°C to 70°C .

TYPICAL APPLICATION DATA

4

Line Drivers/Receivers

NOTES: A. When the inputs are open-circuited, the output will be high. A capacitor may be used for dc isolation of the line-terminating resistor. At the frequency of operation, the impedance of the capacitor should be relatively small.

Example: let $f = 5 \text{ MHz}$
 $C = 0.002 \mu\text{F}$

$$Z_C = \frac{1}{2\pi fC} = \frac{1}{2\pi (5 \times 10^6) (0.002 \times 10^{-6})}$$

$$Z_C \approx 16 \Omega$$

B. Use of a capacitor to control response time is optional.

SN55183, SN75183 DUAL DIFFERENTIAL LINE DRIVERS

D1292, OCTOBER 1972—REVISED SEPTEMBER 1986

- Single 5-V Supply
- Differential Line Operation
- Dual Channels
- TTL Compatibility
- Short-Circuit Protection of Outputs
- Output Clamp Diodes to Terminate Line Transients
- High-Current Outputs
- Quad Inputs
- Single-Ended or Differential AND/NAND Outputs
- Designed for Use with Dual Differential Drivers SN55182 and SN75182
- Designed to be Interchangeable with National Semiconductor DS7830 and DS8830

description

The SN55183 and SN75183 dual differential line drivers are designed to provide differential output signals with high-current capability for driving balanced lines, such as twisted-pair, at normal line impedances without high power dissipation. These devices may be used as TTL expander/phase splitters, as the output stages are similar to TTL totem-pole outputs.

The driver is of monolithic single-chip construction, and both halves of the dual circuits use common power supply and ground terminals.

The SN55183 is characterized for operation over the full military temperature range of -55°C to 125°C . The SN75183 is characterized for operation from 0°C to 70°C .

description

These devices are monolithic Low-power Schottky quadruple line receivers designed to satisfy the requirements of the standard interface between data terminal equipment and data communication equipment as defined by EIA Standard RS-232-C. A separate response control terminal is provided for each receiver. A resistor or a resistor and bias voltage source can be connected between this terminal and ground to shift the input threshold levels. An external capacitor can be connected between this terminal and ground to provide input noise filtering.

The SN55189 and SN55189A are characterized for operation over the full military temperature range of -55°C to 125°C . The SN75189 and SN75189A are characterized for operation from 0°C to 70°C .

description

The SN75207, SN75207B, SN75208, and SN75208B are pin-for-pin replacements for the SN75107A, SN75107B, SN75108A, and SN75108B, respectively. The improved input sensitivity makes them more suitable for MOS memory sense amplifiers and can result in faster memory cycles. Improved sensitivity also makes them more useful in line receiver applications by allowing use of longer transmission line lengths. The '207 and '207B each features a TTL-compatible active-pull-up output. The '208 and '208B each features an open-collector output that permits wired-AND logic connections with similar output configurations.

The essential difference between the unsuffixed and "B" versions can be seen in the schematics. Input-protection diodes are in series with the collectors of the differential-input transistors of the "B" versions. These diodes are useful in certain "party-line" systems that may have multiple V_{CC+} power supplies and may be operated with some of the V_{CC+} supplies turned off. In such a system, if a supply is turned off and allowed to go to ground, the equivalent input circuit connected to that supply would be as follows:

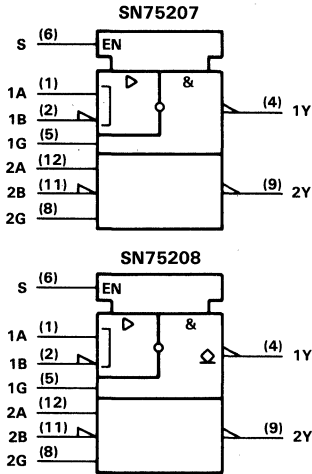

This would be a problem in specific systems that might possibly have the transmission lines biased to some potential greater than 1.4 volts.

These devices are characterized for operation from 0°C to 70°C and are available in ceramic dual-in-line (J) package, plastic small outline (D) package, or plastic dual-in-line (N) package.

SN75207, SN75207B, SN75208, SN75208B DUAL SENSE AMPLIFIERS FOR MOS MEMORIES OR DUAL HIGH-SENSITIVITY LINE RECEIVERS

design characteristics

The '207, '207B, '208, and '208B line receivers/sense amplifiers are TTL-compatible dual circuits intended for use in high-speed data-transmission systems or MOS memory systems. They are designed to detect low-level differential signals in the presence of common-mode noise and variations of temperature and supplies. Dc specifications reflect worst-case conditions of temperature, supply voltages, and input voltages.

The input common-mode voltage range is ± 3 volts. This is adequate for application in most systems. In systems with requirements for greater common-mode voltage range, input attenuators may be used to decrease the noise to an acceptable level at the receiver-input terminals.

The circuits feature individual strobe inputs for each channel and a strobe input common to both channels for logic versatility. The strobe inputs are tested to guarantee 400 millivolts of dc noise margin when interfaced with Series 54/74 TTL.

The circuits feature high input impedance and low input currents, which induce very little loading on the transmission line. This makes these devices especially useful in party-line systems. The excellent input sensitivity (3 millivolts typical) is particularly important when data is to be detected at the end of a long transmission line and the amplitude of the data has deteriorated due to cable losses. The circuits are designed to detect input signals of 10 millivolts (or greater) amplitude and convert the polarity of the signal into appropriate TTL-compatible output logic levels.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC+} (see Note 1)	7 V
Supply voltage, V_{CC-}	-7 V
Differential input voltage (see Note 2)	± 6 V
Common-mode input voltage (see Note 3)	± 5 V
Strobe input voltage	5.5 V
Continuous total dissipation at (or below) 25°C free-air temperature: (see Note 4)	
D package	950 mW
J package	1025 mW
N package	1150 mW
Operating free-air temperature range	0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds:	
J package	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds:	
D or N package	260°C

- NOTES: 1. All voltage values, except differential voltages, are with respect to ground terminal.
 2. Differential input voltage values are at the noninverting (A) terminal with respect to the inverting (B) terminal.
 3. Common-mode input voltage is the average of the voltages at the A and B inputs.
 4. For operation above 25°C free-air temperature, derate linearly to 608 mW at 70°C at the rate of 7.6 mW/°C for the D package, 656 mW at 70°C at the rate of 8.2 mW/°C for the J package, and 736 mW at 70°C at the rate of 9.2 mW/°C for the N package.

TYPICAL APPLICATION DATA

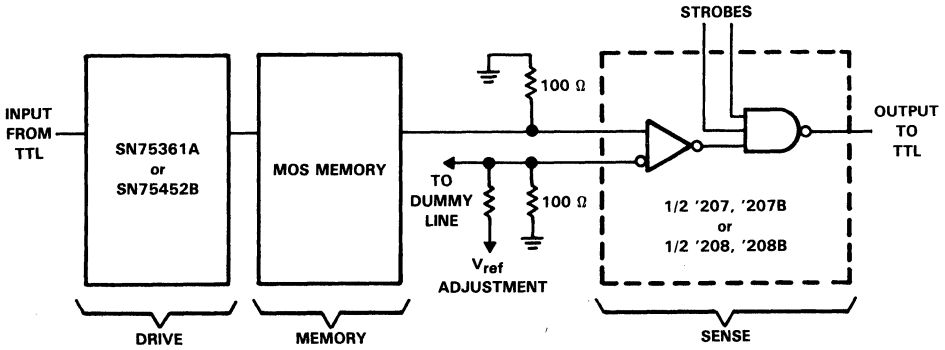

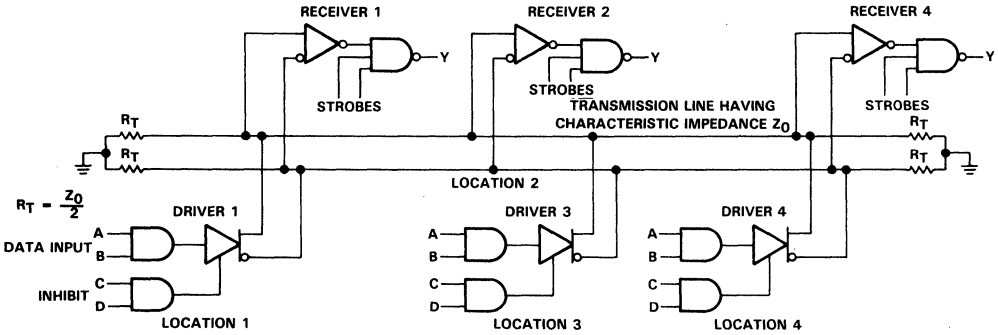

FIGURE 2. MOS MEMORY SENSE AMPLIFIER

Receivers are '207, '207B, or '208', or '208B; drivers are SN55109A, SN75109A, SN55110A, SN75110A, or SN75112.

FIGURE 3. DATA-BUS OR PARTY-LINE SYSTEM

PRECAUTIONS: When only one receiver in a package is being used, at least one of the differential inputs of the unused receiver should be terminated at some voltage between -3 volts and 3 volts, preferably at ground. Failure to do so will cause improper operation of the unit being used because of common bias circuitry for the current sources of the two receivers. Strobe G of the unused channel should be grounded.

description

The SN75ALS126 quadruple line driver is designed to meet the IBM360/370 I/O specifications GA22-6974-3. The output voltage is 3.11 volts minimum (at $I_{OH} = -59.3$ milliamperes) over the recommended ranges of supply voltage (4.5 volts to 5.5 volts) and temperature (0°C to 70°C). Driver outputs use a fault-detection current-limit circuit to allow high drive current but still minimize power dissipation when the output is shorted to ground. The SN75ALS126 is compatible with standard TTL logic and supply voltages.

The SN75ALS126 employs the IMPACT™ process to achieve fast switching speeds and low power dissipation. Fault-flag circuitry is designed to sense and signal a line short on any Y line. Upon detecting an output fault condition, the fault-flag circuit forces the driver output into a low state and signals a fault condition by causing the fault-flag output to go low.

The SN75ALS126 will drive a 50-ohm load as required in the IBM GA22-6974-3 specification or a 90-ohm load as used in many I/O systems. Optimum performance can be achieved when the device is used with either the SN75125, SN75127, SN75128, or SN75129 line receivers.

The SN75ALS126 is characterized for operation from 0°C to 70°C.

FUNCTION TABLE

INPUTS		OUTPUTS			
G [†]	A	Y	F [†]	W	
L	X	L	H	H	
X	L	L	H	H	
H	H	H	H	L	
H	H	S	L	H	

H = high level, L = low level,
X = irrelevant, S = shorted to ground

[†]G and F are common to the four drivers. If any of the four Y outputs is shorted, the Fault-Flag will respond.

description

The SN75ALS130 quadruple line driver is designed to meet the IBM 360/370 I/O specifications GA22-6974-3. The output voltage is 3.11 volts minimum (at $I_{OH} = -59.3$ milliamperes) over the recommended ranges of supply voltage (4.5 volts to 5.5 volts) and temperature (0°C to 70°C). Driver outputs use a fault-detection current limit circuit to allow high drive current but still minimize power dissipation when the output is shorted to ground. The SN75ALS130 is compatible with standard TTL logic and supply voltages.

The SN75ALS130 employs the IMPACT™ process to achieve fast switching speeds and low power dissipation. Fault-flag circuitry is designed to sense and signal a line short on any Y line. Upon detecting an output fault condition, the fault-flag circuit forces the driver output into the off (low) state and signals a fault condition by causing the fault-flag output to go low.

The SN75ALS130 will drive a 50-ohm load as required in the IBM GA22-6974-3 specification or a 90-ohm load as used in many I/O systems. Optimum performance can be achieved when the device is used with either the SN75125, SN75127, SN75128, or SN75129 line receivers.

The SN75ALS130 is characterized for operation from 0°C to 70°C.

description

The SN75ALS160 eight-channel general-purpose interface bus transceiver is a monolithic, high-speed, Advanced Low-Power Schottky device designed for two-way data communications over single-ended transmission lines. It is designed to meet the requirements of IEEE Standard 488-1978. The transceiver features driver outputs that can be operated in either the passive-pullup or three-state mode. If Talk Enable (TE) is high, these ports have the characteristics of passive-pullup outputs when Pullup Enable (PE) is low, and of three-state outputs when PE is high. Taking TE low places these ports in the high-impedance state. The driver outputs are designed to handle loads up to 48 milliamperes of sink current.

An active turn-off feature has been incorporated into the bus-terminating resistors so that the device exhibits a high impedance to the bus when $V_{CC} = 0$. When combined with the SN75ALS161 or SN75ALS162 management bus transceiver, the pair provides the complete 16-wire interface for the IEEE 488 bus.

The SN75ALS160 is manufactured in a 20-pin package and is characterized for operation from 0°C to 70°C.

FUNCTION TABLES

EACH DRIVER				EACH RECEIVER			
INPUTS			OUTPUT	INPUTS			OUTPUT
D	TE	PE	B	B	TE	PE	D
H	H	H	H	L	L	X	L

description

The SN75ALS161 eight-channel general-purpose interface bus transceiver is a monolithic, high-speed, Advanced Low-Power Schottky process device designed to provide the bus-management and data-transfer signals between operating units of a single controller instrumentation system. When combined with the SN75ALS160 octal bus transceiver, the SN75ALS161 provides the complete 16-wire interface for the IEEE 488 bus.

The SN75ALS161 features eight driver-receiver pairs connected in a front-to-back configuration to form input/output (I/O) ports at both the bus and terminal sides. The direction of data through these driver-receiver pairs is determined by the DC and TE enable signals.

The driver outputs (GPIB I/O ports) feature active bus-terminating resistor circuits designed to provide a high impedance to the bus when V_{CC} = 0. The drivers are designed to handle loads up to 48 milliamperes of sink current. Each receiver features p-n-p transistor inputs for high input impedance and a guaranteed hysteresis of 400 millivolts minimum for increased noise immunity. All receivers have 3-state outputs to present a high impedance to the terminal when disabled.

The SN75ALS161 is manufactured in a 20-pin package and is characterized for operation from 0°C to 70°C.

description

The SN75ALS163 octal general-purpose interface bus transceiver is a monolithic, high-speed, Advanced Low-Power Schottky device. It is designed for two-way data communications over single-ended transmission lines. The transceiver features driver outputs that can be operated in either the open-collector or three-state mode. If Talk Enable (TE) is high, these outputs have the characteristics of open-collector outputs when Pullup Enable (PE) is low and of three-state outputs when PE is high. Taking TE low places the outputs in the high-impedance state. The driver outputs are designed to handle loads of up to 48 milliamperes of sink current. Each receiver features p-n-p transistor inputs for high input impedance and 400 millivolts minimum of guaranteed hysteresis for increased noise immunity.

Output glitches during power-up and power-down are eliminated by an internal circuit that disables both the bus and receiver outputs. The outputs do not load the bus when $V_{CC} = 0$.

The SN75ALS163 is characterized for operation from 0°C to 70°C.

description

The SN75ALS164 eight-channel general-purpose interface bus transceiver is a monolithic, high-speed, Advanced Low-Power Schottky device designed to meet the requirements of IEEE Standard 488-1978. Each transceiver is designed to provide the bus-management and data-transfer signals between operating units of a multiple-controller instrumentation system. When combined with the SN75ALS160 octal bus transceiver, the SN75ALS164 provides the complete 16-wire interface for the IEEE 488 bus.

The SN75ALS164 features eight driver-receiver pairs connected in a front-to-back configuration to form input/output (I/O) ports at both the bus and terminal sides. All outputs are disabled (at a high-impedance state) during V_{CC} power-up and power-down transitions for glitch-free operation. The direction of data flow through these driver-receiver pairs is determined by the DC, TE, and SC enable signals. The SN75ALS164 is identical to the SN75ALS162 with the addition of an OR gate to help simplify board layouts in several popular applications. The ATN and EOI signals are ORed to pin 21, which is a standard totem-pole output.

NC—No internal connection.

CHANNEL IDENTIFICATION TABLE

NAME	IDENTITY	CLASS

SN75ALS164
OCTAL GENERAL-PURPOSE INTERFACE BUS TRANSCEIVER

ADVANCE
INFORMATION

The driver outputs (GPIO I/O ports) feature active bus-terminating resistor circuits designed to provide a high impedance to the bus when supply voltage V_{CC} is 0. The drivers are designed to handle loads up to 48 milliamperes of sink current. Each receiver features p-n-p transistor inputs for high input impedance and a guaranteed hysteresis of 400 millivolts minimum for increased noise immunity. All receivers have 3-state outputs to present a high impedance to the terminal when disabled.

The SN75ALS164 is manufactured in a 22-pin dual-in-line N package and in 24-pin DW package, and is characterized for operation from 0°C to 70°C.

ADVANCE INFORMATION

RECEIVE/TRANSMIT FUNCTION TABLE

CONTROLS				BUS-MANAGEMENT CHANNELS				DATA-TRANSFER CHANNELS			
SC	DC	TE	ATN [†]	ATN [†] (Controlled by DC)	SRQ	REN (Controlled by SC)	IFC	EOI	DAV	NDAC	NRFD (Controlled by TE)
	H	H	H	R	T			T	T	R	R
	H	H	L					R			
	L	L	H	T	R			R	R	T	T
	L	L	L					T			
	H	L	X	R	T			R	R	T	T
	L	H	X	T	R			T	T	T	R
H						T	T				
L						R	R				

H = high level, L = low level, R = receive, T = transmit, X = irrelevant

Direction of data transmission is from the terminal side to the bus side, and the direction of data receiving is from the bus side to the terminal side. Data transfer is noninverting in both directions.

[†]ATN is a normal transceiver channel that functions additionally as an internal direction control or talk enable for EOI whenever the DC and TE inputs are in the same state. When DC and TE are in opposite states, the ATN channel functions as an independent transceiver only.

description

The SN75ALS165 eight-channel general-purpose interface bus transceiver is a monolithic, high-speed, Advanced Low-Power Schottky device designed for two-way data communications over single-ended transmission lines. It is designed to meet the requirements of IEEE Standard 488-1978. The transceiver features driver outputs that can be operated in either the passive-pullup or three-state mode. If Talk Enable (TE) is high, these ports have the characteristics of passive-pullup outputs when Pullup Enable (PE) is low and of three-state outputs when PE is high. Taking TE low places these ports in the high-impedance state. Taking TE and PE low places both the drivers and receivers in the high-impedance state. The driver outputs are designed to handle loads up to 48 milliamperes of sink current.

An active turn-off feature has been incorporated into the bus-terminating resistors so that the device exhibits a high impedance to the bus when $V_{CC} = 0$. When combined with the SN75ALS161 or SN75ALS162 management bus transceiver, the pair provides the complete 16-wire interface for the IEEE 488 bus.

The SN75ALS165 is manufactured in a 20-pin package and is characterized for operation from 0°C to 70°C.

SN75ALS192 QUADRUPLE DIFFERENTIAL LINE DRIVERS

D2904, JULY 1985

- Meets EIA Standard RS-422-A
- High-Speed, Low-Power ALS Design
- 3-State TTL Compatible
- Single 5-V Supply Operation
- High Output Impedance in Power-Off Condition
- Complementary Output Enable Inputs
- Improved Replacement for the AM26LS31

SN75ALS192 . . . D, J, N DUAL-IN-LINE PACKAGE
(TOP VIEW)

description

This quadruple complementary-output line driver is designed for data transmission over twisted-pair or parallel-wire transmission lines. It meets the requirements of EIA Standard RS-422-A and is compatible with 3-state TTL circuits. Advanced Low-Power Schottky technology provides high speed without the usual power penalties. Standby supply current is typically only 26 milliamperes, while typical propagation delay time is less than 10 nanoseconds.

High-impedance inputs maintain input currents low, less than 1 microampere for a high level and less than 100 microamperes for a low level. Complementary control inputs, G and \bar{G} , allow these devices to be enabled at either a high input level or low input level. The SN75ALS192 is capable of data rates in excess of 20 megabits per second and is designed to operate with the SN75ALS193 quadruple line receiver.

The SN75ALS192 is characterized for operation from 0°C to 70°C.

logic diagram (positive logic)

description

The SN75ALS193 is a monolithic quadruple line receiver with three-state outputs designed using Advanced Low-Power Schottky technology. This technology provides combined improvements in bar design, tooling production, and wafer fabrication. This, in turn, provides significantly less power requirements and permits much higher data throughput than other designs. The device meets the specifications of EIA Standards RS-422-A and RS-423-A. It features three-state outputs that permit direct connection to a bus-organized system with a Fail-Safe design that ensures the outputs will always be high if the inputs are open.

The device is optimized for balanced multipoint bus transmission at rates up to 10 megabits per second. The input features high input impedance, input hysteresis for increased noise immunity, and an input sensitivity of ± 200 millivolts over a common-mode input voltage range of -7 to 7 volts. It also features active-high and active-low enable functions that are common to the four channels. The SN75ALS193 is designed for optimum performance when used with the SN75ALS192 quadruple differential line driver.

The SN75ALS193 is characterized for operation from 0°C to 70°C.

SN75ALS194 QUADRUPLE DIFFERENTIAL LINE DRIVER WITH 3-STATE OUTPUTS

D2917, OCTOBER 1985—REVISED OCTOBER 1986

- Meets EIA Standard RS-422-A
- High-Speed ALS Design
- 3-State TTL-Compatible
- Single 5-V Supply Operation
- High Output Impedance in Power-Off Condition
- Two Pairs of Drivers Independently Enabled
- Designed as a Replacement for the MC3487 with Improvements: I_{CC} 50% Lower, Switching Speed 30% Faster

FUNCTION TABLE (EACH DRIVER)

INPUT	OUTPUT ENABLE	OUTPUTS	
		Y	Z
H	H	H	L
L	H	L	H
X	L	High-Impedance	High-Impedance

H = TTL high level, L = TTL low level, X = irrelevant

description

This quadruple complementary-output line driver is designed for data transmission over twisted-pair or parallel-wire transmission lines. It meets the requirements of EIA Standard RS-422-A and is compatible with 3-state TTL circuits.

Advanced Low-Power Schottky technology provides high speed without the usual power penalty. Standby supply current is typically only 26 milliamperes, while typical propagation delay time is less than 10 nanoseconds and enable/disable times are typically less than 16 nanoseconds.

High-impedance inputs keep input currents low, less than 1 microampere for a high level and less than 100 microamperes for a low level. The driver circuits can be enabled in pairs by separate active-high enable inputs. The SN75ALS194 is capable of data rates in excess of 10 megabits per second and is designed to operate with the SN75ALS195 quadruple line receiver.

The SN75ALS194 is characterized for operation from 0°C to 70°C.

logic symbol†

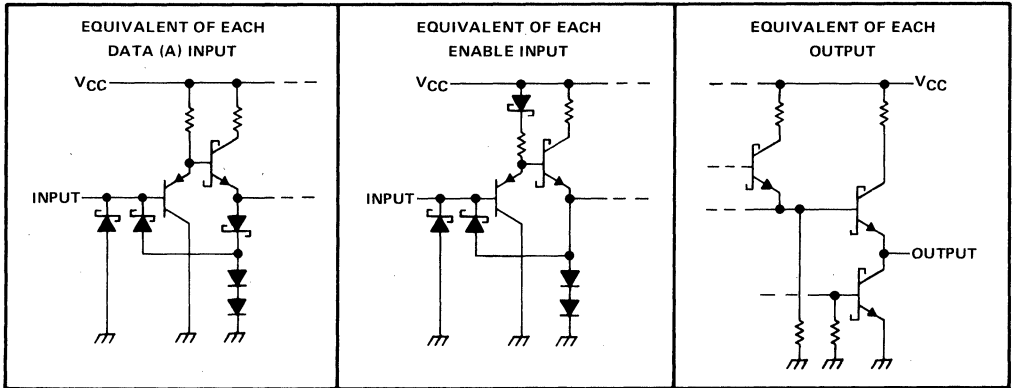

† This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

The SN75ALS195 is a monolithic quadruple line receiver with three-state outputs designed using Advanced Low-Power Schottky technology. This technology provides combined improvements in bar design, tooling production, and wafer fabrication, providing significantly less power consumption and permitting much higher data throughput than other designs. The device meets the specifications of EIA Standards RS-422-A and RS-423-A.

The SN75ALS195 features three-state outputs that permit direct connection to a bus-organized system with a fail-safe design that ensures the outputs will always be high if the inputs are open. The device is optimized for balanced multipoint bus transmission at rates up to 10 megabits per second. The input features high input impedance, input hysteresis for increased noise immunity, and an input sensitivity of ± 200 millivolts over a common-mode input voltage range of ± 7 volts. It also features an active-high enable function for each of two receiver pairs. The SN75ALS195 is designed for optimum performance when used with the SN75ALS194 quadruple differential line driver.

The SN75ALS195 is characterized for operation from 0°C to 70°C.

description

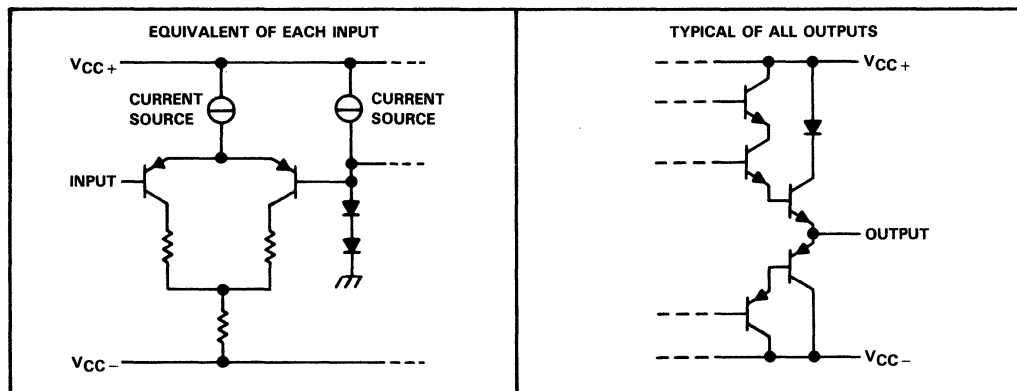

The uA9636AC is a dual single-ended line driver designed to meet EIA Standards RS-423-A and RS-232-C and Federal Standard 1030. The slew rates of both amplifiers are controlled by a single external resistor, R_{WS} , connected between the wave-shape-control terminal and ground. Output current limiting is provided. Inputs are compatible with TTL and CMOS and are diode-protected against negative transients. This device operates from ± 12 volts and is supplied in an 8-pin dual-in-line package.

The uA9636AC is characterized for operation from 0°C to 70°C.

description

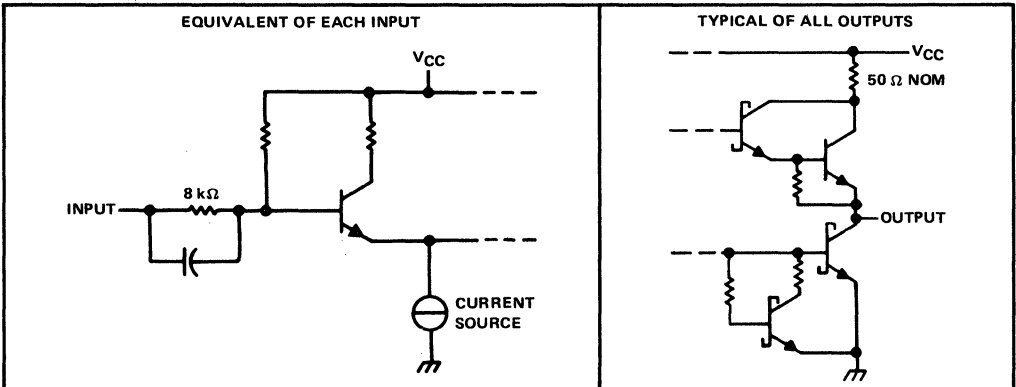

The uA9637AC is a dual differential line receiver designed to meet EIA standards RS-422-A and RS-423-A and Federal Standards 1020 and 1030. It utilizes Schottky circuitry and has TTL-compatible outputs. The inputs are compatible with either a single-ended or a differential-line system. This device operates from a single 5-volt power supply and is supplied in an 8-pin dual-in-line package and small outline package.

