1.1 MANUAL SCOPE

The PDP-11/24 System Technical Manual provides an explanation of the PDP-11/24 system as well as system installation, checkout, and troubleshooting information. The manual primarily explains the central processor operation. Although there is some component description, the manual does not detail the operation of all components in the system. For more details on individual components, the reader should refer to the appropriate manual(s) in the table of Related Documentation (Table 1-1).

1.2 SYSTEM OVERVIEW

A block diagram of a typical PDP-11/24 system configuration is provided in Figure 1-1. Most of the components and peripherals communicate with each other on the UNIBUS. The UNIBUS is a high speed bus which transfers addresses, data, and control information. An additional bus, Extended UNIBUS (EUB), is provided between the Central Processor and memory. The EUB allows for the rapid transfer of 22-bit address information between the Central Processor and memory. Each device, including memory locations, processor registers and peripheral device registers, is assigned an address on the UNIBUS. This allows all peripheral registers to be manipulated as easily as memory locations by the Central Processor.

1.3 PDP-11/24 CENTRAL PROCESSOR

Figure 1-2 provides a block diagram of PDP-11/24 central processor (KDF11-UA). The KDF11-UA is a hex width multi-layer module (8.5" x 15.0") which contains the following features:

- o Central Processor Base Machine
- o Memory Management Unit (MMU)
- o Floating Point Processor (FPP) option
- o Commercial Instruction Set Processor (CISP) option
- o Two Serial Line Interfaces (SLU)
- o Line Frequency Interrupt Real Time Clock
- o Extended UNIBUS (EUB)

The Central Processor base machine contains the Central Processor base machine hybrid, Data chip and Control chip mounted on one 40 pin package, as well as various other support logic contained on the module such as buffers and the PAX latch. The central processor base machine hybrid contains the PDP-11 register file, the ALU, and microprogram storage. The MMU chip contains all the logic necessary for address relocation as well as 16-bit working registers and 64-bit accumulators necessary for the execution of floating point instructions. The remaining floating point logic is contained on the floating point processor control hybrid. An additional hybrid containing 6 chips is used for the execution of CIS instructions. The two major buses which provide for the transfer of information within the CP are the Microinstruction Bus (MIB) and the Data/Address Lines (DAL).

MAJOR BUSSES SHOWN:

- 1. DAL COMMUNICATIONS BETWEEN CHIPS; COMMUNICATIONS TO EXTERNAL DEVICES
- 2. BDAL BUFFERED CHIP BUS
- 3. EUB EXTENDED UNIBUS A DIRECT 22-BIT ADDRESS PATH TO MEMORY
- 4. UNIBUS EXTERNAL BUS TO I/O DEVICES

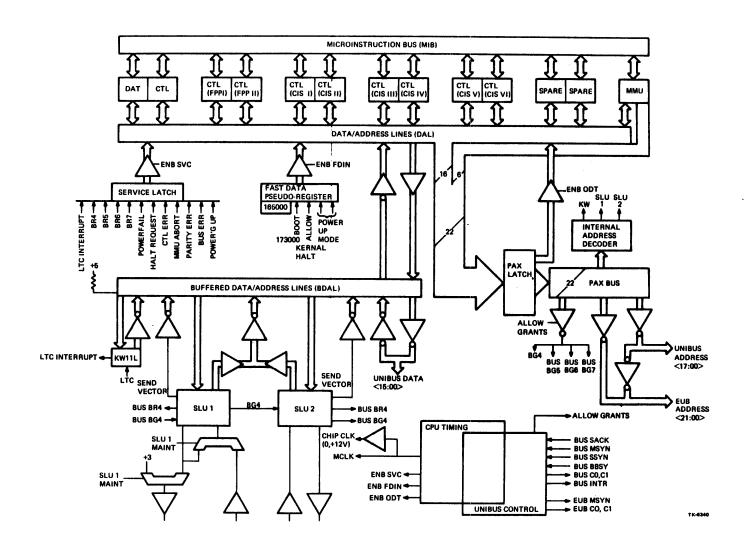

Figure 1-2 PDP-11/24 Central Processor

The MIB contains either control and status information or microinstructions from the control store. The DAL contains either Data/Address information or service information. The type of information present on the MIB and DAL is specified by the time state (Phase Time and Phase Bar Time) the CPU is in. A more detailed explanation of the CPU time states and internal buses is provided in Chapter 4. In addition to the MIB and DAL another information bus is included in the CPU. The BDAL (Buffered Data/Address Lines) is also used for the transfer of data/address information. It provides a buffered data/address bus which transfers information between the DAL, line time clock, serial line units and the Unibus. Each section of the CPU is explained in the following paragraphs.