The uA9637AM is characterized over the full military temperature range of -55°C to 125°C . The uA9637AC is characterized for operation from 0°C to 70°C .

Line Drivers/Receivers

μA9639C DUAL DIFFERENTIAL LINE RECEIVER

D3009, OCTOBER 1986

- Meets EIA Standards RS-422-A and RS-423-A
- Meets Federal Standards 1020 and 1030
- Operates from Single 5-V Power Supply
- Wide Common-Mode Voltage Range
- High Input Impedance
- TTL-Compatible Outputs
- High-Speed Schottky Circuitry
- 8-Pin Dual-In-Line and "Small Outline" Packages
- Designed to be Interchangeable with Fairchild μA9639AC

D, JG, OR P PACKAGE
(TOP VIEW)

logic symbol†

† This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

description

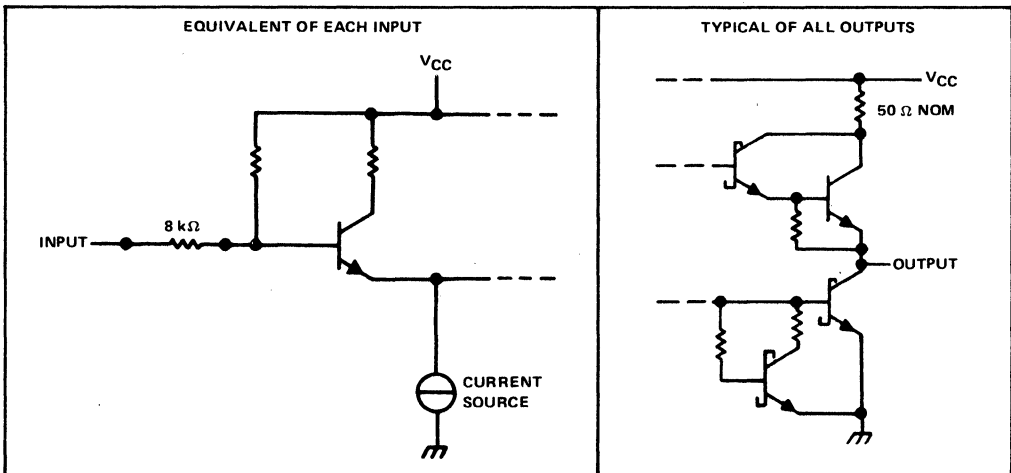

The μA9639C is a dual differential line receiver designed to meet EIA standards RS-422-A and RS-423-A and Federal Standards 1020 and 1030. It utilizes Schottky circuitry and has TTL-compatible outputs. The inputs are compatible with either a single-ended or a differential-line system. This device operates from a single 5-volt power supply and is supplied in an 8-pin dual-in-line package and "small outline" package.

The μA9639C is characterized for operation from 0°C to 70°C.

uA9639C DUAL DIFFERENTIAL LINE RECEIVER

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC} (see Note 1)	-0.5 V to 7 V
Input voltage	± 15 V
Differential input voltage (see Note 2)	± 15 V
Output voltage (see Note 1)	-0.5 V to 5.5 V
Low-level output current	50 mA
Continuous total dissipation at (or below) 25°C free-air temperature (see Note 3):	
D package	725 mW
JG package	825 mW
P package	1000 mW
Operating free-air temperature range	0°C to 70°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds: JG package	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: D and P package	260°C

- NOTES: 1. All voltage values, except differential input voltage, are with respect to the network ground terminal.
 2. Differential input voltage is measured at the noninverting input with respect to the corresponding inverting input.
 3. For operation above 25°C free-air temperature, derate the D package to 464 mW at 70°C at the rate of 5.8 mW/°C, the JG package to 528 mW at 70°C at the rate of 6.6 mW/°C, and the P package to 640 mW at 70°C at the rate of 8.0 mW/°C.

recommended operating conditions

	MIN	NOM	MAX	UNIT

DS3680 QUAD TELEPHONE RELAY DRIVER

D2758, MARCH 1986

- Designed for -52-V Battery Operation
- 50-mA Output Current Capability
- Input Compatible with TTL and CMOS
- High Common-Mode Input Voltage Range
- Very Low Input Current
- Fail-Safe Disconnect Feature
- Built-In Output Clamp Diode
- Direct Replacement for National DS3680 and Fairchild μ A3680

D, J OR N PACKAGE
(TOP VIEW)

description

The DS3680 telephone relay driver is a monolithic integrated circuit designed to interface -48-volt relay systems to TTL or other systems in telephone applications. It is capable of sourcing up to 50 milliamperes from standard -52-volt battery power. To reduce the effects of noise and IR drop between logic ground and battery ground, these drivers are designed to operate with a common-mode input range of ± 20 volts referenced to battery ground. The common-mode input voltages for the four drivers can be different, so a wide range of input elements can be accommodated. The high-impedance inputs are compatible with positive TTL and CMOS levels or negative logic levels. A clamp network is included in the driver outputs to limit high-voltage transients generated by the relay coil during switching. The complementary inputs ensure that the driver output will be "off" as a fail-safe condition when either output is open.

The DS3680 is characterized for operation from -25°C to 85°C.

description

The L293 is a quadruple high-current half-H driver designed to provide bidirectional drive currents of up to one ampere at voltages from 4.5 volts to 36 volts. It is designed to drive inductive loads such as relays, solenoids, dc and stepping motors, as well as other high-current/high-voltage loads in positive-supply applications.

All inputs are TTL-compatible. Each output is a complete totem-pole drive circuit with a Darlington transistor sink and a psuedo-Darlington source. Channels are enabled in pairs with channels 1 and 2 enabled by 1,2EN and channels 3 and 4 enabled by 3,4EN. When an enable input is high, the associated channels are enabled and their outputs are active and in phase with their inputs. When the enable input is low, those channels are disabled and their outputs are off and in a high-impedance state. With the proper data inputs, each pair of drivers form a full-H (or bridge) reversible drive suitable for solenoid or motor applications.

External high-speed output clamp diodes should be used for inductive transient suppression. A VCC1 terminal, separate from VCC2, is provided for the logic inputs to minimize device power dissipation.

The L293 is designed for operation from 0°C to 70°C.

logic symbol†

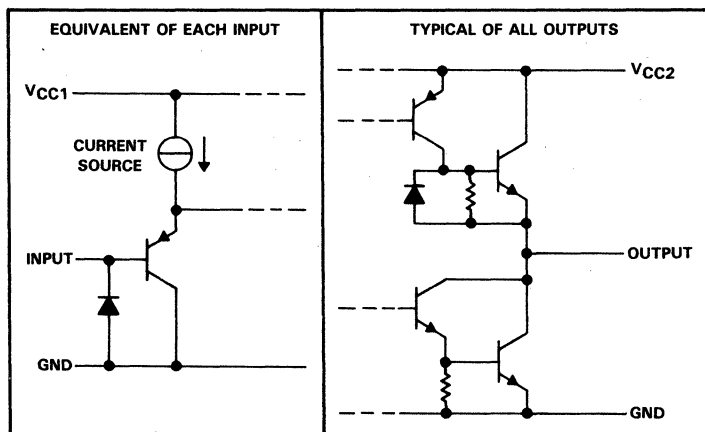

† This symbol is in accordance with ANSI/IEEE Std 91-1984 and IEC Publication 617-12.

logic diagram

schematics of inputs and outputs

5

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Logic supply voltage, V_{CC1} (see Note 1)	36 V
Output supply voltage, V_{CC2}	36 V
Input voltage	7 V
Output voltage range	-3 V to $V_{CC2} + 3$ V
Peak output current (nonrepetitive, $t \leq 5$ ms)	± 2 A
Continuous output current	± 1 A
Continuous total dissipation at (or below) 25°C free-air temperature (see Notes 2 and 3)	2075 mW
Continuous total dissipation at (or below) 25°C case temperature (see Note 3)	7375 mW
Continuous total dissipation at 80°C case temperature (see Note 3)	4130 mW
Operating case or virtual junction temperature range	-40°C to 150°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

- NOTES: 1. All voltage values are with respect to the network ground terminal.
 2. For operation above 25°C free-air temperature, derate linearly at the rate of 16.6 mW/°C.
 3. For operation above 25°C case temperature, derate linearly at the rate of 59 mW/°C. Due to variations in individual device electrical characteristics and thermal resistance, the built-in thermal overload protection may be activated at power levels slightly above or below the rated dissipation.

description

The L293D is a quadruple high-current half-H driver designed to provide bidirectional drive currents of up to 600 milliamperes at voltages from 4.5 volts to 36 volts. It is designed to drive inductive loads such as relays, solenoids, dc and stepping motors, as well as other high-current/high-voltage loads in positive-supply applications.

All inputs are TTL-compatible. Each output is a complete totem-pole drive circuit with a Darlington transistor sink and a psuedo-Darlington source. Channels are enabled in pairs with channels 1 and 2 enabled by 1,2EN and channels 3 and 4 enabled by 3,4EN. When an enable input is high, the associated channels are enabled and their outputs are active and in phase with their inputs. When the enable input is low, those channels are disabled and their outputs are off and in a high-impedance state. With the proper data inputs, each pair of drivers form a full-H (or bridge) reversible drive suitable for solenoid or motor applications.

A VCC1 terminal, separate from VCC2, is provided for the logic inputs to minimize device power dissipation.

The L293D is designed for operation from 0°C to 70°C.

- Internal Electrostatic Discharge Protection
- High Noise Immunity
- Direct Replacement for SGS L298

description

The L298 is a dual high-current full-H driver designed to provide bidirectional drive currents of up to two amperes at voltages from 5 volts to 46 volts. It is designed to drive inductive loads such as relays, solenoids, dc motors, stepping motors, and other high-current or high-voltage loads in positive-supply applications. All inputs are TTL compatible. Each output (Y) is a complete totem-pole drive with a Darlington transistor sink and a psuedo-Darlington source. Each full-H driver is enabled separately. Outputs 1Y1 and 1Y2 are enabled by 1EN and outputs 2Y1 and 2Y2 are enabled by 2EN. When an EN input is high, the associated channels are active. When an EN input is low, the associated channels are off (i.e., in the high-impedance state).

Each half of the device forms a full-H reversible driver suitable for solenoid or motor applications. The current in each full-H driver can be monitored by connecting a resistor between the sense output terminal 1E and ground and another resistor between sense output terminal 2E and ground.

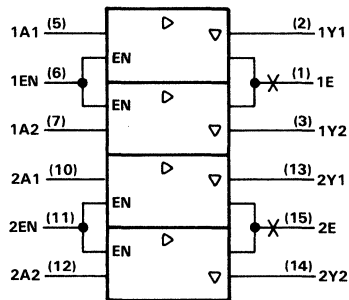

External high-speed output-clamp diodes should be used for inductive transient suppression. To minimize device power dissipation, a V_{CC1} supply voltage, separate from V_{CC2}, is provided for the logic inputs.

description

The PBL3717A is a high-current, high-voltage full-H reversible driver designed to control and drive one phase of a bipolar stepper motor. It is designed to provide bidirectional drive currents of up to one ampere at voltages from 10 volts to 46 volts in positive-supply applications. Two PBL3717A devices, with a few external components, form a complete two-phase bipolar stepper motor driver. All inputs are TTL-compatible. Each output (Y) forms a complete totem-pole drive with a Darlington transistor sink and a pseudo-Darlington source. Logic input pin DIR selects the direction of current flow in a load connected between outputs Y1 and Y2. A high level at the DIR input causes the load current to flow from output Y1 (source) to output Y2 (sink). A low level at the DIR input causes the load current to flow from output Y2 (source) to output Y1 (sink). When logic inputs I0 and I1 are both high, the Y1 and Y2 outputs are disabled and in the high-impedance state.

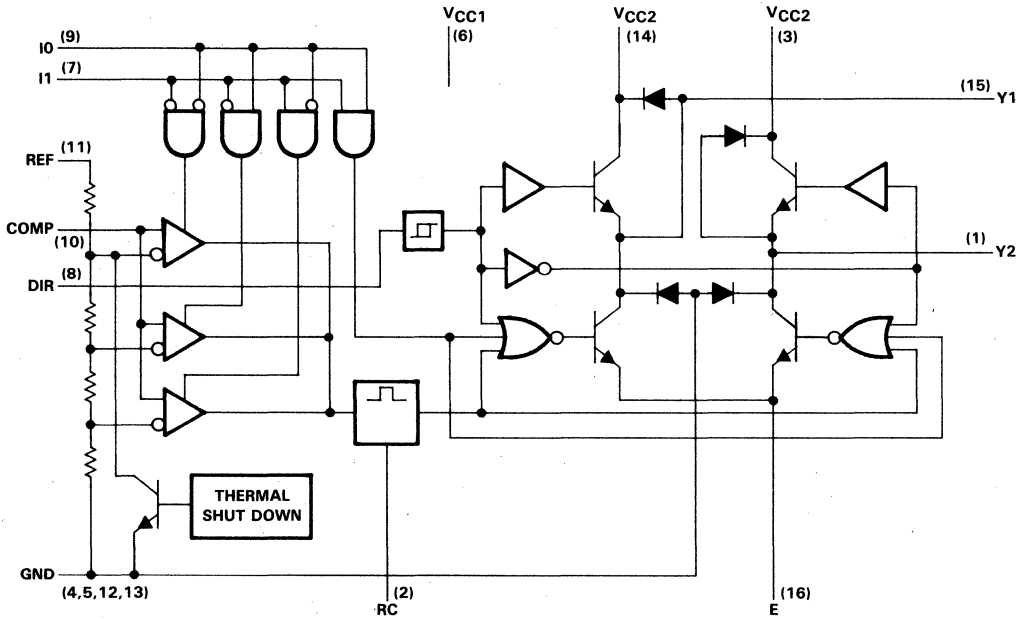

The current in the full-H driver load can be monitored by connecting a resistor between the sense output terminal E and ground. Voltage feedback from terminal E to the COMP input pin provides output current regulation via chop-mode operation of the sink output transistors. Three levels of output current can be selected by programming two logic inputs, I0 and I1, as shown in the function table. These inputs are internally decoded to enable one of three comparators to set the output current level to low, medium, or high. The precise level of output current is set by the comparator selected, the comparator reference voltage applied to the REF pin, the value of the sense resistor, and the sense output voltage fed back to the COMP input. When chop-mode current regulation is used, an internal monostable circuit, programmed by an external RC network at the RC pin, sets the current decay time.

The device contains built-in high-speed output clamp diodes for inductive transient protection. A separate supply voltage (VCC1) is provided for the logic input circuits to minimize device power dissipation. Supply voltage VCC2 is used for the output circuits. Both VCC2 supply pins should be connected together as close to the package as possible.

The PBL3717A is characterized for operation from 0°C to 70°C.

logic diagram (position logic)

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Output supply voltage, VCC2 (see Notes 1 and 2)	50 V
Logic supply voltage, VCC1	7 V
Logic input voltage	6 V
Comparator input voltage	VCC1
Reference voltage, Vref	15 V
Continuous output current	±1.2 A
Continuous total dissipation at (or below) 25°C free-air temperature (see Note 3)	2075 mW
Continuous total dissipation at (or below) 25°C case temperature (see Note 3)	7375 mW
Operating case or virtual junction temperature	0°C to 150°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from the case for 10 seconds	260°C

- NOTES: 1. All voltage values are with respect to the GND terminal.
 2. Both VCC2 pins must be connected together as close to the package as possible for optimum testing and operation of the device.
 3. For operation above 25°C free-air temperature, derate linearly at the rate of 16.6 mW/°C. For operation above 25°C case temperature, derate linearly at the rate of 59 mW/°C. To avoid exceeding the design maximum virtual junction temperature, these ratings should not be exceeded. Due to variations in individual device electrical characteristics and thermal resistance, the built-in thermal overload protection may be activated at power levels slightly above or below the rated dissipation.

description

The SN75064, SN75065, SN75066, and SN75067 are monolithic high-voltage, high-current Darlington transistor switches. Each comprises four n-p-n Darlington pairs. All units feature high-voltage outputs with common-cathode clamp diodes for switching inductive loads. Outputs and inputs may each be paralleled for higher current capability. Applications include relay drivers, hammer drivers, lamp drivers, display drivers (LED and gas discharge), line drivers, and logic buffers. These common-emitter circuits are designed to operate as current sinks to the load.

The SN75064 and SN75065 are intended for use with TTL and 5-volt MOS logic. The SN75066 and SN75067 are intended for use with PMOS and higher voltage CMOS logic.

The SN75064 thru SN75067 are characterized for operation from 0°C to 70°C.

description

The SN75068 and SN75069 are monolithic integrated circuits each consisting of four high-voltage, high-current n-p-n cascaded transistor switches. Each switch includes a first stage compatible with both TTL and 5-volt CMOS signal levels. The second and third stages form uncommitted-collector outputs with common-cathode clamp diodes for switching inductive loads.

The SN75068 and SN75069 can sink up to 1.5 amperes per switch. Applications include logic buffers, MOS drivers, memory drivers, line drivers, relay drivers, hammer drivers, lamp drivers, and display drivers (LED and gas discharge).

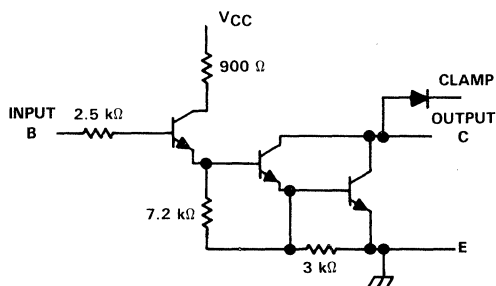

The SN75068 and SN75069 are characterized for operation from 0°C to 70°C.

- Output Supply Voltage Range Up to 24 V
- Low Standby Power Dissipation

description

The SN75372 is a dual NAND gate interface circuit designed to drive power MOSFETs from TTL inputs. It provides high current and voltage levels necessary to drive large capacitive loads at high speeds. The device operates from a VCC1 of 5 volts, and a VCC2 of up to 24 volts.

The SN75372 is characterized for operation from 0°C to 70°C.

APPLICATIONS INFORMATION

driving power MOSFETs

The drive requirements of power MOSFETs are much lower than comparable bipolar power transistors. The input impedance of a FET consists of a reverse biased PN junction that can be described as a large capacitance in parallel with a very high resistance. For this reason, the commonly used open-collector driver with a pull-up resistor is not satisfactory for high-speed applications. In Figure 12(a), an IRF151 power MOSFET switching an inductive load is driven by an open-collector transistor driver with a 470 Ω pull-up resistor. The input capacitance (C_{ISS}) specification for an IRF151 is 4000 pF maximum. The resulting long turn-on time due to the combination of C_{ISS} and the pull-up resistor is shown in Figure 12(b).

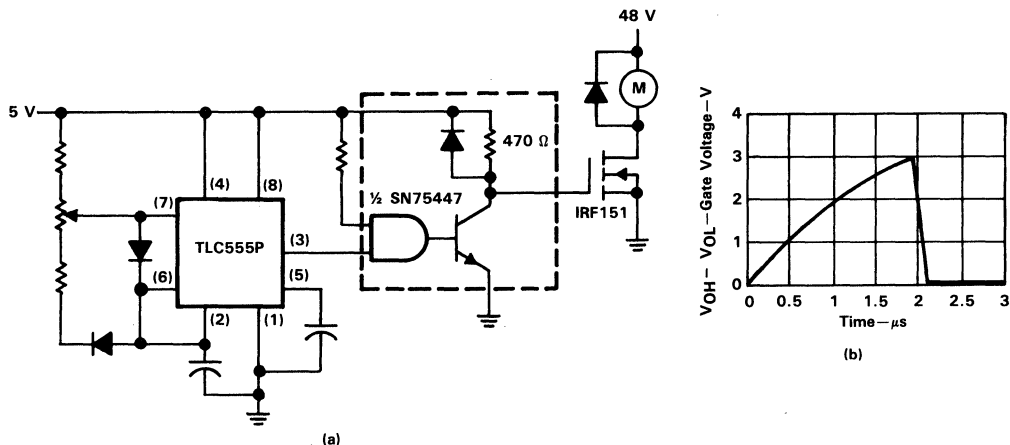

FIGURE 12. POWER MOSFET DRIVE USING SN75447

5

Peripheral Drivers/Actuators

SN75372 DUAL MOSFET DRIVER

APPLICATIONS INFORMATION

A faster, more efficient drive circuit uses an active pull-up as well as an active pull-down output configuration, referred to as a totem-pole output. The SN75372 driver provides the high speed, totem-pole drive desired in an application of this type, see Figure 13(a). The resulting faster switching speeds are shown in Figure 13(b).

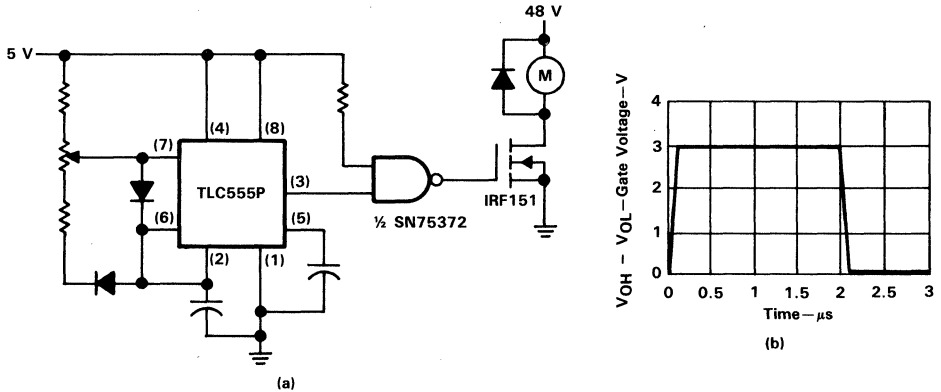

FIGURE 13. POWER MOSFET DRIVE USING SN75372

Power MOSFET drivers must be capable of supplying high peak currents to achieve fast switching speeds as shown by the equation

$$I_{pk} = \frac{VC}{t_r}$$

where C is the capacitive load, and t_r is the desired rise time. V is the voltage that the capacitance is charged to. In the circuit shown in Figure 13(a), V is found by the equation

$$V = V_{OH} - V_{OL}$$

Peak current required to maintain a rise time of 100 ns in the circuit of Figure 13(a) is

$$I_{PK} = \frac{(3-0)4(10^9)}{100(10^9)} = 120 \text{ mA}$$

Circuit capacitance can be ignored because it is very small compared to the input capacitance of the IRF151. With a V_{CC} of 5 V, and assuming worst-case conditions, the gate drive voltage is 3 V.

For applications in which the full voltage of V_{CC2} must be supplied to the MOSFET gate, the SN75374 QUAD MOSFET driver should be used.

THERMAL INFORMATION

power dissipation precautions

Significant power may be dissipated in the SN75372 driver when charging and discharging high-capacitance loads over a wide voltage range at high frequencies. Figure 5 shows the power dissipated in a typical SN75372 as a function of load capacitance and frequency. Average power dissipated by this driver is derived from the equation

$$P_{T(AV)} = P_{DC(AV)} + P_{C(AV)} + P_{S(AV)}$$

where $P_{DC(AV)}$ is the steady-state power dissipation with the output high or low, $P_{C(AV)}$ is the power level during charging or discharging of the load capacitance, and $P_{S(AV)}$ is the power dissipation during switching between the low and high levels. None of these include energy transferred to the load and all are averaged over a full cycle.

The power components per driver channel are

$$P_{DC(AV)} = \frac{P_H t_H + P_L t_L}{T}$$

$$P_{C(AV)} \approx C V_C^2 f$$

$$P_{S(AV)} = \frac{P_{LH} t_{LH} + P_{HL} t_{HL}}{T}$$

FIGURE 14. OUTPUT VOLTAGE WAVEFORM

where the times are as defined in Figure 14.

P_L , P_H , P_{LH} , and P_{HL} are the respective instantaneous levels of power dissipation, C is the load capacitance. V_C is the voltage across the load capacitance during the charge cycle shown by the equation

$$V_C = V_{OH} - V_{OL}$$

$P_{S(AV)}$ may be ignored for power calculations at low frequencies.

THERMAL INFORMATION

In the following power calculation, both channels are operating under identical conditions: $V_{OH} = 19.2$ volts and $V_{OL} = 0.15$ volts with $V_{CC1} = 5$ volts, $V_{CC2} = 20$ volts, $V_C = 19.05$ volts, $C = 1000$ picofarads, and the duty cycle = 60%. At 0.5 MHz, $P_{S(AV)}$ is negligible and can be ignored. When the output voltage is high, I_{CC2} is negligible and can be ignored.

On a per-channel basis using data sheet values

$$P_{DC(AV)} = \left[(5 \text{ V}) \left(\frac{2 \text{ mA}}{2} \right) + (20 \text{ V}) \left(\frac{0 \text{ mA}}{2} \right) \right] (0.6) + \left[(5 \text{ V}) \left(\frac{16 \text{ mA}}{2} \right) + (20 \text{ V}) \left(\frac{7 \text{ mA}}{2} \right) \right] (0.4)$$

$$P_{DC(AV)} = 47 \text{ mW per channel}$$

Power during the charging time of the load capacitance is

$$P_C(AV) = (1000 \text{ pF}) (19.05 \text{ V})^2 (0.5 \text{ MHz}) = 182 \text{ mW per channel}$$

Total power for each driver is

$$P_T(AV) = 47 \text{ mW} + 182 \text{ mW} = 229 \text{ mW}$$

and total package power is

$$P_T(AV) = (229) (2) = 458 \text{ mW.}$$

SN75374 QUADRUPLE MOSFET DRIVER

D3004, SEPTEMBER 1986

- Quadruple Circuits Capable of Driving High-Capacitance Loads at High Speeds
- Output Supply Voltage Range from 5 V to 24 V
- Low Standby Power Dissipation
- VCC3 Supply Maximizes Output Source Voltage

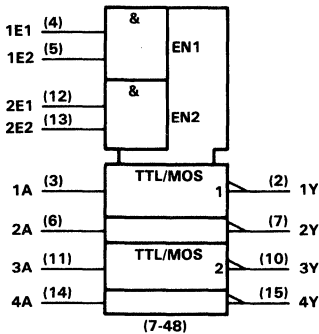

description

The SN75374 is a quadruple NAND interface circuit designed to drive power MOSFETs from TTL inputs. It provides the high current and voltage necessary to drive large capacitive loads at high speeds.

The outputs can be switched very close to the VCC2 supply rail when VCC3 is about 3 volts higher than VCC2. The VCC3 pin can also be tied directly to VCC2 when the source voltage requirements are lower.

The SN75374 is characterized for operation from 0°C to 70°C.

APPLICATIONS INFORMATION

driving power MOSFETs

The drive requirements of power MOSFETs are much lower than comparable bipolar power transistors. The input impedance of a FET consists of a reverse biased PN junction that can be described as a large capacitance in parallel with a very high resistance. For this reason, the commonly used open-collector driver with a pull-up resistor is not satisfactory for high-speed applications. In Figure 13(a), an IRF151 power MOSFET switching an inductive load is driven by an open-collector transistor driver with a 470 Ω pull-up resistor. The input capacitance (C_{iss}) specification for an IRF151 is 4000 pF maximum. The resulting long turn-on time due to the product of input capacitance and the pull-up resistor is shown in Figure 13(b).

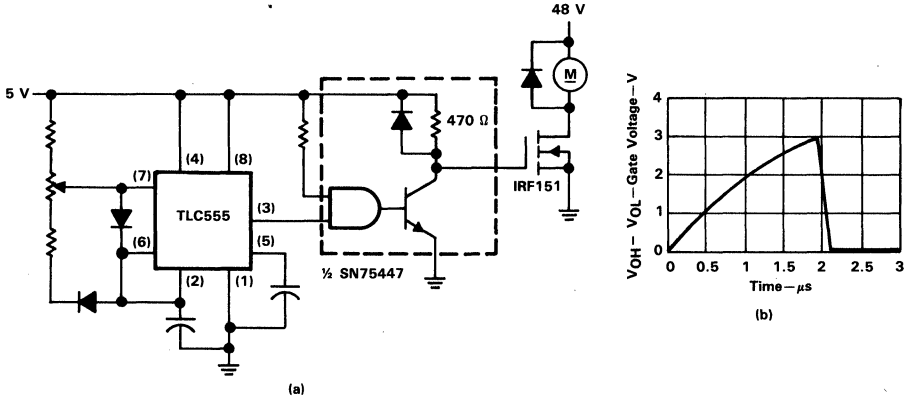

FIGURE 13. POWER MOSFET DRIVE USING SN75447

A faster, more efficient drive circuit uses an active pull-up as well as an active pull-down output configuration, referred to as a totem-pole output. The SN75374 driver provides the high-speed totem-pole drive desired in an application of this type, see Figure 14(a). The resulting faster switching speeds are shown in Figure 14(b).

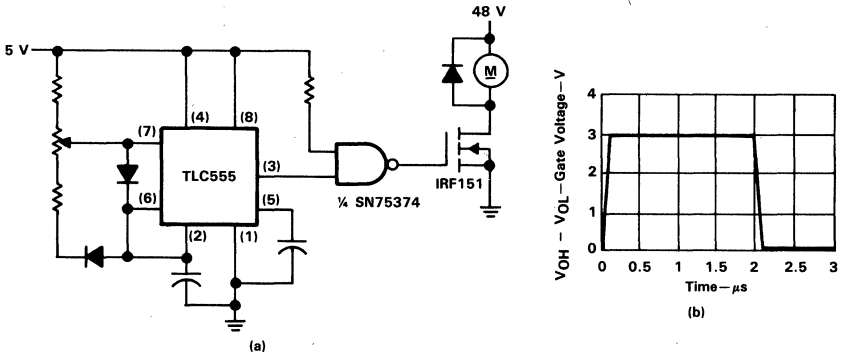

FIGURE 14. POWER MOSFET DRIVE USING SN75374

APPLICATIONS INFORMATION

Power MOSFET drivers must be capable of supplying high peak currents to achieve fast switching speeds as shown by the equation

$$I_{pk} = \frac{VC}{t_r}$$

where C is the capacitive load, and t_r is the desired rise time. V is the voltage that the capacitance is charged to. In the circuit shown in Figure 14(a), V is found by the equation

$$V = V_{OH} - V_{OL}$$

Peak current required to maintain a rise time of 100 ns in the circuit of Figure 14(a) is

$$I_{PK} = \frac{(3-0)4(10^9)}{100(10^9)} = 120 \text{ mA}$$

Circuit capacitance can be ignored because it is very small compared to the input capacitance of the IRF151. With a V_{CC} of 5 V, and assuming worst-case conditions, the gate drive voltage is 3 V.

For applications in which the full voltage of V_{CC2} must be supplied to the MOSFET gate, V_{CC3} should be at least 3 volts higher than V_{CC2} .

THERMAL INFORMATION

power dissipation precautions

Significant power may be dissipated in the SN75374 driver when charging and discharging high-capacitance loads over a wide voltage range at high frequencies. Figure 12 shows the power dissipated in a typical SN75374 as a function of frequency and load capacitance. Average power dissipated by this driver is derived from the equation

$$P_{T(AV)} = P_{DC(AV)} + P_{C(AV)} + P_{S(AV)}$$

where $P_{DC(AV)}$ is the steady-state power dissipation with the output high or low, $P_{C(AV)}$ is the power level during charging or discharging of the load capacitance, and $P_{S(AV)}$ is the power dissipation during switching between the low and high levels. None of these include energy transferred to the load and all are averaged over a full cycle.

The power components per driver channel are

$$P_{DC(AV)} = \frac{P_H t_{LH} + P_L t_{tL}}{T}$$

$$P_{C(AV)} \approx C V^2 C f$$

$$P_{S(AV)} = \frac{P_{LH} t_{LH} + P_{HL} t_{tHL}}{T}$$

FIGURE 15. OUTPUT VOLTAGE WAVEFORM

where the times are as defined in Figure 15.

SN75374 QUADRUPLE MOSFET DRIVER

THERMAL INFORMATION

P_L , P_H , P_{LH} , and P_{HL} are the respective instantaneous levels of power dissipation, C is the load capacitance. V_C is the voltage across the load capacitance during the charge cycle shown by the equation

$$V_C = V_{OH} - V_{OL}$$

$P_S(AV)$ may be ignored for power calculations at low frequencies.

$P_S(AV)$ may be ignored for power calculations at low frequencies.

In the following power calculation, all four channels are operating under identical conditions: $f = 0.2$ MHz, $V_{OH} = 19.9$ volts and $V_{OL} = 0.15$ volts with $V_{CC1} = 5$ volts, $V_{CC2} = 20$ volts, $V_{CC3} = 24$ volts, $V_C = 19.75$ volts, $C = 1000$ picofarads, and the duty cycle = 60%. At 0.2 MHz for $C_L < 2000$ pF, $P_S(AV)$ is negligible and can be ignored. When the output voltage is low, I_{CC2} is negligible and can be ignored.

On a per-channel basis using data sheet values

$$P_{DC(AV)} = \left[(5 \text{ V}) \left(\frac{4 \text{ mA}}{4} \right) + (20 \text{ V}) \left(\frac{-2.2 \text{ mA}}{4} \right) + (24 \text{ V}) \left(\frac{2.2 \text{ mA}}{4} \right) \right] (0.6) + \left[(5 \text{ V}) \left(\frac{31 \text{ mA}}{4} \right) + (20 \text{ V}) \left(\frac{0 \text{ mA}}{4} \right) + (24 \text{ V}) \left(\frac{16 \text{ mA}}{4} \right) \right] (0.4)$$

$$P_{DC(AV)} = 58.2 \text{ mW per channel}$$

Power during the charging time of the load capacitance is

$$P_C(AV) = (1000 \text{ pF}) (19.75 \text{ V})^2 (0.2 \text{ MHz}) = 78 \text{ mW per channel}$$

Total power for each driver is

$$P_T(AV) = 58.2 \text{ mW} + 78 \text{ mW} = 136.2 \text{ mW}$$

The total package power is

$$P_T(AV) = (136.2) (4) = 544.8 \text{ mW}$$

description

The SN75407 and SN75408 dual peripheral drivers are designed for use in systems that require high current, high voltage, and fast switching outputs. These devices have diode-clamped inputs as well as high-current, high-voltage output clamp diodes for switching inductive loads. Special circuits enable these devices to feature very low quiescent power and minimal input current requirements. Applications include logic buffers, hammer drivers, dc motor drivers, and dc relay/solenoid drivers.

The SN75407 and SN75408 are characterized for operation from 0°C to 70°C.

description

The SN75435 quadruple peripheral driver is designed for use in systems requiring high current, high voltage, and high load power. It features four inverting open-collector drivers with a common enable input that, when taken low, disables all four outputs. Each driver is protected against load shorts with its own latching over-current shutdown circuitry, which will turn the output off when a load short is detected. A short on one load will not affect operation of the other three drivers. The latch for the shutdown will hold the output off until the input or enable pin is taken low and then high again. A delay circuit is incorporated in the over-current shutdown to allow load capacitance of up to 5 nF at 35 volts.

Applications include relay drivers, lamp drivers, solenoid drivers, motor drivers, LED drivers, line drivers, logic buffers, hammer drivers, and memory drivers.

The SN75435 is characterized for operation from 0°C to 70°C.

description

Series 75446 dual peripheral drivers are designed for use in systems that require high current, high voltage, and fast switching times. The SN75446, SN75447, SN75448, and SN75449 provide AND, NAND, OR, and NOR drivers, respectively. These devices have diode-clamped inputs as well as high-current, high-voltage inductive-clamp diodes on the outputs.

Series 75446 drivers are characterized for operation from 0°C to 70°C.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC} (see Note 1)	7 V
Input voltage	5.5 V
Output current (see Note 2)	400 mA
Output clamp diode current	400 mA
Continuous total dissipation at (or below)	
25°C free-air temperature (see Note 3): D package	725 mW
P package	1200 mW
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

- NOTES: 1. Voltage values are with respect to network ground terminal.
 2. Both halves of this dual circuit may conduct rated current simultaneously; however, power dissipation averaged over a short time interval must fall within the continuous dissipation ratings.
 3. For operation above 25°C free-air temperature, derate the D package at the rate of 5.8 mW/°C and the P package at the rate of 9.6 mW/°C.

description

Series 55450B/75451B dual peripheral drivers are a family of versatile devices designed for use in systems that employ TTL logic. This family is functionally interchangeable with and replaces the 75450 family and the 75450A family devices manufactured previously. The speed of the 55450B/75451B family is equal to that of the 75450 family, and the parts have been designed to ensure freedom from latch-up. Diode-clamped inputs simplify circuit design.

DUAL PERIPHERAL DRIVERS**

description (cont'd)

Typical applications include high-speed logic buffers, power drivers, relay drivers, lamp drivers. MOS drivers, line drivers, and memory drivers.

The SN55450B is a unique general-purpose device, featuring two standard Series 54 TTL gates and two uncommitted, high-current, high-voltage n-p-n transistors. The device offers the system designer the flexibility of tailoring the circuit to the application.

The SN55451B/SN75451B, SN55452B/SN75452B, SN55453B/SN75453B, and SN55454B/SN75454B are dual peripheral AND, NAND, OR, and NOR drivers, respectively, (assuming positive logic), with the output of the logic gates internally connected to the bases of the n-p-n output transistors.

Series 55450B drivers are characterized for operation over the full military range of -55°C to 125°C . Series 75451B drivers are characterized for operation from 0°C to 70°C .

D2218, DECEMBER 1976—REVISED SEPTEMBER 1986

PERIPHERAL DRIVERS FOR HIGH-VOLTAGE, HIGH-CURRENT DRIVER APPLICATIONS

- Characterized for Use to 300 mA
- High-Voltage Outputs
- No Output Latch-Up at 30 V (After Conducting 300 mA)
- Medium-Speed Switching
- Circuit Flexibility for Varied Applications and Choice of Logic Function
- TTL-Compatible Diode-Clamped Inputs
- Standard Supply Voltages
- New Plastic DIP (P) with Copper Lead Frame for Cooler Operation and Improved Reliability
- Package Options Include Plastic "Small Outline" Packages, Ceramic Chip Carriers, and Standard Plastic and Ceramic 300-mil DIPs

SN75463	OR	D,P

description

These dual peripheral drivers are functionally interchangeable with SN55451B through SN55454B and SN75451B through SN75453B peripheral drivers, but are designed for use in systems that require higher breakdown voltages than those devices can provide at the expense of slightly slower switching speeds. Typical applications include logic buffers, power drivers, relay drivers, lamp drivers, MOS drivers, line drivers, and memory drivers.

The SN55461/SN75461, SN55462/SN75462, SN55463/SN75463, and SN55464 are dual peripheral AND, NAND, OR, and NOR drivers, respectively, (assuming positive logic), with the output of the gates internally connected to the bases of the n-p-n output transistors.

Series 55461 drivers are characterized for operation over the full military temperature range of -55°C to 125°C ; Series 75461 drivers are characterized for operation from 0°C to 70°C .

DUAL PERIPHERAL DRIVERS**

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

	SN55461 SN55462 SN55463 SN55464	SN75461 SN75462 SN75463	UNIT
Supply voltage, V_{CC} (see Note 1)	7	7	V
Input voltage	5.5	5.5	V
Interemitter voltage (see Note 2)	5.5	5.5	V
Off-state output voltage	35	35	V
Continuous collector or output current (see Note 3)	400	400	mA
Peak collector or output current ($t_W \leq 10$ ms, duty cycle $\leq 50\%$, see Note 3)	500	500	mA
Continuous total dissipation at (or below) 25°C free-air temperature (see Note 4)	D package	725	mW
	FK package	1375	
	JG package	1050	
	P package	1200	
Operating free-air temperature range	-55 to 125	0 to 70	°C
Storage temperature range	-65 to 150	-65 to 150	°C
Case temperature for 60 seconds	FK package	260	°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds	JG package	300	°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	D or P package	260	°C

- NOTES: 1. Voltage values are with respect to network ground terminal unless otherwise specified.
2. This is the voltage between two emitters of a multiple-emitter transistor.
3. Both halves of these dual circuits may conduct rated current simultaneously; however, power dissipation averaged over a short time interval must fall within the continuous dissipation rating.
4. For operation above 25°C free-air temperature, refer to the Dissipation Derating Table.

DISSIPATION DERATING TABLE

PACKAGE	POWER RATING	DERATING FACTOR	ABOVE T_A
D	725 mW	5.8 mW/°C	25°C

HIGH-VOLTAGE HIGH-CURRENT DARLINGTON TRANSISTOR ARRAYS

- 500 mA Rated Collector Current (Single Output)
- High-Voltage Outputs . . . 100 V
- Output Clamp Diodes
- Inputs Compatible with Various Types of Logic
- Relay Driver Applications
- Higher-Voltage Versions of ULN2005A, ULN2001A, ULN2002A, ULN2003A, and ULN2004A, Respectively, for Commercial Temperature Range

D OR N PACKAGE
(TOP VIEW)

description

The SN75465, SN75466, SN75467, SN75468, and SN75469 are monolithic high-voltage, high-current Darlington transistor arrays. Each consists of seven n-p-n Darlington pairs that feature high-voltage outputs with common-cathode clamp diodes for switching inductive loads. The collector-current rating of each Darlington pair is 500 milliamperes. The Darlington pairs may be paralleled for higher current capability. Applications include relay drivers, hammer drivers, lamp drivers, display drivers (LED and gas discharge), line drivers, and logic buffers.

The SN75465 has a 1050-ohm series base resistor and is especially designed for use with TTL where higher current is required and loading of the driving source is not a concern. The SN75466 is a general-purpose array and may be used with TTL, P-MOS, CMOS, and other MOS technologies. The SN75467 is specifically designed for use with 14- to 25-volt P-MOS devices and each input has a zener diode and resistor in series to limit the input current to a safe limit. The SN75468 has a 2700-ohm series base resistor for each Darlington pair for operation directly with TTL or 5-volt CMOS. The SN75469 has a 10.5-kilohm series base resistor to allow its operation directly from CMOS or P-MOS that use supply voltages of 6 to 15 volts. The required input current is below that of the SN75468 and the required voltage is less than that required by the SN75467.

SN75473	OR	D,P

description

Series 55471/75471 dual peripheral drivers are functionally interchangeable with Series 55451B/75451B and Series 55461/75461 peripheral drivers, but are designed for use in systems that require higher breakdown voltages than either of those series can provide at the expense of slightly slower switching speeds than Series 55451B/75451B (limits are the same as Series 55461/75461). Typical applications include logic buffers, power drivers, relay drivers, lamp drivers, MOS drivers, line drivers, and memory drivers.

The SN55471/SN75471, SN55472/SN75472, SN55473/SN75473, and SN55474 are dual peripheral AND, NAND, OR, and NOR drivers, respectively, (assuming positive logic) with the output of the logic gates internally connected to the bases of the n-p-n output transistors.

Series 55471 drivers are characterized for operation over the full military temperature range of -55°C to 125°C . Series 75471 drivers are characterized for operation from 0°C to 70°C .

description

Series 75476 dual peripheral drivers are designed for use in systems that require high current, high voltage, and fast switching times. The SN75476, SN75477, SN75478, and SN75479 provide AND, NAND, OR, and NOR drivers, respectively. These devices have diode-clamped inputs as well as high-current, high-voltage clamp diodes on the outputs for inductive transient protection.

The SN75476, SN75477, SN75478, and SN75479 drivers are characterized for operation from 0°C to 70°C.

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

SN75603, SN75604, SN75605 HIGH-CURRENT HALF-H DRIVERS

D2832, MARCH 1984—REVISED OCTOBER 1986

- Three-State Outputs
- Continuous Output Current of ± 2 A
- Outputs Can Switch 40 V
- Transient Suppression
- Thermal Shutdown
- Inputs Compatible with TTL and 5-V CMOS
- VCC Range: 8 V to 40 V

KC, KH, AND KV PACKAGES

description

The SN75603, SN75604, and SN75605 are high-current half-H drivers designed for high-current switching of bidirectional loads at voltages from 8 V to 40 V. The devices are ideal for the switching of bidirectional dc and stepping motors.

FUNCTION TABLE

INPUTS		OUTPUT		
EN	DIR	SN75603	SN75604	SN75605
L	L	Z	Z	L
L	H	Z	Z	Z
H	L	L	H	Z
H	H	H	L	H

The SN75603 and SN75604 are designed to be used together in pairs, which eliminates the need for additional control logic. The SN75605 is a functional replacement for Sprague UDN2949. By controlling the enable and direction inputs, these devices may be placed in the high-impedance output state.

FIGURE 6

TYPICAL APPLICATIONS INFORMATION

SN75603 and SN75604 in speed-controlled, reversible dc motor drive

The SN75603 and SN75604 are recommended for continuous current applications of up to 2 amperes. The application shown in Figure 7 illustrates a reversible dc motor drive circuit with adjustable speed control. The DIR inputs for these drivers are complementary and therefore may be tied together and driven from the same logic control for bidirectional motor drive. The enables (EN) are tied together and driven by a pulse-width-modulated generator providing "on" duty cycles of 10% to 90% for speed control. A separate enable control is provided through a SN7409 logic gate.

SN75603, SN75604, SN75605 HIGH-CURRENT HALF-H DRIVERS

TYPICAL APPLICATIONS INFORMATION

power solenoid drive

The SN75603, SN75604, and SN75605, with up to 70 watts of output drive capability, are ideal for driving high-power solenoids. In applications that require high drive currents, these devices may be used as individual drivers or combined for bidirectional drive applications. A typical application would be a power solenoid operating a fluid-flow-control valve.

Figure 8 shows the SN75603 and the inverting SN75604 in a basic drive configuration for a reversing power solenoid.

description

The SN75608 is a high-current dual flux-regulating actuator designed for switching double-ended loads with currents up to 2.5 amperes at differential supply voltages from 30 volts to 60 volts. It is designed to drive and control the electromagnetic flux in printheads, solenoids, relays, and other loads whose inductance value varies during operation.

The SN75608 performs the function of flux regulation under control of standard TTL or CMOS input signals for two independent channels. Flux is proportional to the integral of the inductive-load voltage. It is a function of the total amount of current in the load and is the magnetic field maintained in the load. With flux regulation, the load current will vary to compensate for core saturation, temperature changes, and other variations of load inductance during operation while maintaining controlled, relatively constant flux in the load.

Each channel has separate sink and source driver outputs for driving each end of the inductive load. Internal feedback, consisting of an integrator and voltage comparator, provides flux regulation via chop-mode operation of the source output. The integrator circuit provides current to the capacitor terminal (CAP) proportional to the differential voltage between the sink and source outputs for each channel. The integrator requires an external capacitor connected between the CAP and V_{EE} terminals. The voltage at the CAP terminal, referenced to V_{EE} , is proportional to the integral of the source to sink (load) voltage.

The feedback path is completed by a differential voltage comparator that controls the state of the source output. The inverting comparator input is connected to the CAP terminal, and the noninverting input is connected to an analog voltage, $V_{ref}(TC)$, which is referenced to V_{EE} . $V_{ref}(TC)$ is proportional to the Threshold Control (TC) voltage, which is referenced to ground. The comparator hysteresis controls the charge and discharge voltage excursions at the CAP terminal and thus controls the on and off time of the source output chopper.

description (continued)

The SN75608 features built-in thermal protection and a sink output over-current sensor to prevent damage to the device. The outputs are disabled under low- V_{CC} or low- V_{EE} supply-voltage conditions to prevent transient output turn-on during power-up or power-down. The TC input is a combined threshold and logic input that disables the outputs when the TC input voltage is less than 0.8 V. This permits an external RC time delay at the TC input during logic system power-up to allow logic at input A to stabilize without causing undesired output turn-on. When a fault condition is detected by any one of these five protection features, the RS latch for each channel is set. The fault condition must be removed and the A input taken high before the RS latch will reset, reactivating the channel.

The SN75608 is characterized for operation from -20°C to 85°C .

DRIVER FUNCTION TABLE (EACH CHANNEL)

INPUTS			OUTPUTS		OPERATING MODE	COMMENTS
A	TC	CAP	SOURCE	SINK		
X	$\leq 0.8\text{ V}$	X	OFF	OFF	Disabled	TC acts as a digital input referenced to GND
H	$\geq 2\text{ V}$	X	OFF	OFF	Active	TC acts as an analog input referenced to GND (See Note 1)
L	$\geq 2\text{ V}$	$< V_{T+}$	ON	ON		
L	$\geq 2\text{ V}$	$> V_{T-}$	OFF	ON		

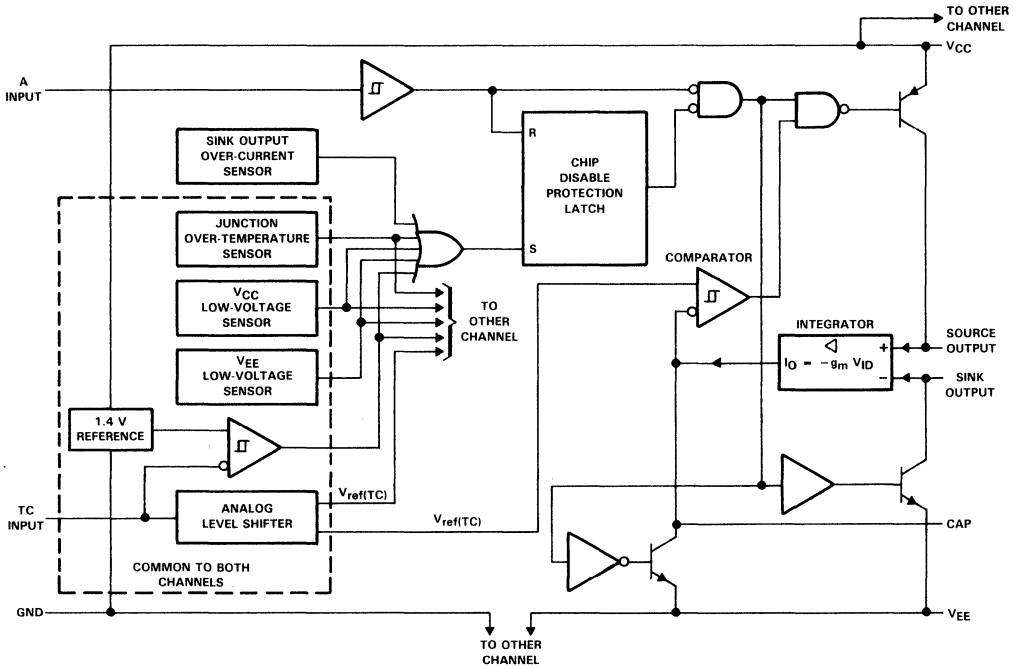

INTEGRATOR FUNCTION TABLE (EACH CHANNEL)

VOLTAGE INPUTS		CAP VOLTAGE	DIFFERENTIAL VOLTAGE $V_{O(\text{SOURCE})} - V_{O(\text{SINK})}$	CAP TERMINAL (See schematic)	INTEGRATOR MODE OF OPERATION
A	TC				
X	$\leq 0.8\text{ V}$	X	X	Q1 Sinking	Reset (Disabled)
H	$\geq 2\text{ V}$	X	X	Q1 Sinking	Reset
L	$\geq 2\text{ V}$	X	$\geq 300\text{ mV}$	Q2 Sourcing	Charge
L	$\geq 2\text{ V}$	$> V_{T-}$	$\leq -300\text{ mV}$	Q3 Sinking	Discharge

H = high level; L = low level; X = irrelevant

NOTE 1: The TC input has an operating range from 0 V to 6 V, but its effect on the CAP terminal is linear from approximately 2 V to 6 V. The best linearity is achieved within the recommended operating linear range.

logic diagram (each channel, positive logic)

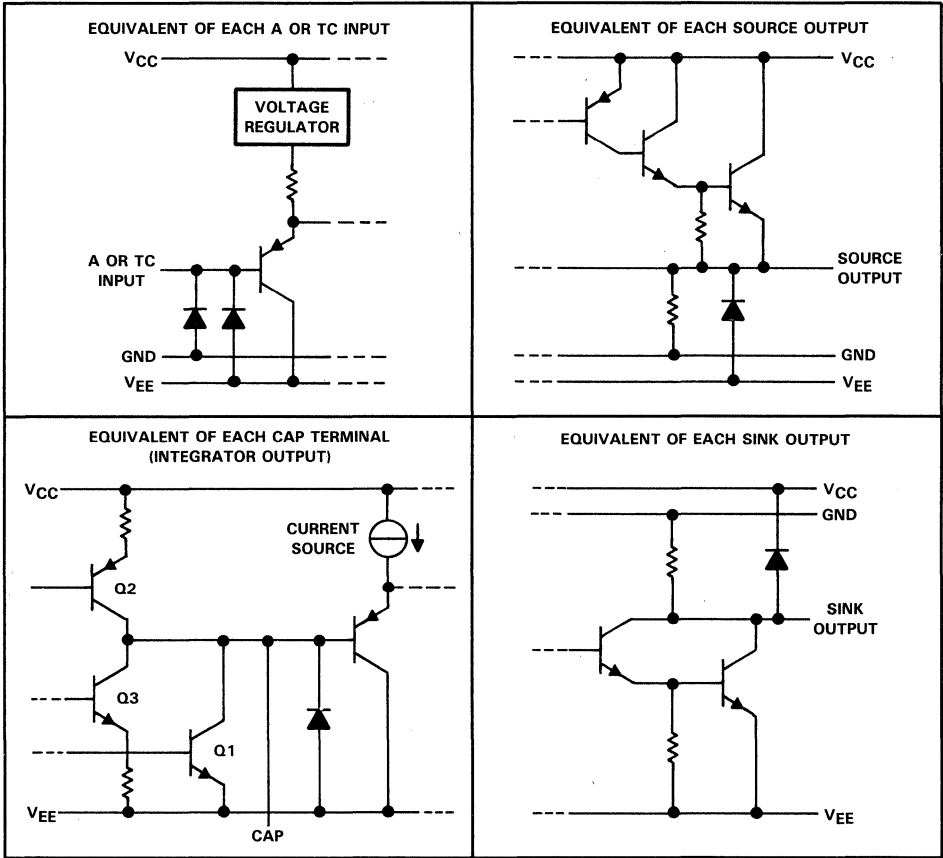

ADVANCE INFORMATION

Peripheral Drivers/Actuators

schematics of inputs and outputs

absolute maximum ratings over operating temperature range (unless otherwise noted)

Supply voltage range, V_{CC} (see Notes 2 and 3)	-0.3 V to 60 V
Supply voltage range, V_{EE} (see Note 3)	-60 V to 0.3 V
Voltage difference range between supply voltages, $V_{CC} - V_{EE}$	-0.3 V to 60 V
Input voltage range, V_I , A and TC inputs (see Note 4)	-1.6 V to $V_{EE} + 60$ V
CAP terminal range, $V_{(CAP)}$	$V_{EE} - 0.3$ V to V_{CC}
Source output voltage range, $V_{O(SRC)}$ (see Note 4)	$V_{EE} - 3$ V to $V_{CC} + 0.3$ V
Sink output voltage range, $V_{O(SNK)}$ (see Note 4)	$V_{EE} - 0.3$ V to $V_{CC} + 4$ V
Input current, I_I , A and TC inputs	-15 mA
Peak output current, source and sink outputs (nonrepetitive, $t_W \leq 100 \mu s$), I_{OM}	± 3 A
Continuous dissipation at (or below) 90°C case temperature (see Note 5)	20 W
Continuous dissipation at (or below) 25°C free-air temperature (see Note 5)	3.575 W
Operating case or virtual junction temperature range	-20°C to 150°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from the case for 10 seconds	260°C