1.3.1 CPU Data and Control Chips

The CPU Data Chip contains the PDP-11 register file, the ALU and conditional branching logic. The Data Chip performs all arithmetic and logical functions, handles all data/address transfers (except relocation) with the external busses and operates most of the signals used for interchip communication and external system control. The Control Chip contains the microprogram and most of the microcontrol logic used in the PDP-11/24. Both the CPU Data Chip and Control Chip are mounted on a single 40 pin multilayer ceramic hybrid IC.

1.3.2 Memory Management

The KDF11-UA central processor also contains a Memory Management Unit (MMU chip) which maps 16 bit virtual addresses to the appropriate 18 bit or 22 bit physical addresses. The mapping scheme takes place automatically and is transparent to the user. The MMU contains the necessary status registers and Active page registers (PAR/PDR register pairs) as well as access error detection capability. The MMU chip also contains the registers needed for storage of various information for floating point operations.

The memory management unit is useful in a multiprogramming environment. The processor can operate in two modes, kernel and user. When in the kernel mode, the program has complete control and can execute all instructions. Monitors and supervisory programs are executed in this mode. The user mode allows memory protection in a multi-user operating system. This prevents the program from executing instructions which could modify the kernel program, halt the computer or use memory space assigned to the kernel or to other users. Chapter 5 provides a complete description of the memory management system as implemented by the PDP-11/24.

1.3.3 Operator's Console

The operator's console provides the communication link between the user and the processor. Although the PDP-11/24 does not have the traditional "lights and switches" console, Octal Debugging Technique (ODT) exists as a portion of the microcode which allows

the processor to respond to commands and information entered via an ASCII terminal. The terminal emulates the capabilities found on "lights and switches" consoles. Communication between the user and the processor is via a stream of ASCII characters interpreted by the processor as console commands. Chapter 3 provides a detailed explanation of the console operations.

The actual PDP-11/24 console does however, have a minimum number of switches and lights which perform basic functions and provide some system status information. Chapter 3 provides an explanation of the PDP-11/24 operator's console.

1.3.4 Serial Line Units

The Serial Line Units (SLU1 and SLU2) provide two serial ASCII interfaces for the central processor. SLU1 is reserved for use by the system console. SLU1 may be used as a general purpose serial line unit. A typical application of this SLU is the connection of a TU58 DECtape II unit. The SLUs accept serial data from the console terminal and TU58, convert it to parallel data, and transfers the data onto the BDAL. The SLUs also accept parallel data from the BDAL for serial conversion and transfer to the console terminal and TU58. Both SLUs contain the registers necessary for data transfers. Section 4.6 contains a detailed explanation of the SLUs and their associated logic.

1.3.5 Line Time Clock

The Line Time Clock is contained on the central processor module and provides the system with timing information at fixed intervals of 16.7 msec (60Hz line) or 20.0 msec (50Hz line). The PDP-11/24 line time clock is KWll-L compatible except that the "ready" bit is automatically cleared when the LTC interrupts. Accuracy is dependent on the accuracy of the line frequency. When the interrupt mode is enabled an interrupt is generated for each cycle of the line frequency. When in the noninterrupt mode, a monitor bit in the status register is tested under program control. Each time the program notes that the bit has been set it must clear the bit and note the passage of time. A description of the line time clock is provided in Section 4.7.

1.3.6 Bootstrap

The PDP-11/24 contains either an M9312 Bootstrap/Terminator Module or the optional UNIBUS Map Module (M7134) which contains equivalent logic. Either module contains 512 words of read only memory (ROM) which can be used for diagnostic routines and bootstrap programs. Five sockets allow the user to interchange ROMs, enabling various peripheral devices to be bootstrapped. Diagnostics and the different bootstrap programs are selectable through the offset switch bank located on each module.

Bootstraps may be initiated in three ways:

- 1. Pressing the Boot Switch on the operator's console.
- System power-up (if enabled via jumper W2 on the CPU module).
- 3. Programmers console "load address and start" sequence (the programmer loads the starting address of a particular bootstrap routine).

Refer to the M9312 Bootstrap/Terminator Technical Manual for a complete description of the M9312. The UNIBUS Map Option (M7134) is described in Chapter 6 of this manual.

1.3.7 UNIBUS Termination

The UNIBUS is a transmission line and must be terminated at both ends. The CPU module provides the termination for one end of the UNIBUS and either the M9312 Bootstrap/Terminator Module (in versions of the PDP-11/24 without the optional UNIBUS Map Module) or an M9302 Terminator Module (in versions of the PDP-11/24 with the UNIBUS Map Option) must be installed at the other end of the UNIBUS to complete the termination.

1.3.8 MS11-L MOS Memory System

The MS11-L metal oxide semiconductor (MOS), random access memory (RAM) is designed to be used with the PDP-11 UNIBUS or special buses with additional addressing capability such as the 22-bit EUB used in the PDP-11/24. The MS11-L provides storage for 18-bit words (16 data bits and 2 parity bits). There are two versions of the MS11-L (Table 1-2) which differ only by the total memory capacity available on the module. The maximum memory capacity of the PDP-11/24 is determined by both the packaging of the system and the options installed (see Table 1-3).

The MS11-L consists of a single, hex-height module (M7891) that contains the UNIBUS interface, timing and control logic, refresh logic and a MOS storage array. The module also contains logic to generate and check parity, and a control and status register (CSR).

A complete description of the MS11-L MOS memory is provided in the MS11-L MOS Memory User's Guide.

1.3.9 Floating Point Processor

The KEF11-A Floating Point Processor (FPP) is a microcode option for the KDF11-UA processor. Floating point instructions supplement integer arithmetic instructions such as MUL and DIV which are contained in the standard PDP-11/24 instruction set. The FPP allows floating point operations to be executed 5 to 10 times faster than equivalent software routines as well as conserving memory space. Floating point instructions provide for both single precision (32-bit) and double precision (64-bit) operands. The PDP-11/24 FPP implements the same floating point

Table 1-2 MS11-L Versions

Option Designation	Module Designation	Storage Capacity
MS11-LB	M7891-BA	128KB (64KW X 18-bit)
MS11-LD	M7891-DA	256KB (128KW X 18-bit)

Table 1-3 Memory Capacity

Version of PDP-11/24	Maximum Capacity	Total Number of Memory Modules*
PDP-11/24 without KT24 option, mounted in BA11-L or BA11-A Box	256KB (128KW)	1
PDP-11/24 with KT24 option, mounted in BAll-L Box	768KB (384KW)	3**
PDP-11/24 with KT24 option, mounted in BA11-A Box	1024KB (512KW)	4

^{*}Based on MS11-LD.

^{** 3} modules maximum in any combination.

instruction set found on the PDP-11/34, 11/44, 11/70 and other PDP-11 processors. A complete description of the FPP and floating point instructions is provided in Chapter 7.

1.3.10 Commercial Instruction Set Processor

The KEF11-B Commercial Instruction Set Processor (CISP) is a microcode option for use with the PDP-11/24 processor. The CISP significantly extends the capability of the PDP-11/24 in the area of commercial data processing. The Commercial Instruction Set (CIS) is a series of instructions for manipulating byte strings and performing decimal arithmetic. These instructions provide improved COBOL performance, text editing and word processing capabilities. The KEF11-B is completely software compatable with the KE44-A CISP used with the PDP-11/44 processor. A complete description of the PDP-11/24 CISP is provided in Chapter 8.

1.4 GENERAL-PURPOSE REGISTERS

The data chip contains eight 16-bit general-purpose registers that provide for a variety of functions. These registers can serve as accumulators, index registers, autoincrement registers, autodecrement registers, or as stack pointers for temporary storage of data. Arithmetic operations can be freely mixed from general registers, memory locations or device registers. Figure 1-3 identifies the eight 16-bit general registers RØ through R7.

Registers R6 and R7 are dedicated. R6 serves as the hardware stack pointer (SP) and contains the location (address) of the last entry on the stack. Two stack pointers actually exist; the selection of which stack pointer is to be used is determined by the processor operating mode. Thus the Kernel and User programs have independent hardware stacks. Register R7 serves as processor's program counter (PC) and contains the address of the next instruction to be executed. It is normally used for addressing purposes only and not as an accumulator. Register operations are internal to the processor and do not require bus cycles (except for instruction fetch); all memory and peripheral device data transfers do require bus cycles and longer execution time. Thus, general registers used for processor operations result in faster execution times.

1.5 ADDRESSING MEMORY AND PERIPHERALS

The KDF11-UA processor uses 16-bit data paths throughout. These same data paths are also used to construct operand and instruction addresses. Octal notation is used to describe information on the data paths.