- NOTES: 2. All voltage values, except differential voltages, are with respect to the network ground terminal.
 3. Both V_{CC} pins must be connected together as close to the package as possible for optimum testing and operation of the device. V_{EE} pins are handled in a like manner.
 4. The maximum current limitation at this terminal generally occurs at a voltage of lower magnitude than the voltage limit. Neither the maximum current nor the maximum voltage for this terminal should be exceeded.
 5. For operation above 25°C free-air temperature, derate linearly at the rate of 28.6 mW/°C. For operation above 90°C case temperature, derate linearly at the rate of 333 mW/°C. To avoid exceeding the design maximum virtual junction temperature, these ratings should not be exceeded. Due to variations in individual device electrical characteristics and thermal resistance, the built-in thermal overload protection may be activated at power levels slightly above or below the rated dissipation.

recommended operating conditions

	MIN	MAX	UNIT
Supply voltage, V_{CC}	15	30	V
Supply voltage, V_{EE}	-15	-30	V
Voltage difference between supply voltages, $V_{CC} - V_{EE}$	30	60	V
High-level input voltage at A, V_{IH}	2	7	V
Low-level input voltage at A, V_{IL}	-0.3 [†]	0.8	V
Linear-range TC input voltage (see Note 1)	2	6	V
Continuous output current, I_O		± 1	A
Peak output current at 40% duty cycle, I_O		± 2.5	A
Operating virtual junction temperature, T_J	-20	125	°C

[†] The algebraic convention, in which the least positive (most negative) designated minimum, is used in this data sheet for logic voltage levels.
 NOTE 1: The TC input has a operating range from 0 V to 6 V, but its effect on the CAP terminal is linear from approximately 2 V to 6 V. The best linearity is achieved within the recommended operating linear range.

electrical characteristics over recommended ranges of V_{CC}, V_{EE}, and virtual junction operating temperature (unless otherwise noted)

PARAMETER		TEST CONDITIONS		MIN	TYP [†]	MAX	UNIT
V _{IK}	Input clamp voltage at A or TC	I _I = -12 mA			-0.9	-1.5	V
V _{O(on)}	On-state output voltage	Source output	I _O = -1 A	See Note 6	V _{CC} - 2.8	V _{CC} - 1.9	V
			I _O = -2.5 A		V _{CC} - 3.7	V _{CC} - 2.5	
		Sink output	I _O = 1 A		V _{EE} + 1.8	V _{EE} + 1.2	
			I _O = 2.5 A		V _{EE} + 3	V _{EE} + 2	
V _(CAP)	CAP terminal output voltage	I _(CAP) = 1 mA, Reset mode	V _{EE} + 0.4	V _{EE} + 0.2		V	
V _{OK(SRC)}	Source output clamp voltage	I _O = -1 A	See Note 6	V _{EE} - 1.1	V _{EE} - 1.6	V	
		I _O = -2.5 A		V _{EE} - 1.5	V _{EE} - 2.2		
V _{OK(SNK)}	Sink output clamp voltage	I _O = 1 A	See Note 6	V _{CC} + 1.4	V _{CC} + 2.1		
		I _O = 2.5 A		V _{CC} + 2.2	V _{CC} + 3.3		
I _{O(off)}	Off-state output current	Source output	V _O = V _{EE}	-0.4	-2	mA	
		Sink output	V _O = V _{CC}	0.3	1		
I _{IH}	High-level input current at A	V _I = 5.5 V				10	μA
I _{IL}	Low-level input current at A	V _I = 0				-10	μA
I _I	Input current at TC	V _I = 0 to 6 V				±10	μA
I _(CAP)	Current at CAP terminal	Reset mode	V _(CAP) = V _{EE} + 1 V to V _{EE} + 6 V	1	4		mA
		Charge mode	V _I (TC) = 5 V, V _(CAP) = V _{EE} + 2 V, R _L = 1 kΩ from Source to Sink		-115		
		Discharge mode	V _I (TC) = 2 V, V _(CAP) = V _{EE} + 5 V, I _O (SRC) = -10 mA, I _O (SNK) = 10 mA		5		
V _{T+}	Positive-going threshold voltage at CAP terminal (charge mode)	R _L = 1 kΩ from Source to Sink, V _I (TC) = 2 V to 6 V	See Notes 7 and 8	V _I (TC)			
V _{T-}	Negative-going threshold voltage at CAP terminal (discharge mode)			0.95 V _I (TC)			
V _{hys} V _{T+}	Normalized hysteresis at CAP Terminal [(V _{T+} - V _{T-})/V _{T+}]			See Notes 7, 8, and 9		0.05	
g _m [‡]	Transconductance of integrator	Charge mode	R _L = 1 kΩ from Source to Sink, V _(CAP) = V _{EE} to V _{T+} - 0.1 V	3		μS	
		Discharge mode	I _O (SRC) = -10 mA, I _O (SNK) = 10 mA, V _{CAP} = V _{T+} + 0.1 V to V _{T-} + 0.1 V	3			

[†] All typical values are at V_{CC} = 20 V, V_{EE} = -20 V, T_J = 25°C.

[‡] Transconductance (g_m) of the integrator is: I_(CAP)/[V_(SRC) - V_(SNK)]. The ratio of V_{T+} / V_I(TC) is factory adjusted to compensate for variances in g_m. This causes the integration time to be more constant from unit to unit.

NOTES: 6. These parameters must be measured on one output at a time using pulse techniques, t_w = 1 ms, duty cycle < 10%.

7. Threshold values are those voltage levels at the CAP terminal at which the source output changes state. A level more positive than V_{T+} causes the source output to go to the off state, and a level more negative than V_{T-} causes the source output to go to the on state. Both V_{T+} and V_{T-} are variable values that are dependent on the voltage level at the TC input.

8. V_{T+} and V_{T-} are measured differentially with CAP terminal voltage referenced to the V_{EE} terminal.

9. Both V_{T+} and V_{T-} must be measured at the same junction temperature using the same TC voltage.

PARAMETER MEASUREMENT INFORMATION

NOTES: A. The pulse generator has the following characteristics: PRR \leq 5 kHz, $t_w = 10\ \mu\text{s}$, $Z_0 = 50\ \Omega$.
B. C_L includes probe and jig capacitance.

FIGURE 1. SWITCHING TIMES FROM A INPUTS

TYPICAL APPLICATION DATA

A typical application of the SN75608 Dual Flux-Regulating Actuator driving inductive loads is shown in Figure 2. Figure 3 illustrates representative waveforms that occur with the circuit connected as shown in Figure 2. The waveforms illustrate adjustment of output current in the load to compensate for a change in the load inductance while maintaining a constant CAP voltage waveform and thus constant electromagnetic flux in the load.

For optimum operation, both V_{CC} pins must be connected together, close to the package, as well as all three V_{EE} pins. A low-impedance bypass capacitor, 10 microfarads or larger, should be connected between V_{CC} and V_{EE} , also close to the package. The value of the integration capacitor connected between the CAP terminal and V_{EE} is dependent on the load characteristics and the performance desired. The analog voltage on the TC terminal may be varied between 2 volts and 6 volts for fine adjustment of integrator timing characteristics.

description

The SN75609 is a high-current dual flux-regulating actuator designed for switching double-ended loads with currents up to 2.5 amperes at supply voltages from 30 volts to 60 volts. It is designed to drive and control the electromagnetic flux in printheads, solenoids, relays, and other loads whose inductance value varies during operation.

The SN75609 performs the function of flux regulation under control of standard TTL or CMOS input signals for two independent channels. Flux is proportional to the integral of the inductive-load voltage. It is a function of the total amount of current in the load and is the magnetic field maintained in the load. With flux regulation, the load current will vary to compensate for core saturation, temperature changes, and other variations of load inductance during operation while maintaining controlled, relatively constant flux in the load.

Each channel has separate sink and source driver outputs for driving each end of the inductive load. Internal feedback, consisting of an integrator and voltage comparator, provides flux regulation via chop-mode operation of the source output. The integrator circuit provides current to the capacitor terminal (CAP) proportional to the differential voltage between the sink and source outputs for each channel. The integrator requires an external capacitor connected between the CAP and GND terminals. The voltage at the CAP terminal, referenced to GND, is proportional to the integral of the source-to-sink (load) voltage.

The feedback path is completed by a differential voltage comparator that controls the state of the source output. The inverting comparator input is connected to the CAP terminal, and the noninverting input is connected to an analog voltage, $V_{ref}(TC)$, which is referenced to GND. $V_{ref}(TC)$ is proportional to the Threshold Control (TC) voltage, which is referenced to ground. The comparator hysteresis controls the charge and discharge voltage excursions at the CAP terminal and thus controls the on and off time of the source output chopper.

description (continued)

The SN75609 features built-in thermal protection and a sink output over-current sensor to prevent damage to the device. The outputs are disabled under low-V_{CC} supply-voltage conditions to prevent transient output turn-on during power-up or power-down. The TC input is a combined threshold and logic input that disables the outputs when the TC input voltage is less than 0.8 V. This permits an external RC time delay at the TC input during logic system power-up to allow logic at input A to stabilize without causing undesired output turn-on. When a fault condition is detected by any one of these four protection features, the RS latch for each channel is set. The fault condition must be removed and the A input taken high before the RS latch will reset, reactivating the channel.

The SN75609 is characterized for operation from -20°C to 85°C.

DRIVER FUNCTION TABLE (EACH CHANNEL)

A	INPUTS		OUTPUTS		OPERATING MODE	COMMENTS
	TC	CAP	SOURCE	SINK		
X	≤0.8 V	X	OFF	OFF	Disabled	TC acts as a digital input referenced to GND
H	≥2 V	X	OFF	OFF	Active	TC acts as an analog input referenced to GND (See Note 1)
L	≥2 V	<V _{T+}	ON	ON		
L	≥2 V	>V _{T-}	OFF	ON		

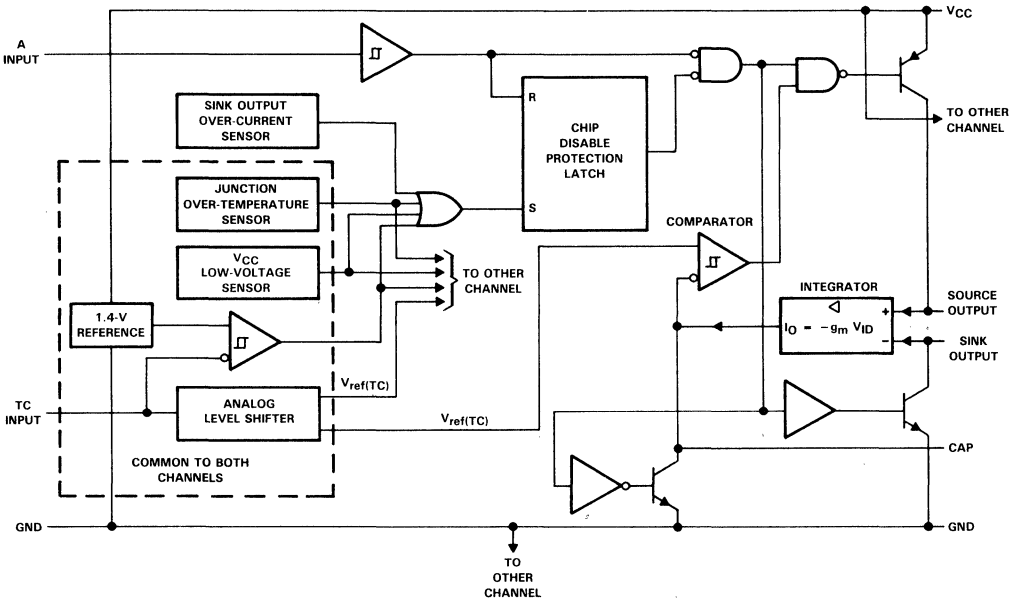

INTEGRATOR FUNCTION TABLE (EACH CHANNEL)

I_{IL}	Low-level input current at A	$V_I = 0$				-10	μA
I_I	Input current at TC	$V_I = 0$ to 6 V				± 10	μA
$I_{I(CAP)}$	Current at CAP terminal	Reset mode	$V_{I(CAP)} = 1 \text{ V}$ to 6 V		1	4	μA
		Charge mode	$V_I(\text{TC}) = 5 \text{ V}$, $V_{I(CAP)} = 2 \text{ V}$, $R_L = 1 \text{ k}\Omega$ from Source to Sink		-115		
		Discharge mode	$V_I(\text{TC}) = 2 \text{ V}$, $V_{I(CAP)} = 5 \text{ V}$, $I_{O(SRC)} = -10 \text{ mA}$, $I_{O(SNK)} = 10 \text{ mA}$		5		
V_{T+}	Positive-going threshold voltage at CAP terminal (charge mode)	$R_L = 1 \text{ k}\Omega$ from Source to Sink, $V_I(\text{TC}) = 3 \text{ V}$ to 6 V	See Notes 7 and 8	$V_I(\text{TC})$			
V_{T-}	Negative-going threshold voltage at CAP terminal (discharge mode)			$0.95 V_I(\text{TC})$			
V_{hys}	Normalized hysteresis at CAP terminal $[(V_{T+} - V_{T-})/V_{T+}]$			See Notes 7, 8, and 9		0.05	
g_m^{\ddagger}	Transconductance of integrator	Charge mode	$R_L = 1 \text{ k}\Omega$ from Source to Sink, $V_{I(CAP)} = 0 \text{ V}$ to $V_{T+} - 0.1 \text{ V}$		3		μS
		Discharge mode	$I_{O(SRC)} = -10 \text{ mA}$, $I_{O(SNK)} = 10 \text{ mA}$, $V_{CAP} = V_{T+} + 0.1 \text{ V}$ to $V_{T-} + 0.1 \text{ V}$		3.		

[†] All typical values are at $V_{CC} = 40 \text{ V}$, $T_A = 25^\circ\text{C}$.

[‡] Transconductance (g_m) of the integrator is: $I_{I(CAP)}/[V_{I(SRC)} - V_{I(SNK)}]$. The ratio of $V_{T+}/V_I(\text{TC})$ is factory adjusted to compensate for variances in g_m . This causes the integration time to be more constant from unit to unit.

NOTES: 6. These parameters must be measured on one output at a time using pulse techniques, $t_W = 1 \text{ ms}$, duty cycle $< 10\%$.

7. Threshold values are those voltage levels at the CAP terminal at which the source output changes state. A level more positive than V_{T+} causes the source output to go to the off state, and a level more negative than V_{T-} causes the source output to go to the on state. Both V_{T+} and V_{T-} are variable values that are dependent on the voltage level at the TC input.

8. V_{T+} and V_{T-} are measured differentially with CAP terminal voltage referenced to the GND terminal.

9. Both V_{T+} and V_{T-} must be measured at the same junction temperature using the same TC voltage.

TYPICAL APPLICATION DATA

A typical application of the SN75609 Dual Flux-Regulating Actuator driving inductive loads is shown in Figure 2. Figure 3 illustrates representative waveforms that occur with the circuit connected as shown in Figure 2. The waveforms illustrate adjustment of output current in the load to compensate for a change in the load inductance while maintaining a constant CAP voltage waveform and thus constant electromagnetic flux in the load.

For optimum operation, both V_{CC} pins must be connected together, close to the package, as well as all three GND pins. A low-impedance bypass capacitor, 10 microfarads or larger, should be connected between V_{CC} and GND, also close to the package. The value of the integration capacitor connected between the CAP terminal and GND is dependent on the load characteristics and the performance desired. The analog voltage on the TC terminal may be varied between 3 volts and 6 volts for fine adjustment of integrator timing characteristics.

description

The SN754410 is a quadruple high-current half-H driver designed to provide bidirectional drive currents of up to one ampere at voltages from 4.5 volts to 36 volts. It is designed to drive inductive loads such as relays, solenoids, dc and stepping motors, as well as other high-current/high-voltage loads in positive-supply applications.

All inputs are compatible with TTL and low-level CMOS logic. Each output (Y) is a complete totem-pole driver with a Darlington transistor sink and a psuedo-Darlington source. Channels are enabled in pairs with channels 1 and 2 enabled by 1,2EN and channels 3 and 4 enabled by 3,4EN. When an enable input is high, the associated channels are enabled and their outputs become active and in phase with their inputs. When the enable input is low, those channels are disabled and their outputs are off and in a high-impedance state. With the proper data inputs, each pair of drivers form a full-H (or bridge) reversible drive suitable for solenoid or motor applications.

A separate supply voltage (VCC1) is provided for the logic input circuits to minimize device power dissipation. Supply voltage (VCC2) is used for the output circuits.

The SN754410 is designed for operation from -40°C to 85°C.

description

The TL376C is a monolithic bipolar three-channel stepper-motor driver. The input signal is inverted through the device and drives a totem-pole output section. Each output can source or sink up to 500 milliamperes. The wide supply-voltage range coupled with a threshold voltage level of approximately one-half V_{CC} allows this device to interface with MOS as well as bipolar outputs. An active-pull-down circuit is included on each input. In typical operation, a microprocessor supplies a three-phase signal to the device, which then drives a two-winding stepper-motor.

The TL376C is characterized for operation from 0°C to 70°C.

description

These quadruple Darlington switches are monolithic bipolar devices especially designed for high-current, high-voltage peripheral driver applications. The devices are designed to offer solutions to interface problems involving electronic-discharge printers, bipolar and unipolar dc motor drivers, telephone relays, LEDs, PIN diodes, and other high-current loads operating from negative power supplies.

The UDN2841 is intended for current-sink applications with the load connected to ground and the device switching the negative supply. The UDN2845 is a sink and source combination for use in bipolar switching applications where both ends of the load are floating. The UDN2841 and UDN2845 each feature inputs that are compatible with standard TTL and 5-volt CMOS signals. The p-n-p input transistor serves as a level translator and the first n-p-n transistor stage is designed to provide sufficient current gain to drive the output Darlington-connected pair.

Driver channels 2 and 4 have uncommitted collectors and emitters while 1 and 3 have emitters internally connected to the substrate. For proper operation, the substrate must be connected to the most-negative supply voltage.

The UDN2841 and UDN2845 are characterized for operation from -20°C to 85°C .

HIGH-VOLTAGE HIGH-CURRENT DARLINGTON TRANSISTOR ARRAYS

- 500 mA Rated Collector Current (Single Output)
- High-Voltage Outputs . . . 50 V
- Output Clamp Diodes
- Inputs Compatible with Various Types of Logic
- Relay Driver Applications
- Designed to be Interchangeable with Sprague ULN2001A Series

D OR N PACKAGE
(TOP VIEW)

description

The ULN2001A, ULN2002A, ULN2003A, ULN2004A, and ULN2005A are monolithic high-voltage, high-current Darlington transistor arrays. Each consists of seven n-p-n Darlington pairs that feature high-voltage outputs with common-cathode clamp diodes for switching inductive loads. The collector-current rating of a single Darlington pair is 500 milliamperes. The Darlington pairs may be paralleled for higher current capability. Applications include relay drivers, hammer drivers, lamp drivers, display drivers (LED and gas discharge), line drivers, and logic buffers. For 100-volt (otherwise interchangeable) versions, see the SN75465 through SN75469.

The ULN2001A is a general-purpose array and may be used with TTL, P-MOS, CMOS, and other MOS technologies. The ULN2002A is specifically designed for use with 14- to 25-volt P-MOS devices and each input has a zener diode and resistor in series to limit the input current to a safe limit. The ULN2003A has a 2700-ohm series base resistor for each Darlington pair for operation directly with TTL or 5-volt CMOS. The ULN2004A has a 10.5-kilohm series base resistor to allow its operation directly from CMOS or P-MOS that use supply voltages of 6 to 15 volts. The required input current is below that of the ULN2003A and the required voltage is less than that required by the ULN2002A. The ULN2005A has a 1050-ohm series base resistor and is especially designed for use with TTL where higher output current is required and loading of the driving source is not a concern.

description

The ULN2068 and ULN2069 are monolithic integrated circuits each consisting of four high-voltage, high-current n-p-n cascaded transistor switches. Each switch includes a first stage compatible with both TTL and 5-volt CMOS signal levels. The second and third stages form uncommitted-collector outputs with common-cathode clamp diodes for switching inductive loads.

The ULN2068 and ULN2069 can sink up to 1.5 amperes per switch. Applications include logic buffers, MOS drivers, memory drivers, line drivers, relay drivers, hammer drivers, lamp drivers, and display drivers (LED and gas discharge).

The ULN2068 and ULN2069 are characterized for operation from -20°C to 85°C .

- Output Collector Current . . . 1.5 A Max
- 2-W Dissipation Rating
- High Output-Voltage Capability
- Output Sink- or Source-Current Capabilities
- Input Compatible with TTL or 5-V CMOS
- Designed for Interchangeability with Sprague ULN2074 and ULN2075

description

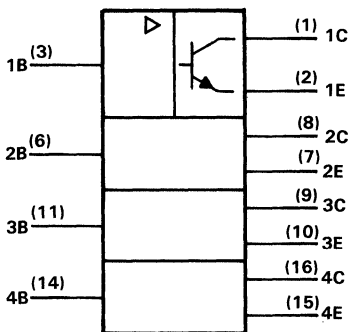

The ULN2074 and ULN2075 are monolithic, quadruple, high-voltage, high-current n-p-n darlington-transistor amplifier devices. They feature high-voltage outputs with collector-current ratings of 1.5 amperes for each darlington pair.

The ULN2074 and ULN2075 are unique general-purpose devices, each featuring uncommitted collectors and emitters to allow for either sinking or sourcing the output current. These devices offer the system designer the flexibility of tailoring the circuit to the application. Typical applications include logic buffers, relay drivers, lamp drivers, and hammer drivers.

For proper operation, the substrate must be connected to the most negative voltage.

The ULN2074 and ULN2075 are characterized for operation from -20°C to 85°C .

positive logic: $Y = \overline{G}_Y + A \cdot S_A + B \cdot S_B$

$Z = \overline{G}_Z + \overline{Y}$

$Z = \overline{G}_Z + G_Y(\overline{A} + \overline{S}_A) (\overline{B} + \overline{S}_B)$

DEFINITION OF LOGIC LEVELS

INPUT	H	L	X
A or B [†]	$V_{ID} \geq V_T \text{ max}$	$V_{ID} \leq V_T \text{ min}$	Irrelevant
Any G or S	$V_I \geq V_{IH} \text{ min}$	$V_I \leq V_{IL} \text{ max}$	Irrelevant

[†]A and B are differential voltages (V_{ID}) between A1 and A2 or B1 and B2, respectively. For these circuits, V_{ID} is considered positive regardless of which terminal of each pair is positive with respect to the other.

description

The SN5520 monolithic sense amplifier is designed for use with high-speed memory systems. This sense amplifier detects bipolar differential-input signals from the memory and provides the necessary interface circuitry between the memory and the logic section. Low-level pulses originating in the memory are transformed into logic levels compatible with standard TTL circuits.

The SN5520 sense amplifier features multiple differential-input preamplifiers and versatile gating and output circuits, permitting a significant reduction in the circuitry required to accomplish the sensing function. A unique circuit design provides an inherent stability of the input threshold level over a wide range of supply voltage levels and temperature ranges. Independent strobing of each of the dual sense-input channels ensures maximum versatility and permits detection to occur when the signal-to-noise ratio is at a maximum. The gate and strobe inputs and the outputs are compatible with standard TTL logic circuits.

With the Z output connected to the G_Y input, the SN5520 may be used to perform the functions of a flip-flop or register that responds to the sense and strobe input conditions.

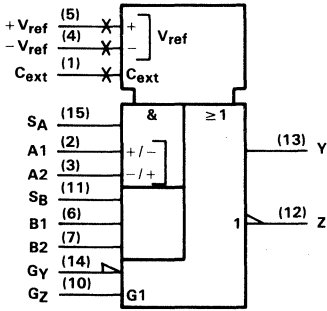

The SN5520 is available in the J ceramic dual-in-line package and is characterized for operation over the full military temperature range of -55°C to 125°C.

SN5520 DUAL-CHANNEL SENSE AMPLIFIER WITH COMPLEMENTARY OUTPUTS

circuit operation

The SN5520 is a dual-channel sense amplifier with the preamplifiers connected to a common output stage and a complementary output stage. The output circuit is composed of two cascaded NAND gates, each with external gate inputs. External connection of the Z output and the G_Y input results in a flip-flop or register that is set by signals at the differential-input terminals. Reset of the register is performed by taking the G_Z input low. Capacitive coupling from output Z to G_Y results in output pulse stretching. With either connection, complementary output levels are available. The gate and strobe inputs and the outputs are compatible with standard TTL logic. The input function of the SN5520 can be expanded by connecting the Y output of the SN5522 to the G_Y input of the circuit being expanded.

TYPICAL APPLICATIONS

large memory systems

This application demonstrates an improved method of sensing data from large memory systems. The signal-to-noise ratio can be increased by sectioning the large core planes as illustrated in Figure 16. Two segments, usually consisting of 4096 cores each, can be interfaced by each of the dual-input channels of the SN5520 or SN5522 sense amplifiers. The cascaded output gates of the SN5520 circuits may be connected to serve as the memory data register (MDR). A number of SN5522 sense amplifiers may be wire-AND connected to expand the input function of the MDR to interface all the segments of the plane. Complementary outputs, clear, and preset functions are provided for the MDR. Rules for combined fan-out and wire-AND capabilities must be observed.

description

The SN5522 monolithic sense amplifier is designed for use with high-speed memory systems. This sense amplifier detects bipolar differential-input signals from the memory and provides the necessary interface circuitry between the memory and the logic section. Low-level pulses originating in the memory are transformed into logic levels compatible with standard TTL circuits.

The SN5522 sense amplifier features multiple differential-input preamplifiers and versatile gating and output circuits, permitting a significant reduction in the circuitry required to accomplish the sensing function. A unique circuit design provides an inherent stability of the input threshold level over a wide range of supply voltage levels and temperature ranges.

Independent strobing of each of the dual sense-input channels ensures maximum versatility and permits detection to occur when the signal-to-noise ratio is at a maximum. The gate and strobe inputs and the outputs are compatible with standard TTL logic circuits.

The circuit features a high-fanout, single-ended, open-collector output stage. In addition, it may be used to expand the inputs to a SN5520 circuit or to perform the wire-AND function.

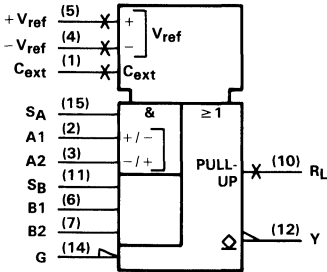

The SN5522 is available in the J ceramic dual-in-line package and is characterized for operation over the full military temperature range of -55°C to 125°C .

SN5522 DUAL-CHANNEL SENSE AMPLIFIER WITH OPEN-COLLECTOR OUTPUTS

circuit operation

The SN5522 is a dual-channel sense amplifier with the preamplifiers connected to a common output stage. The output circuit features an open-collector output that permits two or more of these outputs to be connected in the wire-AND configuration. Each package includes a load resistor that may be used as the output pullup resistor. High sink-current capability is a feature of this design, and a separate ground terminal is used for the output circuitry. This device can also be used as an input expander for the SN5520 circuit.