A word is divided into a high byte and a low byte as shown in Figure 1-4.

Word addresses are always even numbered. Byte addresses can be either even or odd numbered. Low bytes are stored at even numbered memory locations and high bytes at odd numbered memory locations. Thus, it is convenient to view memory in either of the ways shown in Figure 1-5.

The full 16-bit data path allows a program to specify operand addresses (i.e., virtual addresses) anywhere within a 64K byte range or 32K word range. This virtual address range is fixed by the instruction format and cannot be changed by the user.

For applications that require more than 32K words of physical address, such as multiprogramming and/or timesharing applications, the Memory Management Unit (MMU) makes additional addressing bits available. These bits allow up to 1920K memory words to be physically addressed by the processor. This additional addressing capability is part of the standard memory management within the KDF11-UA architecture. Use of more than 128KW of memory in the PDP-11/24 requires the optional UNIBUS Map Module to be installed.

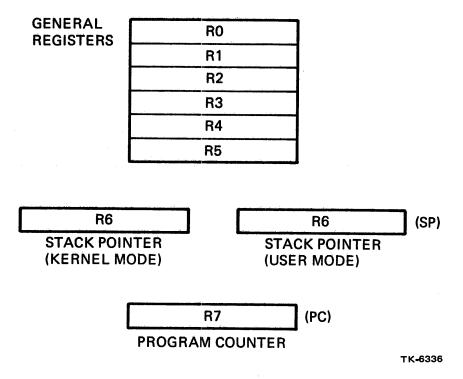

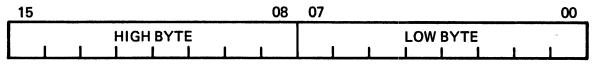

Figure 1-3 PDP-11/24 General Registers

TK-6337

Figure 1-4 High and Low Bytes

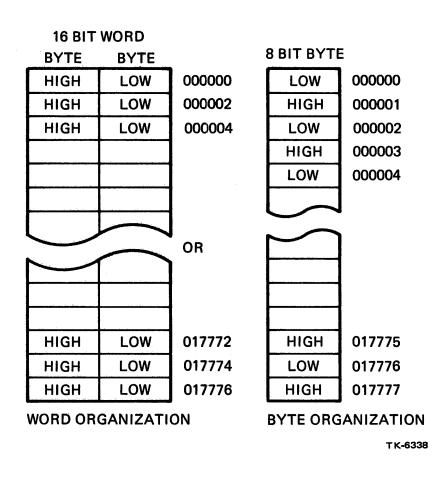

Figure 1-5 Word and Byte Addressing for the First 4K

1.6 ADDRESSING MODES

Much of the flexibility of the KDF11-UA is derived from its wide range of addressing capabilities. Addressing modes include sequential forward or backward addressing, address indexing, indirect addressing, absolute 16-bit word and 8-bit byte addressing, and stack addressing. Variable-length instruction formatting allows a minimum number of words to be used for each addressing mode. The result is efficient use of program storage space. For more details on addressing modes refer to the PDP-11 Processor Handbook.

1.7 INSTRUCTION SET

The KDF11-UA instruction set provides over 400 powerful instructions. As a comparison, consider that most other (i.e., accumulator-oriented) 16-bit processors require three separate instructions to execute a common double-operand instruction (e.g., ADD).

Conventional Approach:

LDA A Load contents of memory location A into accumulator.

ADD B Add contents of memory location B to accumulator.

STA B Store result at location B.

By contrast, the KDF11-UA can fetch both operands, execute, and store the result in one instruction.

KDF11-UA Approach:

ADD A, B Add contents of location A to location B; store results at location B.

This greater efficiency not only saves memory space and time, but also improves processor speed since fewer instruction fetches are required.

Another major advantage to the KDF11-UA instruction set is the absence of special-purpose input/output instructions. Special I/O instructions are unnecessary since peripheral device registers are accessed in the same way as main memory locations. This approach to handling I/O devices allows the normal instruction set to be used to test and/or manipulate the various I/O device register bits. For example, a compare instruction can test status bits directly in the I/O device register without bringing them into memory or disturbing any of the general registers; control bits can be set, cleared, or shifted as is most convenient; and peripheral data can be arithmetically or logically altered when received at the device register and before being stored in memory. Refer to PDP-11 Processor Handbook for a complete description of the instruction set and its utilization.

1.8 CONFIGURATION

The PDP-11/24 processor is contained in either the BA11-L [13.3 cm $(5\ 1/4\ inch)]$ mounting box or the BA11-A [26.67 cm $(10\ 1/2\ inch)]$ mounting box. Table 1-4 lists the basic processor configurations available. Table 1-5 lists the hardware options.

1.8.1 BAll-L Mounting Box

The BAll-L [13.3 cm (5 1/4 inch)] mounting box contains the PDP-l1/24 nine slot backplane with the system modules installed, and the H777-UA, -UB power supply and fans to provide cooling for the modules and power supply. A front bezel is attached to the front of the mounting box and contains the operator's control panel and ventilating slots to allow the entry of air.

1.8.2 BAll-A Mounting Box

The BAll-A [26.67 cm (10 1/2 inch)] mounting box contains the PDP-11/24 nine slot backplane with the system modules installed, the H7140-AA, -AB power supply and a fan assembly. The fan assembly contains three fans and provides cooling for the modules and power supply. A front bezel is attached to the front of the mounting box and contains the operator's control panel and ventilating slots to allow the entry of air. In addition to the PDP-11/24 backplane, the BAll-A mounting box has the space to mount an additional 4 system units of equipment. The system units may be backplanes for specific controllers (e.g., DH11, RH11, or RK611) or general purpose backplanes (e.g., DD11-CK or DD11-DK).

1.8.3 System Configurations

Three hardware configurations are available as packaged systems (Figure 1-6). Each system is available with a variety of software packages.

RX02 Packaged System - This system contains a PDP-11/24 in a 13.3 cm (5 1/4 in) BAll-L mounting box and a dual RX02 floppy disk unit providing 1 MB of storage. This system is packaged in a 101 cm (40 in) high, 54.29 cm (21.38 in) wide, 76.2 cm (30 in) long cabinet.

RL02 Packaged System - This system contains a PDP-11/24 in a 13.3 cm (5 1/4 in) BAll-L mounting box and two RL02 cartridge disk drives. This provides 20 MB of removable hard disk storage. This system is packaged in a 101 cm (40 in) high, 69.55 cm (27.38 in) wide, 76.2 cm (30 in) long cabinet.

RKØ7 Packaged System - This system contains a PDP-11/24 in a 26.67 cm (10 1/2 in) BAll-A mounting box and two RKØ7 cartridge disk drives. This provides 56 MB of online storage and the ability to incorporate 1 MB of main memory. Each unit is packaged in a 101 cm (40 in) high, 54.29 cm (21.38 in) wide, 76.2 cm (30 in) long cabinet.

Table 1-4 Basic Processor Configurations

Designation	Description
PDP-11/24-AA,-AB*	Contains a CPU, 128KB of MS11-L MOS Memory, M9312 Bootstrap and BA11-L mounting box.
PDP-11/24-AC,-AD*	Contains a CPU, 256KB of MS11-L MOS Memory, M9312 Bootstrap and BA11-L mounting box.
PDP-11/24-BC,-BD*	Contains a CPU, 256KB of MS11-L MOS Memory, M9312 Bootstrap and BA11-A mounting box.

^{*}The second designation is the 240 Vac version

Table 1-5 Hardware Options

O ption	Description

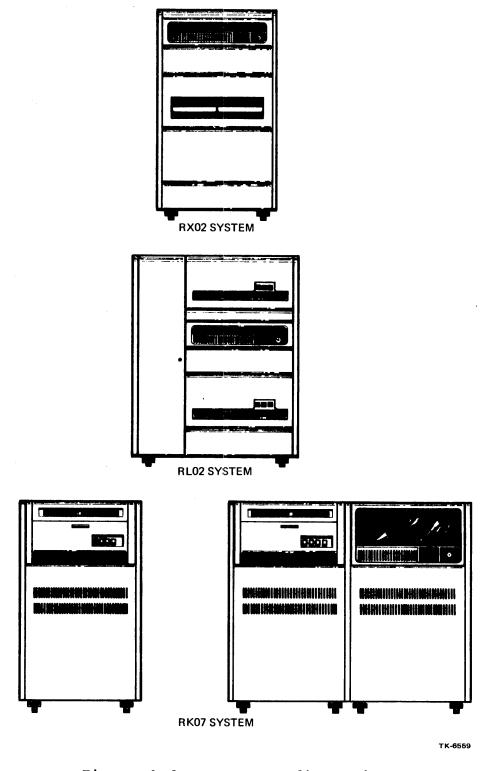

Figure 1-6 System Configurations

1.9 PDP-11/24 BACKPLANE

The PDP-11/24 backplane provides the electrical connections between the modules in the system. The PDP-11/24 processor must use its own backplane. The DD11-CK, -DK or -PK cannot be used to hold the PDP-11/24 processor module. The backplane consists of nine hex slots for module placement. The following guidelines must be followed for module placement (refer to Figure 2-21):