SN5522

DUAL-CHANNEL SENSE AMPLIFIER WITH OPEN-COLLECTOR OUTPUTS

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC+} (see Note 1)	7 V
Supply voltage, V_{CC-}	-7 V
Differential input voltage, V_{ID} or V_{ref}	± 5 V
Voltage from any input to ground (see Note 2)	5.5 V
Off-state voltage applied to open-collector outputs	5.5 V
Continuous total power dissipation at (or below) 25°C free-air temperature (see Note 3)	1375 mW
Operating free-air temperature range	-55°C to 125°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds	300°C

- NOTES: 1. Voltage values, except differential voltages, are with respect to the network ground terminal.
 2. Strobe and gate input voltages must be zero or positive with respect to the network ground terminal.
 3. For operating above 25°C free-air temperature, derate total power linearly at the rate of 11.0 mW/°C.

recommended operating conditions

	MIN	NOM	MAX	UNIT
Positive supply voltage, V_{CC+}	4.75	5	5.25	V
Negative supply voltage, V_{CC-}	-4.75	-5	-5.25	V
Reference voltage, V_{ref}	15		40	mV
High-level input voltage (strobe and gate inputs), V_{IH}		2		V
Low-level input voltage (strobe and gate inputs), V_{IL}			0.8	V

electrical characteristics over recommended operating free-air temperature range, $V_{CC\pm} = \pm 5$ V, R_L connected to output, (unless otherwise noted)

- NOTES: 5. Differential-input overload recovery time is the time necessary for the device to recover from the specified differential-input overload signal prior to the strobe-enable signal.
6. Common-mode-input overload recovery time is the time necessary for the device to recover from the specified common-mode-input overload signal prior to the strobe-enable signal.

driving SN54XXX loads and combining outputs

The table below provides minimum and maximum resistor values for driving one to ten SN54XXX loads and wire-AND connecting two to seven parallel outputs. Each value shown for one wire-AND output is determined by the fanout plus the cutoff current of a single output transistor. Extension beyond seven wire-AND connections is permitted with fanouts of seven or less if a valid minimum and maximum R_L is possible. When fanning out to ten SN54XXX loads, the calculation for the minimum value of R_L indicates that an infinite resistance should be used; however, the use of a 4-k Ω resistor in this case will satisfy the high-level condition and limit the low level to less than 0.43 volt.

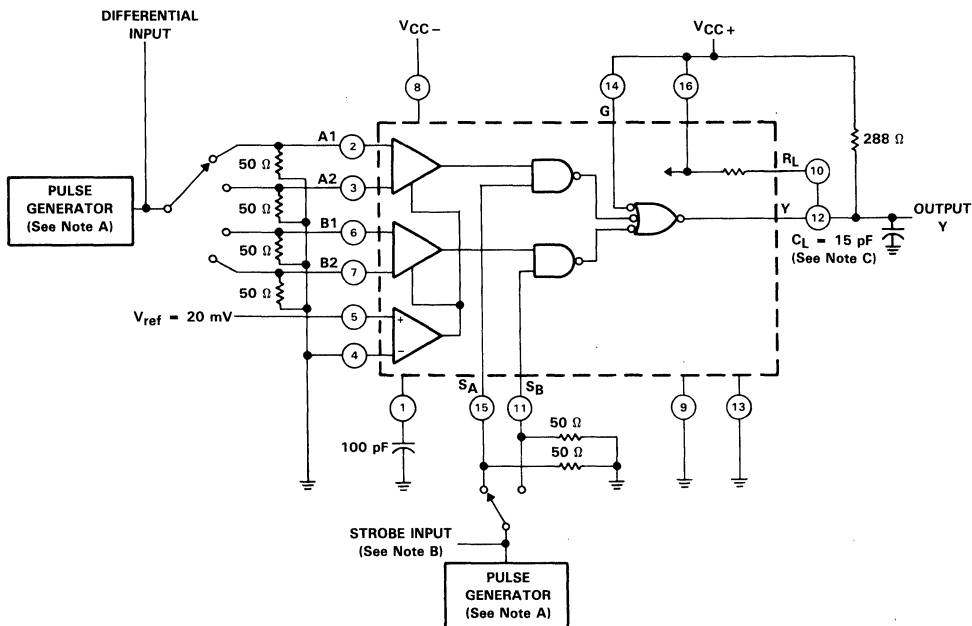

FANOUT TO TTL LOADS	WIRE-AND OUTPUTS							
	1	2	3	4	5	6	7	1 to 7
1	8965	4814	3291	2500	2015	1688	1452	319

APPLICATION DATA

large memory systems

This application demonstrates an improved method of sensing data from large memory systems. The signal-to-noise ratio can be increased by sectioning the large core planes as illustrated in Figure 14. Two segments, usually consisting of 4096 cores each, can be interfaced by each of the dual-input channels of the SN5520 or SN5522 sense amplifiers. The cascaded output gates of the SN5520 circuits may be connected to serve as the memory data register (MDR). A number of SN5522 sense amplifiers may be wire-AND connected to expand the input function of the MDR to interface all the segments of the plane. Complementary outputs, clear, and preset functions are provided for the MDR. Rules for combined fan-out and wire-AND capabilities must be observed.

- Plug-in Configuration Ideal for Flow-Soldering Techniques

description

The SN5524 monolithic sense amplifier is designed for use with high-speed memory systems. This sense amplifier detects bipolar differential-input signals from the memory and provides the necessary interface circuitry between the memory and the logic section. Low-level pulses originating in the memory are transformed into logic levels compatible with standard TTL circuits.

The SN5524 sense amplifier features multiple differential-input preamplifiers and versatile gating and output circuits, permitting a significant reduction in the circuitry required to accomplish the sensing function. A unique circuit design provides an inherent stability of the input threshold level over a wide range of supply voltage levels and temperature ranges. Independent strobing of each of the dual sense-input channels ensures maximum versatility and permits detection to occur when the signal-to-noise ratio is at a maximum. The strobe inputs and the outputs are compatible with standard TTL logic circuits.

The circuit provides for independent, dual-channel sensing with separate outputs.

The SN5524 is available in the J ceramic dual-in-line package and is characterized for operation over the full military temperature range of -55°C to 125°C .

S	$V_I \geq V_{IH} \text{ min}$	$V_I \leq V_{IL} \text{ max}$	Irrelevant

$^{\dagger}A$ is a differential voltage (V_{ID}) between A1 and A2. For these circuits, V_{ID} is considered positive regardless of which terminal is positive with respect to the other.

SN55234 DUAL SENSE AMPLIFIER

circuit operation

The SN55234 dual sense amplifier circuit features two completely independent sense amplifiers in a single package. Each amplifier features high fanout capability. An additional stage in the output gate provides an inverted output and internal compensation has been added. By not using a separate gate for inversion, the package count is reduced and less propagation delay is added. The need for an external roll-off capacitor is also eliminated.

Memory Interface Circuits

TYPICAL APPLICATIONS

small memory systems

This application demonstrates an improved method of sensing data from small memory systems. Two individual core planes, usually consisting of 4096 cores each, can be interfaced by each of the dual-channel SN55234 sense amplifiers, see Figure 13. Standard TTL integrated circuits, driven from the compatible sense-amplifier outputs, may be selected to serve as the memory data register (MDR).

SN55325 MEMORY CORE DRIVER

D969, MARCH 1971—REVISED SEPTEMBER 1986

- 600-mA Output Capability
- Fast Switching Times
- Output Transient-Voltage Protection
- Dual Sink and Dual Source Outputs
- Minimum Time Skew Between Address and Output Current Rise
- 24-Volt Output Capability
- Source Base Drive Externally Adjustable
- TTL Compatibility
- Input Clamping Diodes
- Transformer Coupling Eliminated
- Reliability Increased
- Drive-Line Lengths Reduced
- Use of External Components Minimized

description

The SN55325 monolithic integrated circuit memory driver is designed for use with magnetic memories.

The device contains two 600-milliampere source switches and two 600-milliampere sink switches. Source selection is determined by one of two logic inputs, and source turn-on is determined by the source strobe. Likewise, sink selection is determined by one of two logic inputs, and sink turn-on is determined by the sink strobe. This arrangement allows selection of one of the four switches and its subsequent turn-on with minimum time skew of the output current rise.

When R_{int} and node R are connected together, the amount of base drive available for the source-1 or source-2 output transistor is set internally by a 575-ohm resistor. This method provides adequate base drive for source currents up to 375 mA with a V_{CC2} voltage of 15 volts or 600 mA with a V_{CC2} voltage of 24 volts.

When source currents greater than 375 mA are required, it is recommended that a resistor of the appropriate value be connected between V_{CC2} and node R and R_{int} must remain open. By using this method the source base current may usually be regulated within $\pm 5\%$. An advantage of this method of setting the base drive is that the power dissipated by this resistor is external to the package and allows the integrated circuit to operate at higher source currents for a given junction temperature.

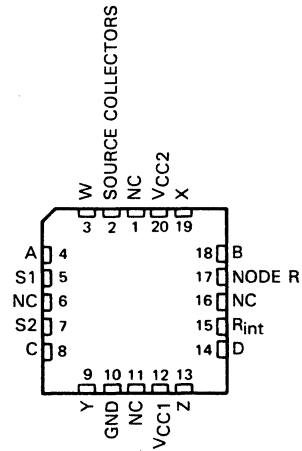

Each sink-output collector has an internal pull-up resistor in parallel with a clamping diode connected to V_{CC2} . This arrangement provides protection from voltage surges associated with switching inductive loads.

The SN55325 is characterized for operation over the full military temperature range of -55°C to 125°C .

schematic

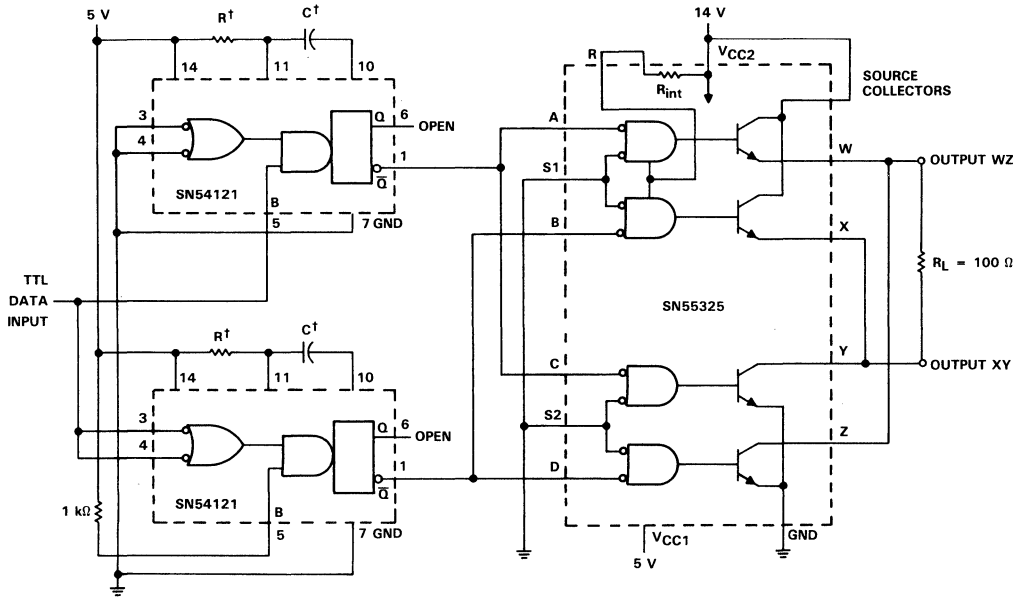

Component values shown are nominal. Pin numbers shown are for the J package.

TYPICAL APPLICATION DATA

balanced bipolar logic-line driver

The circuit shown in Figure 1 converts standard TTL logic to bipolar logic. Bipolar logic is primarily used in transmitting data or clock pulses over long lines. This line-driver may be operated from a single 5-volt supply; however, the output drive may be increased by raising the supply voltage to the source collectors. The circuit features a three-state output that is off during the absence of data, thus not dissipating high power. It provides a balanced drive circuit giving maximum noise immunity when used with the proper line receiver. Large drive levels can be used to further increase noise immunity. The circuit is capable of driving twisted-pair lines of several thousand feet in length or low-impedance coaxial lines.

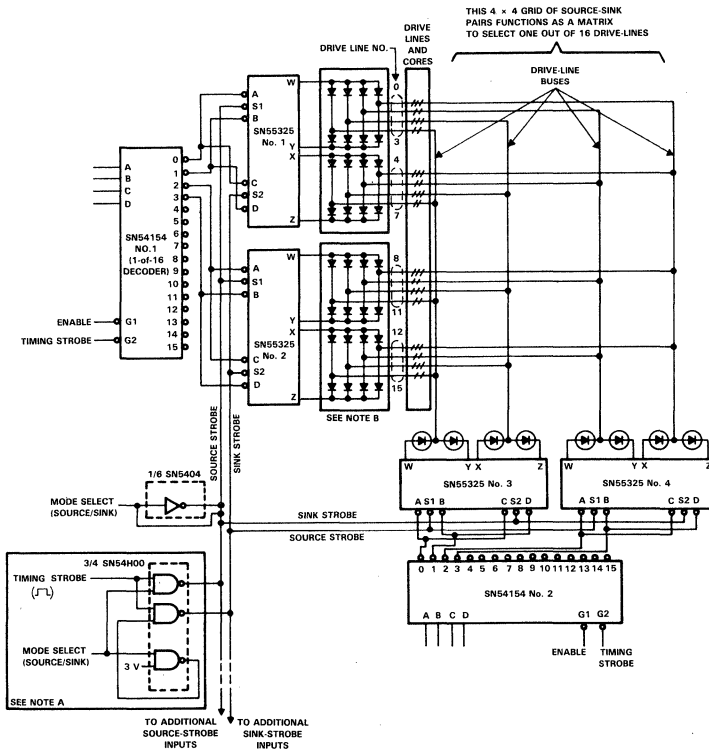

†R and C are adjusted to give the desired bipolar output pulse width.

FIGURE 1. BALANCED BIPOLAR LOGIC-LINE DRIVER

TYPICAL APPLICATION DATA

balanced bipolar logic-line driver

In memory-drive applications, the SN55325 can be connected in any of several ways. Typically, however, sources and sinks are arranged in pairs from which many drive-lines branch off as shown in Figure 2. Here each drive-line is served by a unique combination of two source/sink pairs so that a selection matrix is formed. To select drive-line 13, SN54154 No. 1 must be set to 3 (with mode select high), enabling source X of SN55325 No. 2 to drive lines 12 through 15, and SN54154 No. 2 must be set to 2, providing a sink at Y of SN55325 No. 4 for drive-line 13 only. Alternatively, to drive current in drive-line 13 in the opposite direction, only the mode-select voltage would be changed from high to low. The size of such a matrix is limited only by the number of drive-lines that a source/sink pair can serve. This number in turn depends on the capacitive and inductive load that each drive-line of the particular system imposes on the driver. A 256-drive-line selection matrix is shown in Figure 3. These 256 drive-lines are sufficient to serve $(256/2)^2 = 16,384$ individual cores.

- NOTE** A: This optional mode-select and timing-strobe technique can be used in place of the SN5404 mode-select and SN54154 timing-strobe when minimum time skew is desired.
 B: All diodes are IN4607.

FIGURE 2. SN55325 USED AS A MEMORY DRIVER TO SELECT ONE OF SIXTEEN DRIVE LINES

TYPICAL APPLICATION DATA

external resistor calculation

A typical magnetic-memory word-drive requirement is shown in Figure 4. A source-output transistor of one SN55325 delivers load current (I_L). The sink-output transistor of another SN55325 sinks this current.

The value of the external pull-up resistor (R_{ext}) for a particular memory application may be determined using the following equation:

$$R_{ext} = \frac{16 [V_{CC2(min)} - V_S - 2.2]}{I_L - 1.6 [V_{CC2(min)} - V_S - 2.9]} \quad (1)$$

where: R_{ext} is in $k\Omega$,

$V_{CC2(min)}$ is the lowest expected value of V_{CC2} in volts,

V_S is the source output voltage in volts with respect to ground,

I_L is in mA.

The power dissipated in resistor R_{ext} during the load current pulse duration is calculated using Equation 2,

$$P_{R_{ext}} \approx \frac{I_L}{16} [V_{CC2(min)} - V_S - 2] \quad (2)$$

where: $P_{R_{ext}}$ is in mW.

After solving for R_{ext} , the magnitude of the source collector current (I_{CS}) is determined from Equation 3,

$$I_{CS} \approx 0.94 I_L \quad (3)$$

where: I_{CS} is in mA.

As an example, let $V_{CC2(min)} = 20$ V and $V_L = 3$ V while I_L of 500 mA flows.

Using Equation 1,

$$R_{ext} = \frac{16 (20 - 3 - 2.2)}{500 - 1.6 (20 - 3 - 2.9)} = 0.5 \text{ k}\Omega$$

and from Equation 2,

$$P_{R_{ext}} \approx \frac{500}{16} [20 - 3 - 2] \approx 470 \text{ mW}$$

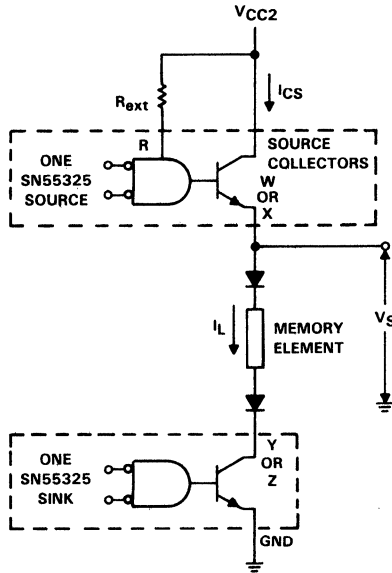

The amount of the memory system current source (I_{CS}) from Equation 3 is:

$$I_{CS} \approx 0.94 (500) \approx 470 \text{ mA}$$

In this example, the regulated source-output transistor base current through the external pull-up resistor (R_{ext}) and the source gate is approximately 30 mA. This current and I_{CS} comprise I_L .

TYPICAL APPLICATION DATA

external resistor calculation (continued)

description

The SN55326 and SN55327 are monolithic integrated circuit quadruple memory core drivers. These devices accept standard TTL decoder input signals and provide high-current and high-voltage output levels suitable for driving magnetic memory elements. Output transistor selection is determined by using one of the four address inputs and the common timing strobe.

The SN55326 memory core driver can sink up to 600 milliamperes and operate from a single 5-volt supply. Each driver is similar to the sink drivers of the SN55325. The four output transistors share a common base-drive resistor and it is recommended that only one of the four driver gates be selected at a time. Output-transistor base current may be increased by connecting an external resistor between R_{ext} (pin 4) and V_{CC} . Each output collector is protected from voltage surges during inductive switching by a clamping diode in parallel with its internal pull-up resistor. The two clamp pins may be returned to a power supply of from 4.5 volts to 24 volts.

The SN55327 memory core switch can source or sink up to 600 milliamperes and operate from two supplies; one of five volts and the other from 4.5 volts to 24 volts. Each switch is similar to the source drivers of the SN55325. They can function as either sink drivers or source drivers since the voltages at the output transistor terminals are capable of swinging between V_{CC2} and ground. The four output transistors share a common base-drive resistor and it is recommended that only one of the four outputs be selected at a time. An internal base-drive resistor is available on the chip and can be used by connecting Node R (pin 4) to R_{int} (pin 5). This resistor provides adequate base current to the output transistors for output sink currents

description (continued)

up to 375 milliamperes with V_{CC2} at 15 volts or 600 milliamperes with V_{CC2} at 24 volts. Base current can be regulated to within ± 5 percent by substituting for this resistor an external resistor connected between Node R (pin 4) and V_{CC2} with R_{int} (pin 5) remaining open. This method is preferable in high-duty-cycle, high-power applications since the power dissipated in this resistor is outside the package. When a source current and V_{CC2} voltage other than the above values are required, it is recommended that the base drive be supplied through an external resistor of the appropriate value calculated using Equation 1 shown in the SN55325 data sheet.

The SN55326 and SN55327 circuits are characterized for operation over the full military temperature range of -55°C to 125°C .

PRODUCT SUMMARY

This data is excerpted from the *TSP50C40A Speech Synthesizer Data Manual* intended for publication in early 1987.

- **LPC-10 Synthesizer**
- **8-Bit Microprocessor**
- **8K-Byte ROM**
- **32-Byte RAM**
- **18 Digital I/O Lines**
- **4-V to 6-V CMOS Technology for Low Power Dissipation**
- **High-Efficiency Push-Pull PWM (Pulse-Width Modulation) Digital-to-Analog Output Can Drive a Speaker Directly**
- **10- or 8-kHz Speech Sample Rate**

**N PACKAGE
(TOP VIEW)**

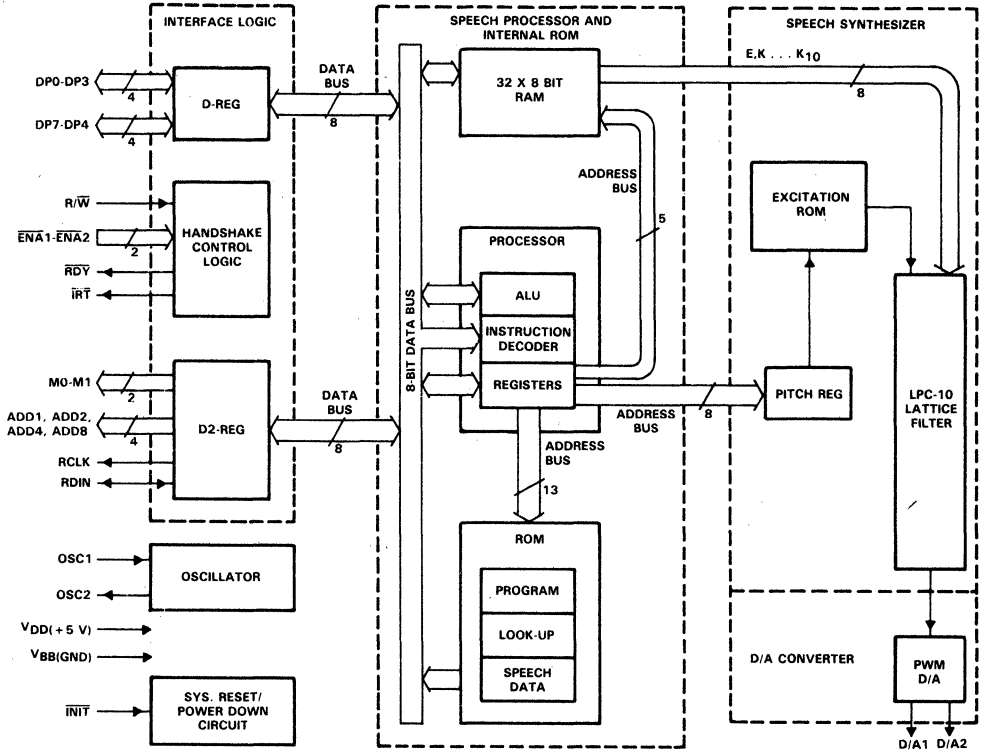

description

The TSP50C40A combines an 8-bit micro-processor, a speech synthesizer, a 32-byte RAM, and a 64K-bit ROM onto one chip.

The TSP50C40A implements an LPC-10 speech synthesis algorithm and a 10-pole lattice filter to generate speech at a low data rate. The TSP50C40A internal processor accesses speech data from an internal and an external ROM (TSP60C20), decodes the speech data, and sends the decoded data to the synthesizer at a predetermined frame data rate. The internal processor also performs interpolations to smooth the transitions between frames. The output of the synthesizer can be used to drive a small speaker directly or can be used with an external low-power filter and amplifier.

The TSP50C40A is characterized for operation from 0°C to 70°C.

functional block diagram

PIN FUNCTION TABLE

PIN		I/O	DESCRIPTION
NAME	NO.		
ADD1	7	O	Address weight 1 output
ADD2	8	O	Address weight 2 output
ADD4	9	O	Address weight 4 output
ADD8	10	O	Address weight 8 output
DPO	19	I/O	Data bit 0 (LSB)
DP1	20	I/O	Data bit 1
DP2	21	I/O	Data bit 2
DP3	22	I/O	Data bit 3
DP4	23	I/O	Data bit 4
DP5	24	I/O	Data bit 5
DP6	25	I/O	Data bit 6
DP7	26	I/O	Data bit 7 (MSB)
D/A1	27	O	Noninverting digital-to-analog converter output (PWM)
D/A2	28	O	Inverting digital-to-analog converter output (PWM)
ENA1	16	I	Input/output control of data bus (DP7–DPO).
ENA2	17	I	Read mode (R/ \bar{W} high) $\bar{E}NA1$: Most significant nibble of data register is sent to the data bus (DP7–DP4) while $\bar{E}NA1$ is low. $\bar{E}NA2$: Least significant nibble of data register is output to the data bus (DP3–DPO) while $\bar{E}NA2$ is low. When $\bar{E}NA1$ goes low, $\bar{I}RT$ goes high. Write mode (R/ \bar{W} low) $E NA1$: Data already set on data bus DP7–DP4 are strobed into most significant nibble of data register toggling $E NA1$ (high-low-high). Data is latched as $E NA1$ goes high. $E NA2$: Data already set on data bus DP3–DPO are strobed into least significant nibble of data register toggling $E NA2$ (high-low-high). Data is latched as $E NA2$ goes high.
$\bar{I}NIT$	4	I	Initialize input. When low, device is initialized and goes into low-power mode.
$\bar{I}RT$	13	O	Ready for data output. $\bar{I}RT$ goes high as data in the data register is read on data bus DP4 through DP7. $\bar{I}RT$ can also be masked programmed to act as an event counter input.
M0	5	O	ROM mode control output
M1	6	O	ROM mode control output
OSC1	2	I	Clock Input
OSC2	3	O	Oscillator output. 2.86 MHz for speech data of 8-kHz sampling and 3.58 MHz for speech data of 10-kHz sampling. Can be used with crystal, ceramic resonator, or external input to OSC2.
RDIN	12	I/O	ROM data input
$\bar{R}DY$	15	O	Ready for data input. $\bar{R}DY$ goes high as data on data bus DPO through DP3 is written into the data register. $\bar{R}DY$ is reset to a low level by internal command.
ROMCLK	11	O	Clock output to a ROM
R/ \bar{W}	18	I	Read/Write input. Determines direction of data bus R/\bar{W} : When high, data transfers from data register (read). R/\bar{W} : When low, data transfers into data register (write).
VDD	1	I	5-volt nominal supply voltage
VSS	14	I	Substrate voltage (ground pin)

absolute maximum ratings over free-air temperature range

Supply voltage [†] , V_{DD}	-0.3 V to 7 V
Input voltage, V_I	-0.3 V to $V_{DD} + 0.3$ V
Output voltage, V_O	-0.3 V to $V_{DD} + 0.3$ V
Storage temperature range	-30°C to 125°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

[†] Unless otherwise noted, all voltages are with respect to V_{SS} .

recommended operating conditions

		$V_{DD} = 5$ V, $V_{OL} = 0.4$ V	1.7	2.4		
		$V_{DD} = 4$ V, $V_{OL} = 0.4$ V	1.2	1.8		
I_{DD}	Supply current	$V_{DD} = 5$ V, $f_{osc} = 3.6$ MHz, All outputs open			2	mA

[‡] All typical values are at $V_{DD} = 5$ V, $T_A = 25$ °C.

PRODUCT SUMMARY

This data is excerpted from the *TSP50C50 Speech Processor Data Manual* intended for publication in early 1987.