- o The CPU module (M7133) must be installed in slot 1.
- o M9312 Bootstrap/Terminator or UNIBUS cable must only be installed in slot 9.
- o NPR (DMA) options must be installed in slots 7 or 8. If installed in other slots, the NPG jumper wire from CAl to CBl must be removed.
- o Non-NPR options must be installed in slots 3, 4, 5, 6 or 9. If installed in other slots a wire must be added to carry NPG. This wire should connect CAl to CBl.
- o All empty slots, except slot 2, must have grant cards.
- o Slots 7 and 8 must have double-height grant cards (G7273) in rows C and D.

Slots 3, 4, 5, 6 and 9 may use single-height grant cards (G727A or G7270) in row D or double-height grant cards in rows C and D.

1.10 SPECIFICATIONS

Table 1-6 lists the specifications for the PDP-11/24. Tables 1-7 and 1-8 list the power (voltage and amps) supplied by the power supplies contained in the BAll-L and BAll-A mounting boxes. The voltages designated with a 'B' are memory voltages and are backed up by the optional battery back-up unit when it is installed in the system. Detailed specifications for peripheral devices supplied with these units are contained in the user's guide associated with the device.

Table 1-6 PDP-11/24 Specifications

Characteristic Desc	ription	
AC Power		
BAll-L Mounting Box:		
PDP-11/24-AA, -AC	104-127 Vrms, 47-63 Hz, 1 phase power, 5 amps rms maximum @ 120 Vac	
PDP-11/24-AB, -AD	208-258 Vrms, 47-63 Hz, 1 phase power, 2.5 amps rms maximum @ 240 Vac	
BAll-A Mounting Box:		
PDP-11/24-BC	90-128 Vrms, $47-63$ Hz, 1 phase power, 16 amps rms maximum at 120 Vac	
PDP-11/24-BD	180-256 Vrms, $47-63$ Hz, 1 phase power, 9 amps rms maximum at 240 Vac	
Mechanical		
Size:		
BA11-L	Box is 13.5 cm high X 42.21 cm wide X 69 cm deep (5.25" X 16.62" X 26"). The BAll-L mounts in a standard 48 cm (19") rack.	
BA11-A	Box is 26.3 cm high X 42.21 cm wide X 69 cm deep (10.35" X 16.62" X 25"). The BAll-A mounts in a standard 48 cm (19") rack.	
Weight		
BA11-L	20 Kg (45 lbs.)	
BA11-A	32 Kg (70 lbs.)	
Operating Environment		
The BAll-L and BAll-A mounting boxes with PDP-11/24 CPU have the same operating and non-operating environment specifications.		
Temperature	5° C to 50° C (41° F to 122° F)	

Table 1-6 PDP-11/24 Specifications (Cont)

Characteristic	Description
Humidity	10% of 95% with a maximum wet bulb of 32° C (89.9°F) and a minimum dew point of 2° C (36° F)
Altitude	to 2.4 Km (8000 ft.)
Non-Operating Environmen	t
Temperature	-40° C to 80° C (-40° F to 176° F)
Humidity	to 95% (noncondensing)

$$I_{+5} = 120 - 5 (I_{+15} - 1) - 5 (I_{-15} - 1)$$

2.1 GENERAL

This chapter provides the information necessary for site preparation, unpacking, inspection, and first-time start-up of the basic PDP-11/24 system.

2.2 SITE CONSIDERATIONS

The computer room environment should have an air distribution system that provides cool, well-filtered, humidified air. The room air pressure should be kept higher than that of adjacent areas to prevent dust infiltration.

Computer area environment can have a substantial effect upon the overall reliability of the system. Temperature cycling and thermal gradients induce temporary or permanent microscopic changes in materials that can affect performance or endurance. High temperatures tend to increase the rate of deterioration for nearly every material. High absolute humidity (dew point) causes moisture absorption that can result in dimensional and handling changes in paper and plastic media (line printer paper, cards, paper tape, magnetic tape, etc.)

Low humidity allows static electricity to build up, while lack of air cleanliness results in dust that reduces tape life and leads to excessive head wear and early data errors in all moving magnetic storage media (tapes and disks). This combination of static electricity and airborne dust is especially detrimental to magnetic tapes.

Vibration can also cause slow degradation of mechanical parts and, when severe, may cause errors on disks and tapes.

Hardware errors can also be caused by electromagnetic interference (EMI). EMI sources that have been known to cause failures include: radar installations, lightning strikes, power transmission lines, vehicle ignition systems, broadcast transmitters, arc welders, etc.

2.2.1 Humidity and Temperature

The PDP-11/24 system is designed to operate in a temperature range of 5°C (41°F) to 50°C (122°F) at a relative humidity of 10 to 95 percent, as long as no condensation occurs. In system configurations that use magnetic tape units, card readers, disks, etc., refer to the appropriate manual for their specifications. Nominal operating conditions for a system configuration are a temperature of 20°C (70°F) and a relative humidity of 45 percent.

2.2.2 Air-Conditioning

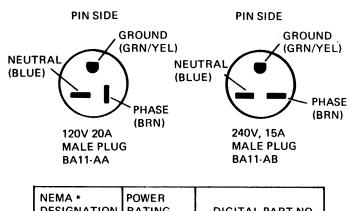

When used, computer room air-conditioning equipment should conform to the requirements of the Standard for the Installation of

Air-Conditioning and Ventilating Systems (Non-Residential) N.F.P.A. No. 90A, as well as the requirements of the Standard for Electronic Computer Systems, N.F.P.A. No. 75.

- 2.2.3 Acoustical Damping
 Some peripheral devices (such as line printers and magnetic tape transports) are quite noisy. In installations that use a group of high noise level devices, an acoustically damped ceiling will reduce the noise.
- 2.2.4 Lighting
 If CRT peripheral devices are part of the system, the illumination surrounding these peripherals should be reduced to enable the operator to conveniently observe the display.
- 2.2.5 Special Mounting Conditions
 If the system will be subjected to rolling, pitching, or vibration of the mounting surface (e.g., aboard ship), the cabinetry should be securely anchored to the installation floor by mounting bolts. Since such installations require modifications to the cabinets, DEC must be notified when the order is placed so that the necessary modifications can be made.
- 2.2.6 Static Electricity
 Static electricity can be an annoyance to operating personnel and can (in extreme cases) affect the operational characteristics of the PDP-11/24 system and related peripheral equipment. If carpeting is installed on the computer floor, it should be of a type designed to minimize the effects of static electricity. Flooring consisting of metal panels, or flooring with metal edges, should be adequately grounded.
- 2.3 ELECTRICAL REQUIREMENTS
 The PDP-11/24 system can be operated from a 120/240 Vac, 47 to 63
 Hz power source. The primary ac operational voltages should be within the defined tolerances. The primary power outlets at the installation site must be compatible with the PDP-11/24 primary power input connectors. Refer to the related BA11-L or BA11-A mounting box manual for details concerning power requirements.

The types of connectors used with the PDP-11/24 depends on the mounting box (BA11-A, BA11-L) or cabinet configuration and whether the system is configured for 120 Vac or 240 Vac operation. Figure 2-1 shows the connectors used with the BA11-A and BA11-L mounting boxes. Figure 2-2 shows the connectors used on the 874-D, E Power Controller.

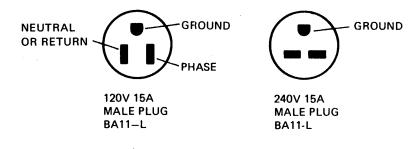

2.3.1 System Grounding
The PDP-11/24 3-prong power connector, when inserted into a properly wired receptacle, grounds the computer chassis. It is unsafe to operate the computer unless the case is grounded because

normal current leakage from the power supply flows to the metal parts of the chassis. If the integrity of the ground circuit is questionable, the user is advised to measure the potential between the computer case and a known ground with a voltmeter, or to notify your Field Service representative.

Computer systems are often sensitive to the interference present on some ac power lines. If the computer is to be installed in an electrically noisy environment, it is necessary to provide primary power to the computer on a separate power line from lighting, air-conditioning, etc., so that computer operation is not affected by voltage surges or fluctuations.