- High-Quality Speech
- LPC12 or LPC10 Synthesis Algorithm
- 10-kHz or 8-kHz Sample Rate
- Pitch Accuracy Better Than 0.1% at 1 kHz
- Parameter Interpolation Pitch Synchronous and Asynchronous
- On-Chip A-Law D/A Converter, 13-Bit Dynamic Range
- On-Chip 6th-Order Low-Pass Filter
- Phonetic Coding and Music Capabilities
- Standard 8- or 4-Bit Microprocessor Interface
- Serial Interface to TSP60C20 Speech ROM
- Standard PCM Interface-to-Digital Network
- 4.32 MHz Crystal Oscillator
- 28-Pin Plastic/Ceramic Dual-in-Line Package
- Silicon Gate CMOS Technology
- Single 5-V Power Supply
- Low-Power Standby Mode

J OR N PACKAGE
(TOP VIEW)

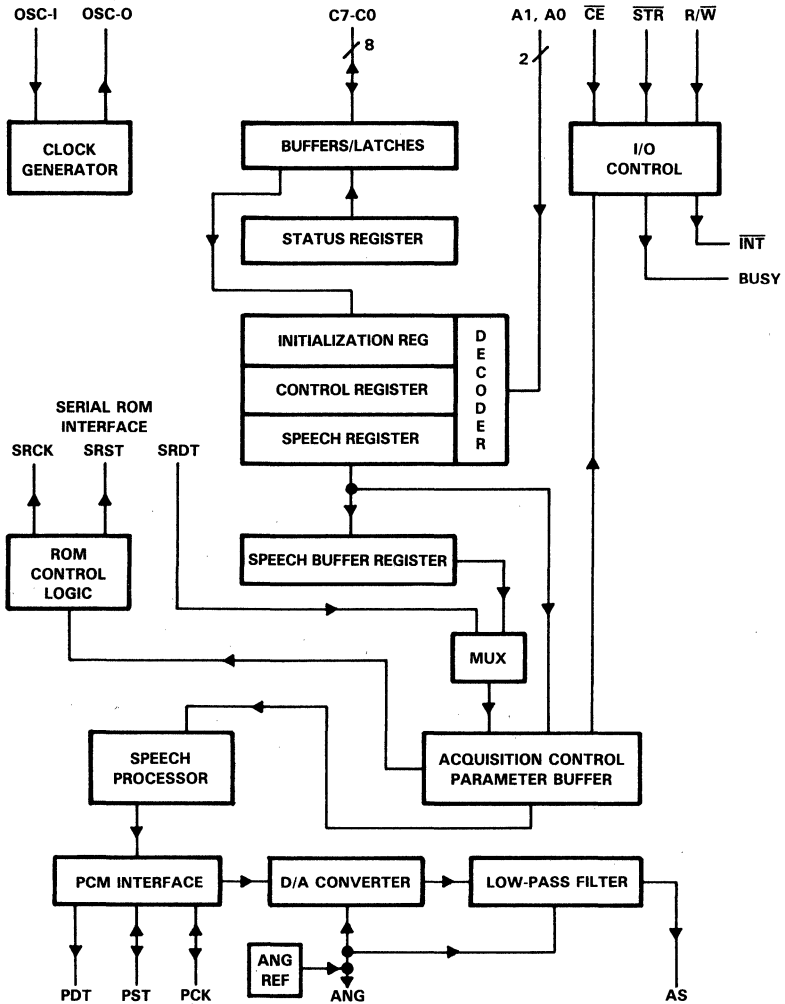

description

The TSP50C50 is a silicon-gate CMOS LSI device consisting of a speech processor, speech acquisition logic, PCM interface logic, analog output circuits, and microprocessor controlled interface. These functional areas contain features and controls that produce band-limited high-quality speech and extends the capability of the TSP50C50 allowing its use with a wide range of speech products. It offers specific controls for constructive speech synthesis and musical and telecommunication network applications.

The TSP50C50 is characterized for operation from 0°C to 70°C.

functional block diagram

PIN FUNCTION TABLE

PIN NAME NO.	I/O	DESCRIPTION
ANG 20		2.5 V analog ground. May be used to polarize an external speaker or to filter parasitic ground noise.
AS 19	O	Analog speech (filtered audio) output. Output is suitable for driving a low-power audio amplifier or a low-power speaker.
A0 4 A1 3	I I	Register address inputs. Used in conjunction with R/\overline{W} to define the function of the registers.
BUSY 25	O	Busy output. When high, indicates that the interface is busy and a write strobe cannot be accepted.
\overline{CE} 2	I	Chip enable input. When high, \overline{CE} disables read and write. When low and strobe is low, \overline{CE} enables read and write.
C0 12 C1 11 C2 10 C3 9 C4 8 C5 7 C6 6 C7 5	I/O I/O I/O I/O I/O I/O I/O	Data input/output
\overline{HC} 27	I	Hardware clear input. When high, disables the low-power standby mode and enables the crystal oscillator. When low, stops the crystal oscillator, sets the register address to nonoperating state, sets the INIT register to the all-high default value, and enables the low-power standby mode.
\overline{INT} 26	O	Interrupt output. When low, indicates that a condition exists in the TSP50C50 that requires immediate action by the microprocessor.
OSC-0 13	O	Oscillator crystal connection
OSC-1 14	I	Oscillator crystal connection or input to TSP50C50 from external oscillator
PCK 22	I/O	Clock input/output. A free-running data-rate clock at 2.16 MHz.
PDT 23	O	Serial PCM/binary two's compliment speech data output
PST 24	I/O	Sample-rate input/output strobe (8 kHz or 10 kHz)
R/\overline{W} 28	I	Read/write select input. When high, selects read status register and, when low, selects write to address register.
SRCK 15	O	720-kHz clock output
SRDT 17	I	External serial speech data input to the multiplexer
SRST 16	O	Single-bit speech data request strobe output to external speech ROM — 360 kHz maximum
\overline{STR} 1	I	Strobe input. When high, disables read and write. When low and \overline{CE} is low, enables read and write.
V_{DD} 18		5-volt power supply
V_{SS} 21		Digital ground

absolute maximum ratings over free-air temperature range (unless otherwise noted)

Supply voltage, V_{DD} (see Note 1)	-0.3 V to 7 V
All input voltages (see Note 1)	-0.3 V to $V_{DD}+0.3$ V
All output voltages (see Note 1)	-0.3 V to $V_{DD}+0.3$ V
Operating free-air temperature range	-55°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

NOTE 1: All voltages are with respect to V_{SS} .

TSP5110A VOICE SYNTHESIS PROCESSOR

D2976, NOVEMBER 1986

PRODUCT SUMMARY

This data is excerpted from the *TSP5110A Voice Synthesis Processor Data Manual* intended for publication in early 1987

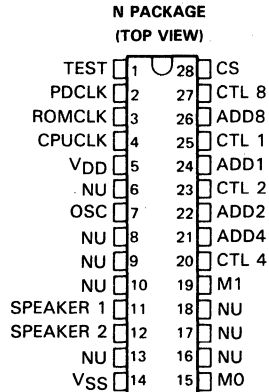

- LPC-10 Pitch Asynchronous Synthesis Algorithm
- On-Chip Oscillator and Clock Generation
- Direct Drive for 50-Ω Speaker
- Simple Control Interface for 4-Bit Microcomputers

description

The TSP5110A is a PMOS Voice Synthesis Processor. Speech is synthesized by processing an externally provided variable data-rate bit stream of encoded speech data and converting the result to an audible output with an on-chip eight-bit digital-to-analog converter and push-pull amplifier. The TSP5110A outputs all control signals necessary for direct control of the TSP6100 vocabulary ROM. Control of the TSP5110A is provided by an external device (e.g., TMS1000) through four control pins and a command clock.

The TSP5110A is characterized for operation from 0°C to 70°C

Speech Synthesis Circuits

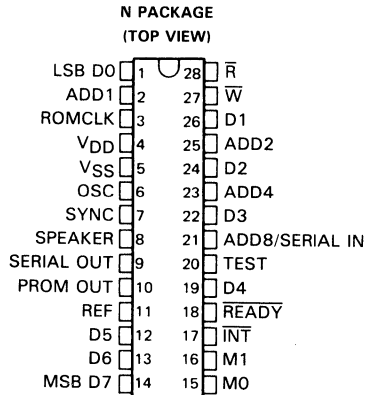

TSP5220C VOICE SYNTHESIS PROCESSOR

D2960, SEPTEMBER 1986

PRODUCT SUMMARY

This data is excerpted from the *TSP5220C Voice Synthesis Processor Data Manual* intended for publication in early 1987

- Pitch-Excited LPC-10 Synthesis Algorithm
- Choice of 4-kHz or 5-kHz Voice Input Bandwidth
- Low Data-Rate Range . . . 1000 to 1700 bps
- On-Chip 8-Bit Digital-to-Analog Converter
- TTL-Compatible Inputs and Outputs
- Compressed Voice Data Input Through Either 8-Bit Control/Data Bus and FIFO for Controller-Supplied Speech Data or Serial Interface for Use with TSP6100 Custom-Masked Speech ROMs

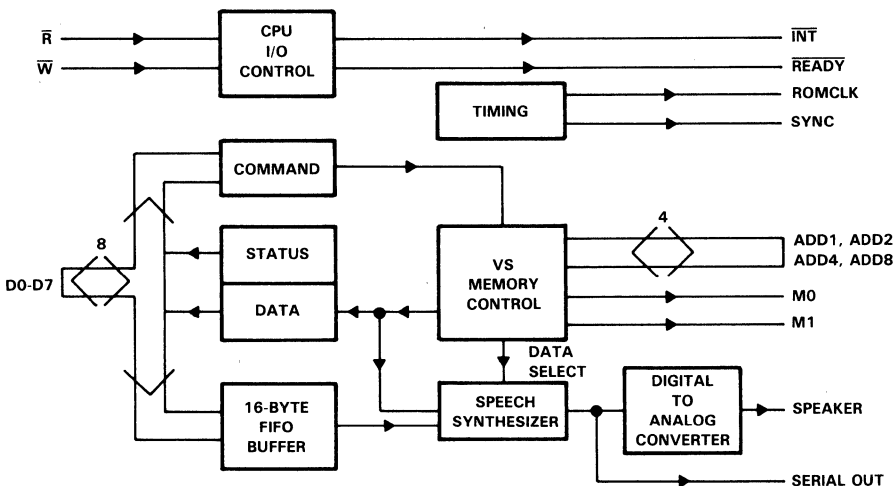

description

The TSP5220C is an LPC-10 voice synthesis function on a chip. A flexible interface structure allows a choice of storage media for the compressed model data and simple microprocessor selection of the spoken phrase or transfer of the data representing that phrase. For best performance, an external low-pass filter should be used between the TSP5220C and the audio amplifier or speaker.

The TSP5220C is characterized for operation from 0°C to 70°C.

functional block diagram

PRODUCTION DATA documents contain information current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

Speech Synthesis Circuits

PRODUCT SUMMARY

This data is excerpted from the *TSP60C20 Read Only Memory Data Manual* intended for publication in early 1987.

- **256K-Bit ROM (Internal Organization
16K × 16K Bits)**
- **On-Chip Address Register with Automatic
Incrementing Feature**
- **Parallel Port (4- or 8-Bit Format, User
Controlled)**
- **Address/Data/Control Compatible with
Memory-Mapped Systems**
- **Serial Port for Interfacing with Speech
Synthesizers or Other Application Requiring
Decoding of Variable Length Codes or Data**
- **Standby Mode for Very Low Power
Consumption**
- **On-Chip Table Lookup of Address (Indirect
Addressing)**
- **TTL and MOS Compatible**

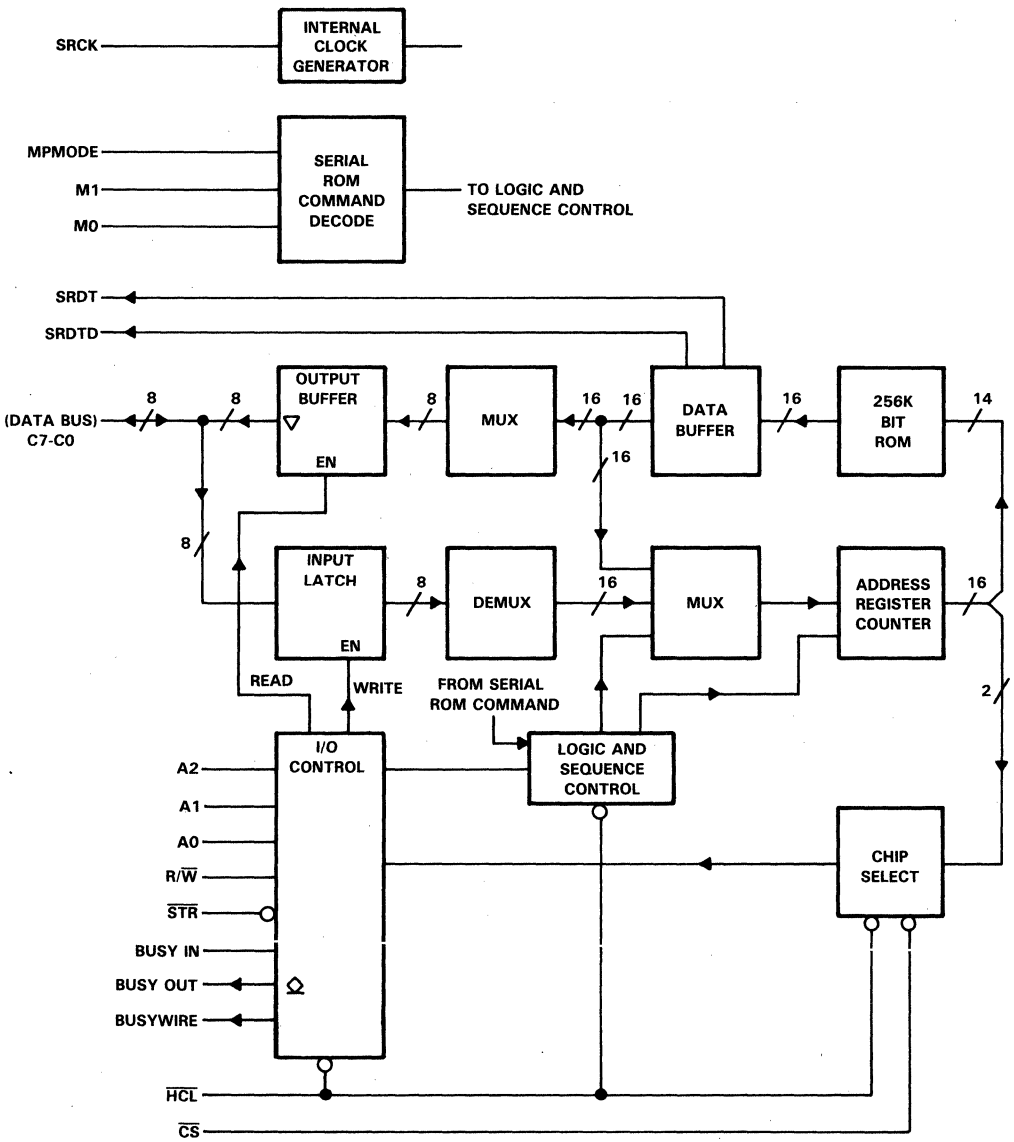

NC—No internal connection

description

The TMS60C20 is a 256K-bit ROM fabricated in CMOS technology for low operating and standby power consumption. The design is optimized for the data storage requirements of synthetic speech systems. Low cost and high density are maximized by increasing access time.

The TMS60C20 is characterized for operation from -40°C to 80°C.

functional block diagram

PIN FUNCTIONAL DESCRIPTION

SRDTD	22	I	Serial data input delayed
SRCK	23	I	Clock input
TEST	27	I	Test enable
V _{DD}	1		5-V power supply
V _{SS}	2		Ground

absolute maximum ratings over free-air temperature range

Supply voltage, V _{DD} (see Note 1)	−0.3 V to 7 V
Input voltage range	−0.3 V to V _{DD} +0.3 V
Output voltage range	−0.3 V to V _{DD} +0.3 V
Operating free-air temperature range	−40°C to 80°C
Storage temperature range	−55°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

NOTE 1: All voltages are with respect to V_{SS} terminal.

recommended operating conditions

	MIN	TYP	MAX	UNIT
Supply voltage, V _{DD}	4.5	5	5.5	V
High-level input voltage, V _{IH}	2			V
Low-level input voltage, V _{IL}			0.8	V
Clock frequency, f _{clock}	100		900	kHz
Operating free-air temperature, T _A	−40		80	°C

electrical characteristics over recommended ranges of supply voltage and operating free-air temperature

PARAMETER		TEST CONDITIONS	MIN	MAX	UNIT
V _{OH}	High-level output voltage	I _{OH} = -400 μA	2.4	V _{DD}	V
		I _{OH} = -100 μA	V _{DD} -0.5	V _{DD}	
V _{OL}	Low-level output voltage	V _{DD} = 4.5 V to 5.5 V, I _{OL} = 1.6 mA		0.4	V
I _{CC}	Supply current	Standby Operating	BUSYWIRE open, See Note 2	0.2	mA
				1	
C _i	Input capacitance			10	pF
C _o	Output capacitance			10	pF

NOTE 2: These limits apply with all inputs between 0 and 0.5 V or V_{DD} - 0.5 V and V_{DD}. For TTL levels, standby supply current will increase significantly in the input buffers.

timing requirements

		MIN	MAX	UNIT
t _w	Pulse duration, strobe low	100		ns
t _{su1}	Setup time, C7-C0 high or low before strobe↓	60		ns
t _{su2}	Setup time, A2-A0 high or low before strobe↓	20		ns
t _{su3}	Setup time, M1 high or low before strobe	20		ns
t _{su4}	Setup time, R/W high before strobe↓	50		ns
t _{su5}	Setup time, R/W low before strobe ↓	20		ns
t _{h1}	Hold time, data valid after strobe	20		ns
t _{h2}	Hold time, R/W high after strobe↑	20		ns
t _{h3}	Hold time, R/W low after strobe↑	20		ns
t _t	Transition time (see Note 3)	30		ns

NOTE 3: Transition time is defined from the 10% point to the 67% point for the rise time and from the 90% point to the 33% point for the fall time.

PRODUCT SUMMARY

This data is excerpted from the *TSP6100 Custom Masked ROM Data Manual* intended for publication in early 1987

- 128K Bits of Serially Accessed Speech Data
- One-of-16 Chip Select Decode Plus Optional External Chip Select
- Auto Incrementing Address Counter (Presettable by TSP5220C or TSP5110A)
- Built-In Indirect Addressing Logic

description

The TSP6100 is a 128K-bit serial-interface masked ROM that provides economical speech data storage for TSP5220C- or TSP5110A-based speech systems when production volume warrants masking. The TSP6100 is designed for direct connection to the TSP5220C or TSP5110A ROM ports and takes advantage of several special ROM setup instructions provided in these devices. No connection of the TSP6100 to the rest of the speech control system is needed.

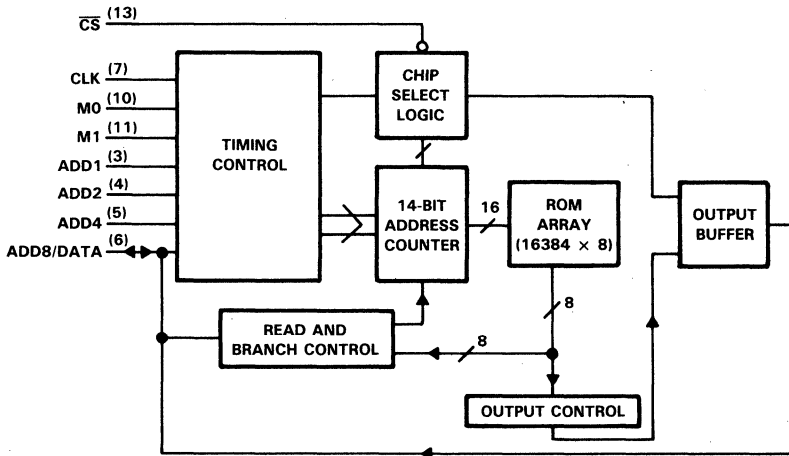

The TSP6100 is characterized for operation from 0°C to 70°C.

D plastic "small outline" packages

Each of these "small outline" packages consists of a circuit mounted on a lead frame and encapsulated within a plastic compound. The compound will withstand soldering temperature with no deformation, and circuit performance characteristics will remain stable when operated in high-humidity conditions. Leads require no additional cleaning or processing when used in soldered assembly.

- NOTES: A. Leads are within 0,25 (0.010) radius of true position at maximum material dimension.
 B. Body dimensions do not include mold flash or protrusion.
 C. Mold flash or protrusion shall not exceed 0,15 (0.006).
 D. Lead tips to be planar within $\pm 0,051$ (0.002) exclusive of solder.

 C. Mold flash or protrusion shall not exceed 0,15 (0.006).
 D. Lead tips to be planar within ±0,051 (0.002) exclusive of solder.

FD and FK leadless ceramic chip carrier packages

Each of these hermetically sealed chip carrier packages has a three-layer ceramic base with a metal lid and braze seal. The packages are intended for surface mounting on solder lands on 1,27 (0.050-inch) centers. Terminals require no additional cleaning or processing when used in soldered assembly.

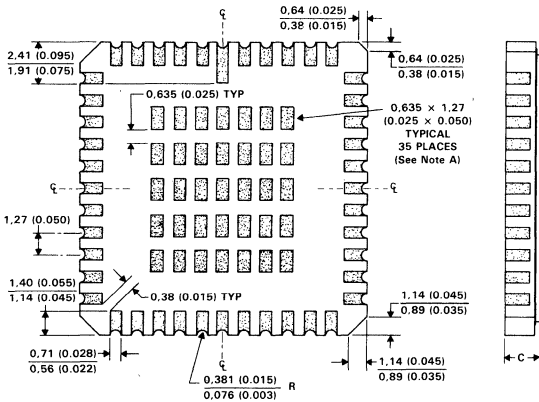

FK package terminal assignments conform to JEDEC standards 1, 2, and 11.

All dimensions and notes for the specified JEDEC outline apply.

ALL LINEAR DIMENSIONS ARE IN MILLIMETERS AND PARENTHETICALLY IN INCHES

- NOTES: A. Centerline of center lead on each side is within 0,10 (0.004) of package centerline as determined by dimension B.
 B. Location of each lead within 0,127 (0.005) of true position with respect to center lead on each side.
 C. The lead contact points are planar within 0,10 (0.004).

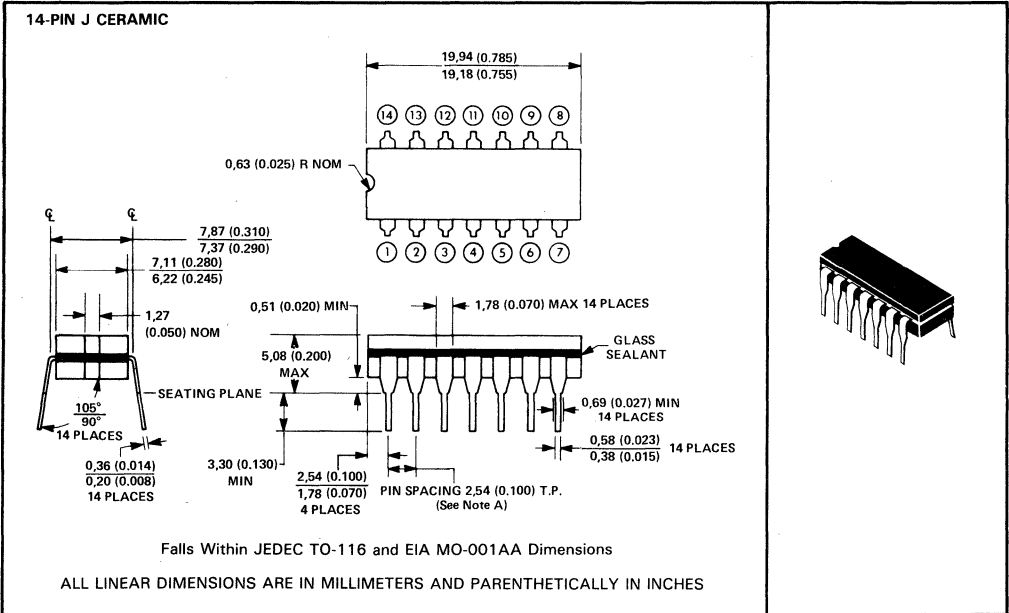

MECHANICAL DATA

†There are two versions of the 48-lead FT package that differ in the position of the index mark in the top view. In one version, the mark is near lead 3, in the other version, it is near lead 46. Consult the individual data sheet to see which applies for a particular device type.

J ceramic dual-in-line package

This hermetically sealed dual-in-line package consists of a ceramic base, ceramic cap, and a lead frame. Hermetic sealing is accomplished with glass. The package is intended for insertion into mounting-hole rows on 7,62 (0.300) centers. Once the leads are compressed and inserted, sufficient tension is provided to secure the package in the board during soldering. Tin-plated ("bright-dipped") leads require no additional cleaning or processing when used in soldered assembly.

NOTE A: Each pin centerline is located within 0,25 (0.010) of its true longitudinal position.

Leads require no additional cleaning or processing when used in soldered assembly.

- NOTES:
- Each pin centerline is located within 0,25 (0.010) of its true longitudinal position.
 - This dimension does not apply for solder-dipped leads.
 - When solder-dipped leads are specified, dipped area of the lead extends from the lead tip to at least 0,51 (0.020) above seating plane.

Mechanical Data

B

N plastic dual-in-line package

This dual-in-line package consists of a circuit mounted on a lead frame and encapsulated within an electrically nonconductive plastic compound. The compound will withstand soldering temperature with no deformation, and circuit performance characteristics will remain stable when operated in high-humidity conditions. The package is intended for insertion in mounting-hole rows on 7,62 (0.300) centers. Once the leads are compressed and inserted, sufficient tension is provided to secure the package in the board during soldering. Leads require no additional cleaning or processing when used in soldered assembly.

- NOTES: A. Each pin centerline is located within 0,25 (0.010) of its true longitudinal position.
 B. This dimension does not apply for solder-dipped leads.
 C. When solder-dipped leads are specified, dipped area of the lead extends from the lead tip to at least 0,51 (0.020) above seating plane.

MECHANICAL DATA

NE plastic dual-in-line packages

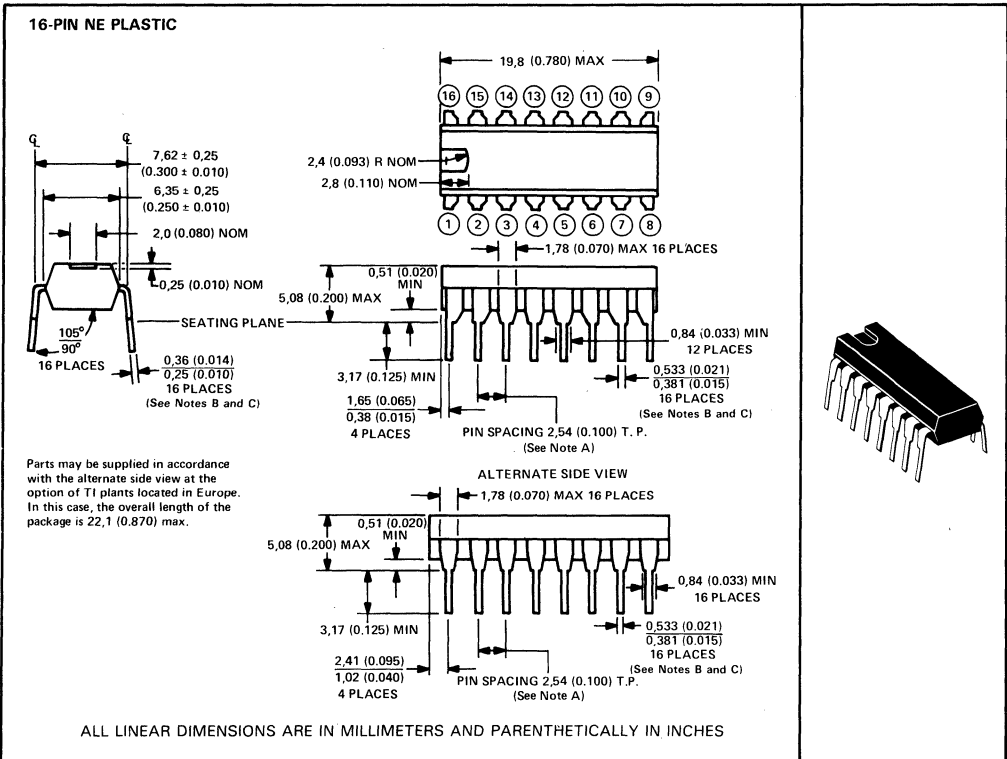

This dual-in-line package consists of a circuit mounted on a 14-pin lead frame and encapsulated within an electrically nonconductive plastic compound. The compound will withstand soldering temperature with no deformation, and circuit performance characteristics will remain stable when operated in high-humidity conditions. For better heat dissipation there are internal tabs connecting the three central leads on each side of the 14-pin package. The package is intended for insertion in mounting-hole rows on 7,62 (0.300) centers. Once the leads are compressed and inserted, sufficient tension is provided to secure the package in the board during soldering. Leads require no additional cleaning or processing when used in soldered assembly.

- NOTES: A. Each pin centerline is located within 0,25 (0.010) of its true longitudinal position. This dimension does not apply for solder-dipped leads.
 B. When solder-dipped leads are specified, dipped area of the lead extends from the lead tip to at least 0,51 (0.020) above seating plane.
 C. When solder-dipped leads are specified, dipped area of the lead extends from the lead tip to at least 0,51 (0.020) above seating plane.

NE plastic dual-in-line packages

This dual-in-line package consists of a circuit mounted on a 16-pin lead frame and encapsulated within an electrically nonconductive plastic compound. The compound will withstand soldering temperature with no deformation, and circuit performance characteristics will remain stable when operated in high-humidity conditions. For better heat dissipation there are internal tabs connecting the two central leads on each side of the 16-pin package. The package is intended for insertion in mounting-hole rows on 7,62 (0.300) centers. Once the leads are compressed and inserted, sufficient tension is provided to secure the package in the board during soldering. Leads require no additional cleaning or processing when used in soldered assembly.

Parts may be supplied in accordance with the alternate side view at the option of T1 plants located in Europe. In this case, the overall length of the package is 22,1 (0.870) max.

- NOTES: A. Each pin centerline is located within 0,25 (0.010) of its true longitudinal position.
 B. This dimension does not apply for solder-dipped leads.
 C. When solder-dipped leads are specified, dipped area of the lead extends from the lead tip to at least 0,51 (0.020) above seating plane.

Mechanical Data

MECHANICAL DATA

NF plastic dual-in-line packages

This dual-in-line package consists of a circuit mounted on a 28-pin lead frame and encapsulated within a plastic compound. The compound will withstand soldering temperature with no deformation, and circuit performance characteristics will remain stable when operated in high-humidity conditions. The package is intended for insertion in mounting-hole rows on 10,16 (0.400) centers. Pin spacing within the rows is 1,78 (0.070). Once the leads are compressed and inserted, sufficient tension is provided to secure the package in the board during soldering. Solder-plated leads require no additional cleaning or processing when used in soldered assembly.

- NOTES: A. Each pin centerline is located within 0,25 (0.010) of its true longitudinal position.
 B. This dimension does not apply for solder-dipped leads.
 C. When solder-dipped leads are specified, dipped area of the lead extends from the lead tip to at least 0,51 (0.020) above seating plane.

P dual-in-line plastic package

This package consists of a circuit mounted on an 8-pin lead frame and encapsulated within a plastic compound. The compound will withstand soldering temperature with no deformation, and circuit performance characteristics will remain stable when operated in high-humidity conditions. The package is intended for insertion in mounting-hole rows on 7,62 (0.300) centers (See Note A). Once the leads are compressed and inserted, sufficient tension is provided to secure the package in the board during soldering. Solder-plated leads require no additional cleaning or processing when used in soldered assembly.

- NOTES: A. Each pin centerline is located within 0,25 (0.010) of its true longitudinal position.
 B. This dimension does not apply for solder-dipped leads.
 C. When solder-dipped leads are specified, dipped area of the lead extends from the lead tip to at least 0,51 (0.020) above seating plane.

MECHANICAL DATA

U ceramic flat package

This flat package consists of a ceramic base, ceramic cap, and lead frame. Circuit bars are alloy mounted. Hermetic sealing is accomplished with glass. Leads require no additional cleaning or processing when used in soldered assembly.

Mechanical Data

B

NOTES: A. Leads are within 0,13 (0.005) radius of true position (T.P.) at maximum material conditions.
 B. This dimension determines a zone within which all body and lead irregularities lie.

W ceramic flat packages

Each of these hermetically sealed flat packages consists of an electrically nonconductive ceramic base and cap and a lead frame. Hermetic sealing is accomplished with glass. Leads require no additional cleaning or processing when used in soldered assembly.

- NOTES: A. Leads are within 0,13 (0.005) radius of true position (T.P.) at maximum material condition.
 B. This dimension determines a zone within which all body and lead irregularities lie.
 C. Index point is provided on cap for terminal identification only.

INTRODUCTION

Texas Instruments has developed solutions for today's high density packaging needs. The TI facility at Attleboro, Massachusetts (one of the world's largest suppliers of multimetal systems) provides leading-edge technology which, combined with reliable, high-volume, off-the-shelf interconnection products, allows TI to quickly meet volume commercial applications.

During the last decade, TI has produced one of the largest IC socket families. TI's sockets include every type and size socket in common use today and are available in a wide choice of contact materials and designs.

Our sockets are designed for:

- ergonomical efficiencies in assembly
- compatibility with automatic assembly equipment
- maximum performance and board density

This section of the data book provides information on the following types of IC socket products.

PRODUCTION SOCKETS	TYPE
Plastic Leaded Chip Carrier	PLCC
Single-in-Line Packages	SIP
Pin-Grid Arrays	PGA
Dual In-Line	DIP
Dual In-Line 0.070-in spacing	Shrink Pack
Quad In-Line	QUIP
BURN-IN/TEST SOCKETS	TYPE
Plastic Leaded Chip Carrier	PLCC
Pin Grid Array	PGA
Dual In-Line	DIP
Dual In-Line 0.070-in spacing	Shrink Pack
Small Outline	Flatpack
Quad	Flatpack

Specially formulated alloys give the TI contact springs:

- Low Contact Resistance
- High Contact Strength (to stand up to repetitive insertions and withdrawals)
- High normal forces, assure gas tight reliability

A full line of reliable, readily available, low-cost interconnection systems means premium performance at an economical price.

Additional information, on these and other TI products, including pricing and delivery quotations may be obtained from your nearest TI Distributor, TI Sales Representative or:

IC SOCKETS

PLASTIC LEADED CHIP CARRIER

PERFORMANCE SPECIFICATIONS

Mechanical

Recommended PCB thickness range: 0.062 in to 0.092 in
 Recommended PCB hole size range: 0.032 in to 0.042 in
 Vibration: 15 G
 Shock: 100 G
 Solderability: Per MIL-STD 202, Method 208
 Insertion force: 0.59 lbs per position
 Withdrawal force: 0.25 lbs per position
 Normal force: 200 g min, 450 g typ
 Wipe: 0.075 in min
 Durability: 5 cycles min
 Contact retention: 1.5 lbs min

Electrical

Current carrying capacity: 1 A
 Insulation resistance: 5000 MΩ min
 Dielectric withstanding voltage: 1000 V ac rms min
 Capacitance: 1.0 pF max

Environmental

Operating temperature:
 Operating: -40°C to 85°C
 Storage: -40°C to 95°C
 Temperature cycling with humidity: will conform to final EIA specifications
 Shelf life: 1 year min

MATERIALS

Body - Ryton R-4 (40% glass) U/L 94-VO rating
 Contacts - CDA 510 spring temper
 Contact finish - 90/10 tin (200 μin - 400 μin) over 40 μin copper

TEXAS INSTRUMENTS

34 Forest Street • Attleboro, Massachusetts 02703

PRODUCT FEATURES

Can be loaded by top actuated insertion or press-in insertion, either manually or automatically
High reliability due to high pressure contact point
Open body and high stand-off design provide high efficiency in heat dissipation
High durability up to 10,000 cycles
Compact design

PERFORMANCE SPECIFICATIONS

Mechanical

Durability: 10,000 cycles
Operating Temperature: 180°C max

Electrical

Contact rating: 1.0 A per contact
Contact resistance: 30 mΩ max
Insulation resistance: 1000 MΩ min
Dielectric withstanding voltage: 500 V ac rms min

MATERIALS

Body — ultem glass filled (U/L 94 VO)
Contact — copper alloy
Plating — overall gold plate

IC SOCKETS HIGH DENSITY PIN GRID ARRAY

PERFORMANCE SPECIFICATIONS

Mechanical

Accommodates IC leads 0.015 in to 0.021 in diameter
Recommended PCB thickness range: 0.062 in to 0.092 in
Recommended PCB hole size range: 0.032 in to 0.042 in
Recommended hole grid pattern: 0.100 in \pm 0.002 in each direction

Vibration: 15 G, 10-2000 Hz per MIL-STD 1344A, Method 2005.1 Test Condition III

Shock: 100 G, sawtooth waveform, 2 shocks each direction per MIL-STD 202, Method 213, Test Condition I

Durability: 5 cycles, 10 m Ω max contact resistance change per MIL-STD 1344, Method 2016

Solderability: per MIL-STD 202, Method 208

Insertion force: 3.6 oz (102 g) per pin typ using 0.018 in diameter test pin

Withdrawal force: 0.5 oz (14 g) per pin min using 0.018 in diameter test pin

Electrical

Contact rating: 1.0 A per contact

Contact resistance: 20 m Ω max initial

Insulation resistance: 1000 M Ω at 500 V dc per MIL-STD 1344, Method 3003.1

Dielectric withstanding voltage: 1000 V ac rms per MIL-STD 1344, Method 3001.1

Capacitance: 1.0 pF max per MIL-STD 202, Method 305

Environmental

Operating temperature: -65°C to 125°C, gold; -40°C to 100°C, tin

Corrosive atmosphere: 10 m Ω max contact resistance change when exposed to 22% ammonium sulfide for 4 hours

Gas tight: 10 m Ω max contact resistance change when exposed to nitric acid vapor for 1 hour

Temperature soak: 10 m Ω max contact resistance change when exposed to 105°C temperature for 48 hours

Shell life: 12 months min

MATERIALS

Body - PBT polyester U/L94-VO rating

On request, G10/FR4 or Mylar film

Outer sleeve - Machined Brass (QQ-B-626)

Inner contact - Beryllium copper (QQ-C-530) heat treated

Plating: (specified by part number)

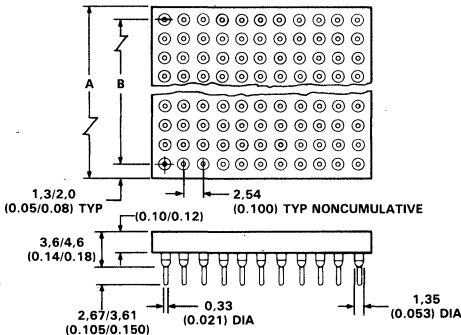

Inner contact - 30 μ m gold over 50 μ m nickel or 100 μ m tin/lead over 50 μ m nickel

Outer sleeve - 10 μ m gold over 50 μ m nickel or 50 μ m tin/lead over 50 μ m nickel

PERFORMANCE SPECIFICATIONS

Mechanical

Accommodates IC leads 0.011 in by 0.018 in NOM
 Recommended PCB thickness range: 0.062 in to 0.092 in
 Recommended PCB hold size range: 0.032 in to 0.042 in
 Durability: 10K cycles — CM Series, 5K cycles — CP/CQ
 Solderability: per MIL-STD 202, Method 208

Electrical

Contact rating: 1.0 A per contact
 Contact resistance: 20 mΩ max initial
 Insulation resistance: 1000 MΩ at 500 V dc
 Dielectric withstanding voltage: 1000 V ac rms
 Capacitance: 1.0 pF max per MIL-STD 202, Method 305

Environmental

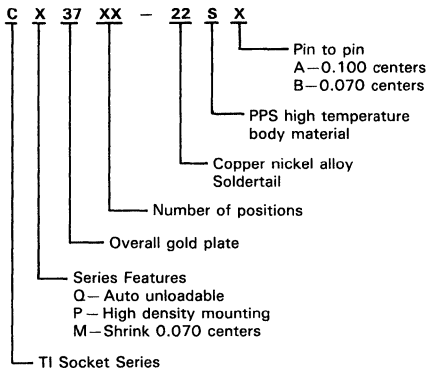

Operating temperature: -65°C to 170°C — CP/CM Series,
 -65°C to 150°C — CQ Series
 Humidity: 10 mΩ max contact resistance
 Temperature Soak: 10 mΩ max contact resistance change

MATERIALS

Body — PPS (polyphenylen sulfide) glass filled U/L 94 VO
 Contacts — Higher performance copper nickel alloy
 Plating: † 4 μin of gold min over 100 μin of nickel min

† For additional plating options consult the factory

1 Introduction

The International Electrotechnical Commission (IEC) has been developing a very powerful symbolic language that can show the relationship of each input of a digital logic circuit to each output without showing explicitly the internal logic. At the heart of the system is dependency notation, which will be explained in Section 4.

The system was introduced in the USA in a rudimentary form in IEEE/ANSI Standard Y32.14-1973. Lacking at that time a complete development of dependency notation, it offered little more than a substitution of rectangular shapes for the familiar distinctive shapes for representing the basic functions of AND, OR, negation, etc. This is no longer the case.

Internationally, Working Group 2 of IEC Technical Committee TC-3 has prepared a new document (Publication 617-12) that consolidates the original work started in the mid 1960's and published in 1972 (Publication 117-15) and the amendments and supplements that have followed. Similarly for the USA, IEEE Committee SCC 11.9 has revised the publication IEEE Std 91/ANSI Y32.14. Now numbered simply ANSI/IEEE Std 91-1984, the IEEE standard contains all of the IEC work that has been approved, and also a small amount of material still under international consideration. Texas Instruments is participating in the work of both organizations and this document introduces new logic symbols in accordance with the new standards. When changes are made as the standards develop, future editions will take those changes into account.

The following explanation of the new symbolic language is necessarily brief and greatly condensed from what the standards publications now contain. This is not intended to be sufficient for those people who will be developing symbols for new devices. It is primarily intended to make possible the understanding of the symbols used in this data book and is somewhat briefer than the explanation that appears in several of TI's data books on digital logic. However, it includes a new section (6.0) that explains several symbols for actual devices in detail. This has proven to be a powerful learning aid.

2 Symbol Composition

A symbol comprises an outline or a combination of outlines together with one or more qualifying symbols. The shape of the symbols is not significant. As shown in Figure 1, general qualifying symbols are used to tell exactly what logical operation is performed by the elements. Table 1 shows general qualifying symbols defined in the new standards. Input lines are placed on the left and output lines are placed on the right. When an exception is made to that convention, the direction of signal flow is indicated by an arrow as shown in Figure 9.

*Possible positions for qualifying symbols relating to inputs and outputs

Figure 1. Symbol Composition

3 Qualifying Symbols

3.1 General Qualifying Symbols

Table 1 shows general qualifying symbols defined by ANSI/IEEE Standard 91. These characters are placed near the top center or the geometric center of a symbol or symbol element to define the basic function of the device represented by the symbol or of the element.

X/Y is the general qualifying symbol for identifying coders, code converters, and level converters. X and Y may be used in their own right to stand for some code or either or both may be replaced by some other indication of the code or level such as BCD or TTL. As might be expected, interface circuits make frequent use of this set of qualifying symbols.

Table 1. General Qualifying Symbols

SYMBOL	DESCRIPTION
&	AND gate or function
≥ 1	OR gate or function. The symbol was chosen to indicate that at least one active input is needed to activate the output.
= 1	Exclusive OR. One and only one input must be active to activate the output.
1	A simple 1-input gate or element
\triangleright or \triangleleft	A buffer or element with more than usual output capability (symbol is oriented in the direction of signal flow).
\square	Schmitt trigger; element with hysteresis
X/Y	Coder, code converter, level converter

The following are examples of subsets of this general class of qualifying symbol used in this book.

BCD/7-SEG	BCD to 7-segment display driver
TTL/MOS	TTL to MOS level converter
CMOS/PLASMA DISP	Plasma-display driver with CMOS-compatible inputs
MOS/LED	Light-emitting-diode driver with MOS-compatible inputs
CMOS/VAC FLUOR DISP	Vacuum-fluorescent display driver with CMOS-compatible inputs
CMOS/EL DISP	Electroluminescent display driver with CMOS-compatible inputs
TTL/GAS DISCH DISPLAY	Gas-discharge display driver with TTL-compatible inputs
SRGm	Shift register. m = number of bits.

3.2 Qualifying Symbols for Inputs and Outputs

Qualifying symbols for inputs and outputs are shown in Table 2 and many will be familiar to most users, a likely exception being the logic polarity symbol for directly indicating active-low inputs and outputs. The older logic negation indicator means that the external 0 state produces the internal 1 state. The internal 1 state means the active state. Logic negation may be used in pure logic diagrams; in order to tie the external 1 and 0 logic states to the levels H (high) and L (low), a statement of whether positive logic (1 = H, 0 = L) or negative logic (1 = L, 0 = H) is being used is required or must be assumed. Logic polarity indicators eliminate the need for calling out the logic convention and are used in this data book in the symbology for actual devices. The presence of the triangle polarity indicator indicates that the L logic level will produce the internal 1 state (the active state) or that, in the case of an output, the internal 1 state will produce the external L level. Note how the active direction of transition for a dynamic input is indicated in positive logic, negative logic, and with polarity indication.

When nonstandardized information is shown inside an outline, it is usually enclosed in square brackets [like these]. The square brackets are omitted when associated with a nonlogic input, which is indicated by an X superimposed on the connection line outside the symbol.

Table 2. Qualifying Symbols for Inputs and Outputs

	Logic negation at input. External 0 produces internal 1.
	Logic negation at output. Internal 1 produces external 0.
	Active-low input. Equivalent to $\overline{0}$ in positive logic
	Active-low output. Equivalent to $\overline{1}$ in positive logic
	Active-low input in the case of right-to-left signal flow
	Active-low output in the case of right-to-left signal flow
	Signal flow from right to left. If not otherwise indicated, signal flow is from left to right.
	Bidirectional signal flow

	Nonlogic connection. A label inside the symbol will usually define the nature of this pin.
	Input for analog signals (on a digital symbol) (see Figure 11)
	Input for digital signals (on an analog symbol) (see Figure 11)

3.3 Symbols Inside the Outline

Table 3 shows some symbols used inside the outline. Note particularly that open-collector (open-drain), open-emitter (open-source), and three-state outputs have distinctive symbols. Also note that an EN input affects all of the outputs of the element and has no effect on inputs. An EN input affects all the external outputs of the element in which it is placed, plus the external outputs of any elements shown to be influenced by that element. It has no effect on inputs. When an enable input affects only certain outputs, affects outputs located outside the indicated influence of the element in which the enable input is placed, and/or affects one or more inputs, a form of dependency notation will indicate this (see 4.9). The effects of the EN input on the various types of outputs are shown.

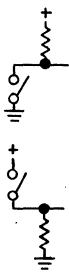

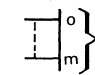

It is particularly important to note that a D input is always the data input of a storage element. At its internal 1 state, the D input sets the storage element to its 1 state, and at its internal 0 state it resets the storage element to its 0 state.

The binary grouping symbol will be explained more fully in Section 6.11. Binary-weighted inputs are arranged in order and the binary weights of the least significant and the most significant lines are indicated by numbers. In this document weights of input and output lines will be represented by powers of two usually only when the binary grouping symbol is used, otherwise decimal numbers will be used. The grouped inputs generate an internal number on which a mathematical function can be performed or that can be an identifying number for dependency notation. This number is the sum of the weights (1, 2, 4, . . . 2ⁿ) of those input standing at their 1 states. A frequent use is in addresses for memories.

Reversed in direction, the binary grouping symbol can be used with outputs. The concept is analogous to that for the inputs and the weighted outputs will indicate the internal number assumed to be developed within the circuit.

Table 3. Symbols Inside the Outline

	Bithreshold input (input with hysteresis)	
	N-P-N open-collector or similar output that can supply a relatively low-impedance L level when not turned off. Requires external pull-up. Capable of positive-logic wired-AND connection.	
	Passive-pull-up output is similar to N-P-N open-collector output but is supplemented with a built-in passive pull-up.	
	N-P-N open-emitter or similar output that can supply a relatively low-impedance H level when not turned off. Requires external pull-down. Capable of positive-logic wired-OR connection.	
	Passive-pull-down output is similar to N-P-N open-emitter output but is supplemented with a built-in passive pull-down.	
	3-state output	
	Output with more than usual output capability (symbol is oriented in the direction of signal flow).	
	Enable input When at its internal 1-state, all outputs are enabled. When at its internal 0-state, open-collector, open-emitter outputs, and three-state outputs at external high-impedance state, and all other outputs (i.e., totem-poles) are at the internal 0-state.	
J, K, R, S, T	Usual meanings associated with flip-flops (e.g., R = reset, T = toggle)	
	Data input to a storage element equivalent to:	
	Shift right (left) inputs, m = 1, 2, 3, etc. If m = 1, it is usually not shown.	
	Binary grouping. m is highest power of 2. Produces a number equal to the sum of the weights of the active inputs	
	Input line grouping . . . indicates two or more terminals used to implement a single logic input. e.g., differential inputs.	

3.4 Combinations of Outlines and Internal Connections

When a circuit has one or more inputs that are common to more than one element of the circuit, the common-control block may be used. This is the only distinctively shaped outline used in the IEC system. Figure 2 shows that unless otherwise qualified by dependency notation, an input to the common-control block is an input to each of the elements below the common-control block.

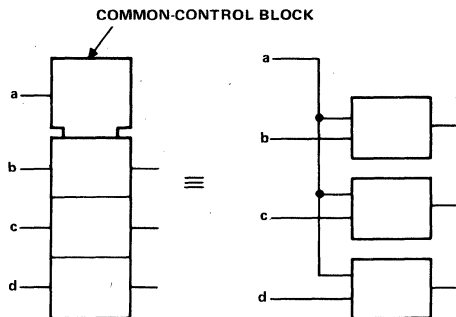

Figure 2. Common-Control Block

The outlines of elements may be embedded within one another or abutted to form complex elements, in which case the following rules apply. There is no logic connection between elements when the line common to their outlines is in the direction of signal flow. There is at least one logic connection when the line common to two outlines is perpendicular to the direction of signal flow. If no indications are shown on either side of the common line, it is assumed that there is only one logic connection. If more than one internal connection exists between adjacent elements, the number of connections will be clarified by the use of one or more of the internal connection symbols from Table 4 and/or appropriate qualifying symbols or dependency notation.

Table 4. Symbols for Internal Connections

	Internal connection. 1 state on left produces 1 state on right.
	Negated internal connection. 1 state on left produces 0 state on right.
	Dynamic internal connection. Transition from 0 to 1 on left produces transitory 1 state on right.
	Dynamic internal connection. Transition from 1 to 0 on left produces transitory 1 state on right.

Table 4 shows symbols that are used to represent internal connection with specific characteristics. The first is a simple noninverting connection, the second is inverting, the third is dynamic. As with this symbol and an external input line, the transition from 0 to 1 on the left produces a momentary 1-state on the right. The fourth symbol is similar except that the active transition on the left is from 1 to 0.

Only logic states, not levels, exist inside symbols. The negation symbol (O) is used internally even when direct polarity indication (∇) is used externally.

In an array of elements, if the same general qualifying symbol and the same qualifying symbols associated with inputs and outputs would appear inside each of the elements of the array, these qualifying symbols are usually shown only in the first element. This is done to reduce clutter and to save time in recognition. Similarly, large identical elements that are subdivided into smaller elements may each be represented by an unsubdivided outline. The SN75163B symbol (see 6.8) illustrates this principle.

4 Dependency Notation

Some readers will find it more to their liking to skip this section and proceed to the explanation of the symbols for a few actual devices in 6.0. Reference will be made there to various parts of this section as it is needed. If this procedure is followed, it is recommended that 5.0 be read after 6.0 and then all of 4.0 be reread.

4.1 General Explanation

Dependency notation is the powerful tool that sets the IEC symbols apart from previous systems and makes compact, meaningful, symbols possible. It provides the means of denoting the relationship between inputs, outputs, or inputs and outputs without actually showing all the elements and interconnections involved. The information provided by dependency notation supplements that provided by the qualifying symbols for an element's function.

In the convention for the dependency notation, use will be made of the terms "affecting" and "affected." In cases where it is not evident which inputs must be considered as being the affecting or the affected ones (e.g., if they stand in an AND relationship), the choice may be made in any convenient way.

So far, eleven types of dependency have been defined but only the eight used in this book are explained. They are listed below in the order in which they are presented and are summarized in Table 5 following 4.10.2.

Section	Dependency Type or Other Subject
4.2	G, AND
4.3	General Rules for Dependency Notation
4.4	V, OR
4.5	N, Negate (Exclusive-OR)
4.6	Z, Interconnection
4.7	X, Transmission
4.8	C, Control
4.9	EN, Enable
4.10	M, Mode

4.2 G (AND) Dependency

A common relationship between two signals is to have them ANDed together. This has traditionally been shown by explicitly drawing an AND gate with the signals connected to the inputs of the gate. The 1972 IEC publication and the 1973 IEEE/ANSI standard showed several ways to show this AND relationship using dependency notation. While ten other forms of dependency have since been defined, the ways to invoke AND dependency are now reduced to one.

In Figure 3 input *b* is ANDed with input *a* and the complement of *b* is ANDed with *c*. The letter G has been chosen to indicate AND relationships and is placed at input *b*, inside the symbol. A number considered appropriate by the symbol designer (1 has been used here) is placed after the letter G and also at each affected input. Note the bar over the 1 at input *c*.

Figure 3. G Dependency Between Inputs

In Figure 4, output *b* affects input *a* with an AND relationship. The lower example shows that it is the internal logic state of *b*, unaffected by the negation sign, that is ANDed. Figure 5 shows input *a* to be ANDed with a dynamic input *b*.

Figure 4. G Dependency Between Outputs and Inputs

Figure 5. G Dependency with a Dynamic Input

The rules for G dependency can be summarized thus:

When a Gm input or output (m is a number) stands at its internal 1 state, all inputs and outputs affected by Gm stand at their normally defined internal logic states. When the Gm input or output stands at its 0 state, all inputs and outputs affected by Gm stand at their internal 0 states.

4.3 Conventions for the Application of Dependency Notation in General

The rules for applying dependency relationships in general follow the same pattern as was illustrated for G dependency.

Application of dependency notation is accomplished by:

1. Labeling the input (or output) *affecting* other inputs or outputs with the letter symbol indicating the relationship involved (e.g., G for AND) followed by an identifying number, appropriately chosen, and
2. Labeling each input or output *affected* by that affecting input (or output) with that same number.

If it is the complement of the internal logic state of the affecting input or output that does the affecting, then a bar is placed over the identifying numbers at the affected inputs or outputs (Figure 3).

If two affecting inputs or outputs have the same letter and same identifying number, they stand in an OR relationship to each other (Figure 6).

Figure 6. ORed Affecting Inputs

If the affected input or output requires a label to denote its function (e.g., "D"), this label will be *prefixed* by the identifying number of the affecting input (Figure 12).

If an input or output is affected by more than one affecting input, the identifying numbers of each of the affecting inputs will appear in the label of the affected one, separated by commas. The normal reading order of these numbers is the same as the sequence of the affecting relationships (Figure 12).

4.4 V (OR) Dependency

The symbol denoting OR dependency is the letter V (Figure 7).

When a Vm input or output stands at its internal 1 state, all inputs and outputs affected by Vm stand at their internal 1 states. When the Vm input or output stands at its internal 0 state, all inputs and outputs affected by Vm stand at their normally defined internal logic states.

Figure 7. V (OR) Dependency

4.5 N (Negate) (Exclusive-OR) Dependency

The symbol denoting negate dependency is the letter N (Figure 8). Each input or output affected by an Nm input or output stands in an Exclusive-OR relationship with the Nm input or output.

When an Nm input or output stands at its internal 1 state, the internal logic state of each input and each output affected by Nm is the complement of what it would otherwise be. When an Nm input or output stands at its internal 0 state, all inputs and outputs affected by Nm stand at their normally defined internal logic states.

Figure 8. N (Negate) (Exclusive-OR) Dependency

4.6 Z (Interconnection) Dependency

The symbol denoting interconnection dependency is the letter Z.

Interconnection dependency is used to indicate the existence of internal logic connections between inputs, outputs, internal inputs, and/or internal outputs.

The internal logic state of an input or output affected by a Zm input or output will be the same as the internal logic state of the Zm input or output, unless modified by additional dependency notation (Figure 9).

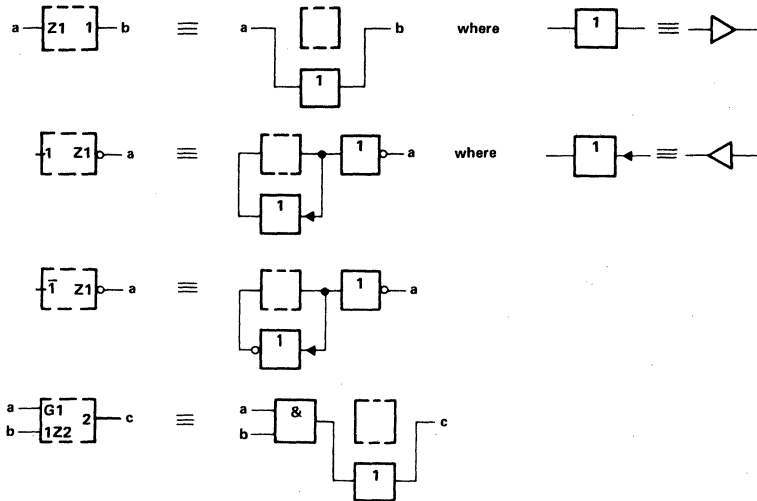

Figure 9. Z (Interconnection) Dependency

4.7 X (Transmission) Dependency

The symbol denoting transmission dependency is the letter X.

Transmission dependency is used to indicate controlled bidirectional connections between affected input/output ports (Figure 10).

When an X_m input or output stands at its internal 1 state, all input-output ports affected by this X_m input or output are bidirectionally connected together and stand at the same internal logic state or analog signal level. When an X_m input or output stands at its internal 0 state, the connection associated with this set of dependency notation does not exist.

Figure 10. X (Transmission) Dependency

Although the transmission paths represented by X dependency are inherently bidirectional, use is not always made of this property. This is analogous to a piece of wire, which may be constrained to carry current in only one direction. If this is the case in a particular application, then the directional arrows shown in Figures 10 and 11 would be omitted.

Figure 11. Analog Data Selector (Multiplexer/Demultiplexer)

4.8 C (Control) Dependency

The symbol denoting control dependency is the letter C.

Control inputs are usually used to enable or disable the data (D, J, K, R, or S) inputs of storage elements. They may take on their internal 1 states (be active) either statically or dynamically. In the latter case the dynamic input symbol is used as shown in the second example of Figure 12.

When a C_m input or output stands at its internal 1 state, the inputs affected by C_m have their normally defined effect on the function of the element, i.e., these inputs are enabled. When a C_m input or output stands at its internal 0 state, the inputs affected by C_m are disabled and have no effect on the function of the element.

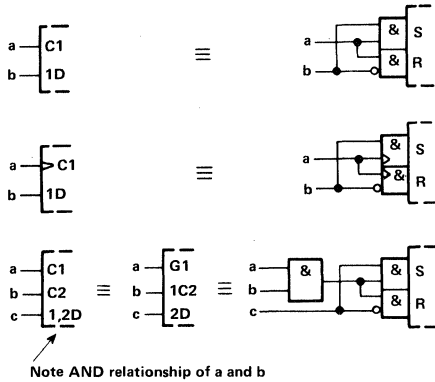

Figure 12. C (Control) Dependency

4.9 EN (Enable) Dependency

The symbol denoting enable dependency is the combination of letters EN.

An EN_m input has the same effect on outputs as an EN input, see 3.3, but it affects only those outputs labeled with the identifying number m . It also affects those inputs labeled with the identifying number m . By contrast, an EN input affects all outputs and no inputs. The effect of an EN_m input on an affected input is identical to that of a C_m input (Figure 13).

Figure 13. EN (Enable) Dependency

When an EN_m input stands at its internal 1 state, the inputs affected by EN_m have their normally defined effect on the function of the element and the outputs affected by this input stand at their normally defined internal logic states, i.e., these inputs and outputs are enabled.

When an EN_m input stands at its internal 0 state, the inputs affected by EN_m are disabled and have no effect on the function of the element, and the outputs affected by EN_m are also disabled. Open-collector outputs are turned off, three-state outputs stand at their high-impedance state, and all other outputs (e.g., totem-pole outputs) stand at their internal 0 states.

4.10 M (MODE) Dependency

The symbol denoting mode dependency is the letter M.

Mode dependency is used to indicate that the effects of particular inputs and outputs of an element depend on the mode in which the element is operating.

If an input or output has the same effect in different modes of operation, the identifying numbers of the relevant affecting M_m inputs will appear in the label of that affected input or output between parentheses and separated by solidi, e.g., $(1/2)CT=0 \equiv 1CT=0/2CT=0$ where 1 and 2 refer to M1 and M2.

4.10.1 M Dependency Affecting Inputs

M dependency affects inputs the same as C dependency. When an *Mm* input or *Mm* output stands at its internal 1 state, the inputs affected by this *Mm* input or *Mm* output have their normally defined effect on the function of the element, i.e., the inputs are enabled.

When an *Mm* input or *Mm* output stands at its internal 0 state, the inputs affected by this *Mm* input or *Mm* output have no effect on the function of the element. When an affected input has several sets of labels separated by solidi (e.g., C4/2→/3+), any set in which the identifying number of the *Mm* input or *Mm* output appears has no effect and is to be ignored. This represents disabling of some of the functions of a multifunction input.

The circuit in Figure 14 has two inputs, *b* and *c*, that control which one of four modes (0, 1, 2, or 3) will exist at any time. Inputs *d*, *e*, and *f* are D inputs subject to dynamic control (clocking) by the *a* input. The numbers 1 and 2 are in the series chosen to indicate the modes so inputs *e* and *f* are only enabled in mode 1 (for parallel loading) and input *d* is only enabled in mode 2 (for serial loading). Note that input *a* has three functions. It is the clock for entering data. In mode 3, it causes the contents of the register to be incremented by one count.

Note that all operations are synchronous.

In MODE 0 ($b = 0, c = 0$), the outputs remain at their existing states as none of the inputs has an effect.

In MODE 1 ($b = 1, c = 0$), parallel loading takes place thru inputs *e* and *f*.

In MODE 2 ($b = 0, c = 1$), shifting down and serial loading thru input *d* take place.

In MODE 3 ($b = c = 1$), counting up by increment of 1 per clock pulse takes place.

Figure 14. M (Mode) Dependency Affecting Inputs

4.10.2 M Dependency Affecting Outputs

When an *Mm* input or *Mm* output stands at its internal 1 state, the affected outputs stand at their normally defined internal logic states, i.e., the outputs are enabled.

When an *Mm* input or *Mm* output stands at its internal 0 state, at each affected output any set of labels containing the identifying number of that *Mm* input or *Mm* output has no effect and is to be ignored. When an output has several different sets of labels separated by solidi (e.g., 2,4/3,5), only those sets in which the identifying number of this *Mm* input or *Mm* output appears are to be ignored.

Figure 15 shows a symbol for a device whose output can behave like either a 3-state output or an open-collector output depending on the signal applied to input *a*. Mode 1 exists when input *a* stands at its internal 1 state and, in that case, the three-state symbol applies and the open-element symbol has no effect. When $a = 0$, mode 1 does not exist so the three-state symbol has no effect and the open-element symbol applies.

Figure 15. Type of Output Determined by Mode

Table 5. Summary of Dependency Notation

TYPE OF DEPENDENCY	LETTER SYMBOL*	AFFECTING INPUT AT ITS 1-STATE	AFFECTING INPUT AT ITS 0-STATE
Control	C	Permits action	Prevents action
Enable	EN	Permits action	Prevents action of inputs ◇ outputs turned off ▽ outputs at external high impedance Other outputs at internal 0 state
AND	G	Permits action	Imposes 0 state
Mode	M	Permits action (mode selected)	Prevents action (mode not selected)
Negate (Ex-NOR)	N	Complements state	No effect
OR	V	Imposes 1 state	Permits action
Transmission	X	Bidirectional connection exists	Bidirectional connection does not exist
Interconnection	Z	Imposes 1 state	Imposes 0 state

* These letter symbols appear at the AFFECTING input (or output) and are followed by a number. Each input (or output) AFFECTED by that input is labeled with that same number.

5 Bistable Elements

The dynamic input symbol and dependency notation provide the tools to identify different types of bistable elements and make synchronous and asynchronous inputs easily recognizable (Figure 16).

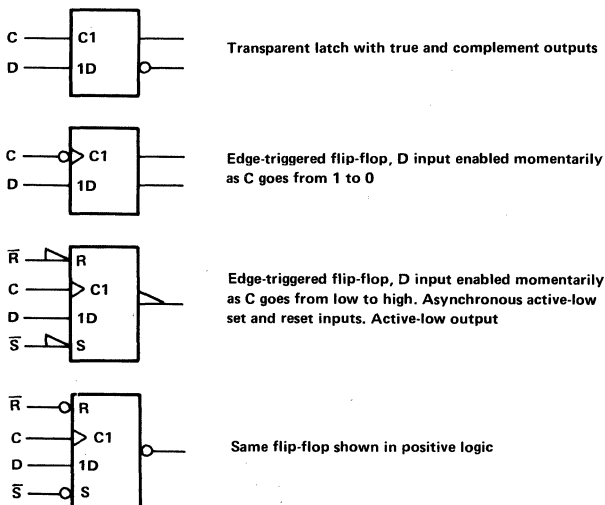

Figure 16. Latches and Flip-Flops

Transparent latches have a level-operated control input. The D input is active as long as the C input is at its internal 1 state. The outputs respond immediately. Edge-triggered elements accept data from D, J, K, R, or S inputs on the active transition of C.

Notice that synchronous inputs can be readily recognized by their dependency labels (a number preceding the functional label, 1D in these examples) compared to the asynchronous inputs (S and R), which are not dependent on the C inputs. Of course if the set and reset inputs were dependent on the C inputs, their labels would be similarly modified (e.g., 1S, 1R).

6 Examples of Actual Device Symbols

The symbols explained in this section include some of the most complex in this book. These were chosen, not to discourage the reader, but to illustrate the amount of information that can be conveyed. It is likely that if one reads these explanations and follows them reasonably well, most of the other symbols will seem simple indeed. The explanations are intended to be independent of each other so they may seem somewhat repetitious. However each illustrates new principles. They are arranged more or less in the order of complexity.

6.1 UDN2841 High-Current Darlington Drivers

There are four identical sections. The emitters of the output transistors of the elements numbered 1 and 3 are connected together and share pins 4, 5, 12, and 13. The triangular qualifying symbol (\triangleright) indicates amplification, the principal function of the device.

An extension of symbology used for analog devices has been used to show the output transistors. The emitter and collector terminals are lined up with the terminals to which they are connected.

6.2 SN75437 Quadruple Peripheral Driver

There are four identical sections. The symbology is complete for the first element; the absence of any symbology for the other elements indicates they are identical. The top two elements share a common output clamp, pin 2. This is shown to be a nonlogic connection by the superimposed X on the line. The function for this type of connection is indicated briefly and not necessarily exactly by a small amount of text within the symbol. The bottom two elements likewise share a common clamp.

Each element is shown to be an inverter with amplification (indicated by \triangleright). Taking TTL as a reference, this means that either the input is sensitive to lower level signals, or the output has greater drive capability than usual. The latter applies in this case. The output is shown by \diamond to be open collector.

All the outputs share a common EN input, pin 14. See Figure 2 for an explanation of the common control block. When EN = 0 (pin 14 is low), the outputs, being open-collector types, are turned off and would be pulled high by an external pullup resistor.

6.3 TL607 Analog Switch with Enable

by affecting input number 3, which is G3. This is coincidentally pin number 3. This means that both the active-high branch of pin 2 (X1) and the active-low branch (X2) are ANDed with pin 3. See 4.2 for an explanation of G (AND) dependency. If pin 3 is low, both X1 and X2 will be at the 0-state and both switches will be off. If pin 3 is high and pin 2 is high, X1 will be at the 1-state, X2 will be at the 0-state, and only the switch between pins 4 and 6 will be on. If pin 3 is high and pin 2 is low, X1 will be at the 0-state, X2 will be at the 1-state, and only the switch between pins 4 and 7 will be on.

6.4 SN75128 8-Channel Line Receiver

The top four outputs are shown to be affected by affecting input number 1, which is EN1, meaning they will be enabled if EN1 = 1 (pin 1 is high). See 4.9 for an explanation of EN dependency. If pin 1 is low, EN1 = 0 and the affected outputs will go to their inactive (high) levels. Similarly, the lower four outputs are controlled by pin 11.

This device is basically two single-pole, single-throw (SPST) switches connected between pins 4 and 6 and pins 4 and 7. This is indicated using X (Transmission) dependency, which is explained in 4.7. When the internal input X2 stands at its 1-state, a bilateral connection exists between those points affected by X2: pins 4 and 7. The 1 at pins 4 and 6 means they are affected by X1; X1 must stand at the 1-state to establish a connection between them.

The numeral 3 in front of X1 and X2 indicates that both of these internal inputs are themselves affected

There are eight identical sections. The symbology is complete for the first element; the absence of any symbology for the next three elements indicates they are identical. Likewise the symbology is complete for the fifth element; the absence of any symbology for the next three elements indicates they are identical to the fifth.

Each element is shown to be an inverter with amplification (indicated by \triangleright). Taking TTL as a reference, this means that either the input is sensitive to lower level signals, or the output has greater drive capability than usual. The former applies in this case. Since neither the symbol for open-collector (\diamond) or 3-state (∇) outputs is shown, the outputs are of the totem-pole type.

6.7 SN75113 Differential Line Drivers with Split 3-State Outputs

There are two similar elements in the array. The first is a 2-input AND element (indicated by &); the second has only a single input. Both elements are shown to have special amplification (indicated by \triangleright). Taking TTL as a reference, this means that either the input is sensitive to lower level signals, or the output has greater drive capability than usual. The latter applies in this case.

Each element has four outputs. Pins 4 and 3 are a pair consisting of one open-emitter output (\diamond) and one open-collector output (\square). Relative to the AND function, both are active high. Pins 1 and 2 are a similar pair but relative to the AND function, both are active low. All outputs of a single, unsubdivided element always have identical internal logic states determined by the function of the element except when otherwise indicated by an associated symbol or label inside the element. Here there is no such contrary indication. All four outputs are shown to be affected by affecting input number 1, which is EN1,

meaning they will all be enabled if $EN1 = 1$. See 4.9 for an explanation of EN dependency. If $EN1 = 0$, all the affected outputs will be turned off. EN1 is the output of an AND gate (indicated by &) whose active-high inputs are pins 7 and 9. Both pins 7 and 9 must be high to enable the outputs of the top element. Assuming they are enabled and that pins 5 and 6 are both high, the internal state of all four outputs will be a 1. Pins 4 and 3 will both be high, pins 1 and 2 will both be low. The part is designed so that pins 3 and 4 may be connected together creating an active-high 3-state output. Likewise pins 1 and 2 may be connected together to create an active-low 3-state output.

All that has been said about the first element regarding its outputs and their enable inputs also applies to the second element. Pins 9 and 10 are the enable inputs in this case.

6.8 SN75163B Octal General-Purpose Interface Bus Transceiver

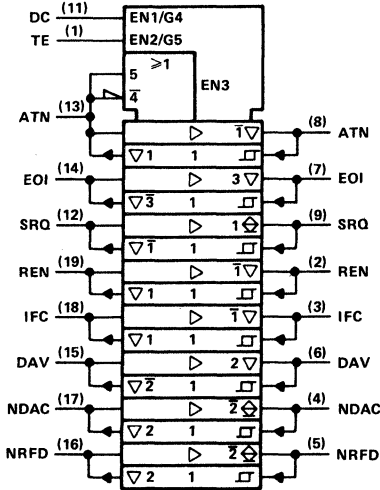

There are eight I/O ports on each side, pins 2 through 9 and 12 through 19. There are eight identical channels. The symbology is complete for the first channel; the absence of any symbology for the other channels indicates they are identical. The eight bidirectional channels each have amplification from left to right, that is, the outputs on the right have increased drive capability (indicated by \triangleright), and the inputs on the right all have hysteresis (indicated by \square).

The outputs on the left are shown to be 3-state outputs by the ∇ . They are also shown to be affected by affecting input number 4, which is EN4, meaning they will be enabled if $EN4 = 1$ (pin 1 is low). See 4.9 for an explanation of EN dependency. If $EN4 = 0$ (pin 1 is high), the affected outputs will go to their high-impedance (off) states.

The labeling at pin 2, which applies to all the outputs on the right, is unusual because the outputs themselves have an unusual feature. The label includes both the symbol for a 3-state output (∇) and for an open-collector output (\square), separated by a slash indicating that these are alternatives.

The symbol for the 3-state output is shown to be affected by affecting input number 1, which is M1, meaning the ∇ label is valid when M1 = 1 (pin 11 is high), but is to be ignored when M1 = 0 (pin 11 is low). See 4.10 for an explanation of M (mode) dependency. Likewise the symbol for the open-collector output is shown to be affected by affecting input number 2, which is M2, meaning the \boxtimes label is valid when M2 = 1 (pin 11 is low), but is to be ignored when M2 = 0 (pin 11 is high). These labels are enclosed in parentheses (used as in algebra); the numeral 3 indicates that in either case the output is affected by EN3. Thus the right-hand outputs will be off if pin 1 is low. It can now be seen that pin 1 is the direction control and pin 11 is used to determine whether the outputs are of the 3-state or open-collector variety.

6.9 SN75161B Octal IEEE Std 488 Interface Bus Transceiver

There are eight I/O ports on each side, pins 2 through 9 and 12 through 19. Pin 13 is not only an I/O port; the line running into the common-control block (see Figure 2) indicates that it also has control functions. Pins 1 and 11 are also controls. The eight bidirectional channels each have amplification from left to right, that is, the outputs on the right have increased drive capability (indicated by \triangleright), and the inputs on the right all have hysteresis (indicated by \square). All of the outputs are shown to be of the 3-state type by the ∇ symbol except for the outputs at pins 9, 4, and 5, which are shown to have passive pullups by the \boxtimes symbol.

Starting with a typical I/O port, pin 18, the output portion is identified by an arrow indicating right-to-left signal flow and the three-state output symbol (∇). This output is shown to be affected by affecting input number 1, which is EN1, meaning it will be enabled as an output if EN1 = 1 (pin 11 is high). See 4.9 for an explanation of EN dependency.

If pin 11 is low, EN1 = 0 and the output at pin 18 will be in its high-impedance (off) state. This also applies to the 3-state outputs at pins 13 and 19 and to the passive-pullup output at pin 9. On the other hand, the outputs at pins 8, 2, 3, and 12 all are affected by the complement of EN1. This is indicated by the bar over the 1 at each of those outputs. They are enabled only when pin 11 is low. Thus one function of pin 11 is to serve as direction control for the first, third, fourth, and fifth channels.

Similarly it can be seen that pin 1 serves as direction control for the sixth, seventh, and eighth channels. If pin 1 is high, transmission will be from left to right in the sixth channel, right to left in the seventh and eighth. These transmissions are reversed if pin 1 is low.

The direction control for the second channel, EN3, is more complex. EN3 is the output of an OR (≥ 1) function. One of the inputs to this OR is the active-high signal on pin 13. This signal is shown to be affected at the input to the OR gate by affecting input number 5, which is G5, meaning that pin 13 is ANDed with pin 1 before entering the OR gate. See 4.2 for an explanation of G (AND) dependency. The other input to the OR is the active-low signal on pin 13. This signal is ANDed with the complement of pin 11 before entering the OR gate. This is indicated by the G4 at pin 1 and the 4 with a bar over it at pin 13. Thus for EN3 to stand at the 1 state, which would enable transmission from pin 14 to pin 7, both pins 13 and 1 must be high or both pins 13 and 11 must be low.

6.10 SN5520 Dual-Channel Sense Amplifier with Complementary Outputs

There are two input channels. The symbology is complete for the first channel; the absence of any symbology for the second channel indicates it is identical.

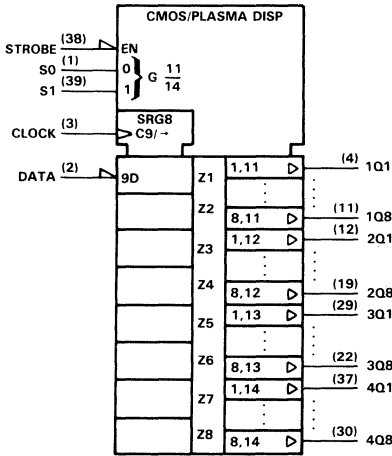

The square bracket around the input lines connected to pins 2 and 3 shows they constitute a single input pair. The $+/-$ by one line and the $-/+$ by the other indicate that these are differential inputs, and in this case, only the magnitude and not the polarity of the applied voltage affects the device. The differential inputs connected to pins 5 and 4 supply the reference voltage for both channels; see Figure 2 for an explanation of the common-control block. The differential input of each channel constitutes one input of an AND gate (indicated by &). The other input to the AND gate is pin 15 or 11. The outputs of the two AND gates go to an OR gate (indicated

by ≥ 1). Pin 14 is also an input to this OR gate and is shown by the ∇ symbol to be active when low. Thus if a voltage greater in magnitude than V_{ref} is applied to either channel along with a high-level voltage to the respective "S" input, or if pin 14 is low, then the output at pin 13 will be high.

Pin 12 is shown to be the complement of pin 13 except that pin 12 is shown by its label "1" to also be affected by pin 10 (G1) in an AND relationship. See 4.2 for an explanation of G (AND) dependency. Thus if pin 10 is low, it imposes the internal 0 state or external high level on pin 12.

Pins 5, 4, and 1 are all shown to be nonlogic connections by the small X superimposed on those lines. The function of such a connection is indicated briefly and not necessarily very exactly by a small amount of text within the symbol. Pin 1 is a connection for an external capacitor. The function of pins 5 and 4 was explained above.

6.11 SN75500E AC Plasma Display Driver with CMOS-Compatible Inputs

the internal labels and the pin numbers are both consecutive. Thus it should be clear that the input of the element whose output is pin 5 is affected by affecting input number 2, just as the input of the element whose output is pin 4 is affected by affecting input number 1. Affecting inputs 1 through 8 are Z inputs (Z1 through Z8), which means their signals are transferred directly to the output elements. See 4.6 for an explanation of Z dependency.

The inputs of the 32 implicitly shown output elements are also shown to be affected by affecting inputs numbers 11, 12, 13, and 14 in four blocks of eight each. These inputs will be found in the common control block preceded by a letter G and a brace. The brace is called the binary grouping symbol. It is equivalent to a decoder with outputs in this case driving four G inputs (G11, G12, G13, and G14). The weights of the inputs to the coder are shown to be 2^0 and 2^1 for pins 1 and 39, respectively. The decoder has four outputs corresponding to the four possible sums of the weights of the activated decoder inputs. If pins 1 and 39 are both low, the sum of the weights = 0 and G11 = 1. If pin 1 is low while pin 39 is high, the sum = 2 and G13 = 1 and so forth. G indicates AND dependency, see 4.2. Only one of the four affecting G inputs at a time can take on the 1 state. The block of eight output elements affected by that G input are enabled; the 0 state is imposed on the other 24 output elements and externally those output pins are low.

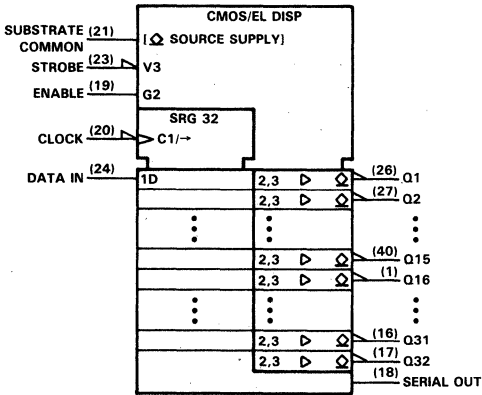

Because of their high-current, high-voltage characteristics, the outputs are labeled with the amplification symbol \triangleright . All the outputs share a common EN input, pin 38. See Figure 2 for an explanation of the common control block. When EN = 0 (pin 38 is high), the outputs take on their internal 0 states. Being active high, that means they are forced low.

The heart of this device and its symbol is an 8-bit shift register. It has a single D input, pin 2, which is shown to be affected by affecting input number 9, which is C9, meaning it will be enabled if C9 = 1. See 4.8 for an explanation of C dependency and 5.0 for a discussion of bistable elements. Since the C input is dynamic, the storage elements are edge-triggered flip-flops. While C9 = 1, which in this case will occur on the transition of pin 3 from low to high, the state of the D input will be stored. Pin 2 is shown to be active low so to store a 1, pin 2 must be low.

In addition to controlling the D input, pin 3 is shown by \rightarrow to have an additional function. As pin 3 goes from low to high, data stored in the shift register is shifted one position. The right-pointing arrow means that the data is shifted away from the control block (down).

On the right side of the symbol an abbreviation technique has been used that is practical only when

6.12 SN75551 Electroluminescent Row Driver with CMOS-Compatible Inputs

The heart of this device and its symbol is a 32-bit shift register. It has a single D input, pin 24, which is shown to be affected by affecting input number 1, which is C1, meaning it will be enabled if C1 = 1. See 4.8 for an explanation of C dependency and 5.0 for a discussion of bistable elements. Since the C input is dynamic, the storage elements are edge-triggered flip-flops. While C1 = 1, which in this case will occur on the transition of pin 20 from high to low, the state of the D input will be stored. Pin 24 is shown to be active high so to store a 1, pin 24 must be high.

In addition to controlling the D input, pin 20 is shown by /→ to have an additional function. As pin 20 goes from high to low, data stored in the shift register is shifted one position. The

right-pointing arrow means that the data is shifted away from the control block (down). The internal inputs of the output buffers are all shown to be affected by affecting inputs 2 and 3. Affecting input 2 is G2, meaning that pin 19 is ANDed with each of the internal register outputs, which are the buffer inputs. If pin 19 is high, the affected buffer inputs are enabled. If pin 19 is low, the 0 state is imposed on the affected buffer inputs. See 4.2 for an explanation of G (AND) dependency. Affecting input 3 is V3, meaning that pin 23 (active low) is ORed with each of the internal register outputs. If pin 23 is high, V3 = 0 and the affected buffer inputs are enabled. If pin 23 is low, V3 = 1 and the 1 state is imposed on the affected buffer inputs. See 4.4 for an explanation of V (OR) dependency. The effect of V3 is taken into account after that of G2 because of the order in which the labels appear. This means that the imposition of the 1 state on the internal buffer inputs by pin 23 would take precedence over the imposition of the 0 state by pin 19 in case both inputs were active. Pin 18 is shown to be an output directly from the thirty-second stage of the shift register. Pins 19 and 23 do not affect this output.

An abbreviation technique has been used for the shift register elements and associated the output lines. This technique is practical only when the pin numbers and pin names are both consecutive.

The symbol \square designates an n-p-n open-collector or similar output. In this device, the outputs are actually open-drain n-channel field-effect transistors. Instead of being grounded, the sources of these transistors are all connected to pin 21. This pin is used as an input to control the output voltage.