2.4 UNPACKING

The system equipment, associated devices, and cabinets are packaged and shipped in reinforced cartons and are protected internally by foam inserts and polyethylene bags. Accessories and supplies such as documentation, magnetic tape or disks connecting cables and hardware are packaged in separate containers. Before unpackaging any carton, remove the packing list from the container and check to ensure that the items ordered are listed. When the items are unpackaged, use the list to check that all the items are contained in the package. The unpacking information for consoles, printers, disk drives and magnetic tape is contained in the user's quide supplied with each device.

NOTE

Retain the packaging materials and shipping containers in the event that reshipping is required.

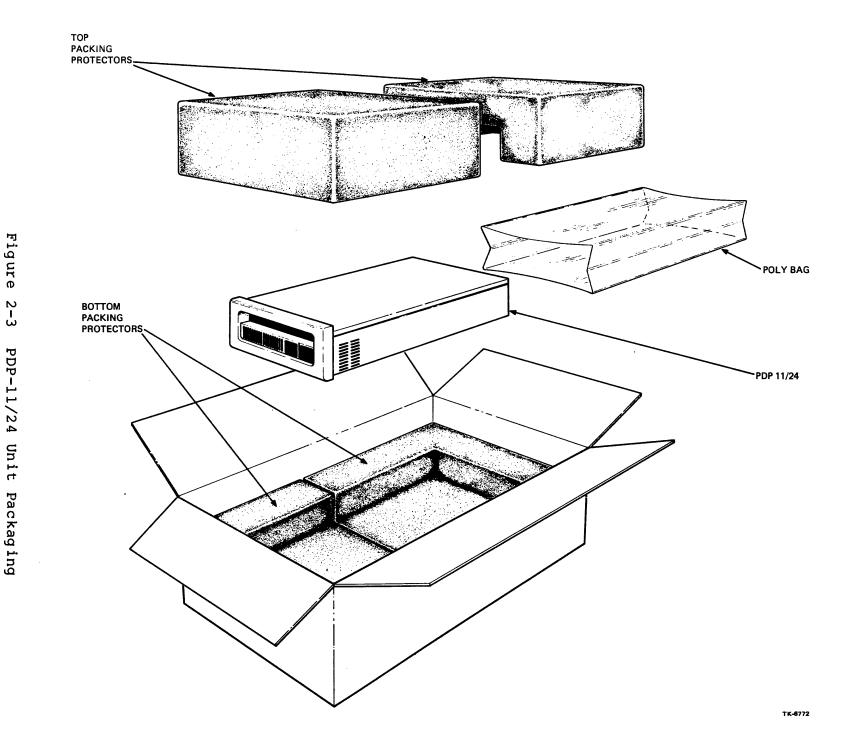

2.4.1 PDP-11/24-AA,AC,BC Unit Removal

The units are packaged in reinforced cartons and are protected by foam inserts and by a polyethylene bag as shown in Figure 2-3. To remove the unit from the container, perform the following procedure.

CAUTION

The PDP-11/24-BC unit weighs approximately 34 kg (75 lbs). Use care when lifting the unit from the carton.

- Open the leaves of the outer carton by cutting the tape at the seams.
- 2. Remove the inner carton from the foam protector.
- 3. Open the leaves of the inner carton by cutting the tape at the seams.
- 4. Remove the two (2) top protectors.

- 5. Remove the unit from the box.
- 6. Remove the unit from the polyethylene bag.
- 7. Inspect the unit for visible damage and to ensure that the contents are complete.

2.4.2 PDP-11/24 System Cabinet Removal

The PDP-11/24 system cabinets are attached to a wooden base, covered with a polyethylene bag and enclosed by a carton as shown in Figure 2-4. To remove the unit, perform the following procedures.

- 1. Cut the polyester straps used to secure the carton to the base.
- 2. Slide the carton up and away from the cabinet.
- 3. Remove the polyethylene bag from the cabinet.
- 4. Remove the bolts that hold the the wooden base to the bottom of the cabinet.
- 5. Remove the cabinet from the wooden base and set the cabinet in its operating location.

2.5 INITIAL INSPECTION

After unpacking the computer extend the wire frame assembly containing the logic and power subassemblies for the BAll-L (5 1/4") mounting box or remove the top and bottom covers on the BAll-A (10 1/2") mounting box. Examine the following areas:

- Check the overall appearance for scratches, dents, chipped paint, dust, etc.
- Check for loose or missing hardware (i.e., screws, nuts, etc.).
- 3. Toggle the front panel switch and operate the keyswitch to make certain they operate freely and are unrestricted.
- 4. Examine the backplane for bent pins.
- 5. Check the power and console harness for proper connection to the power supply and front console.

2.6 INSTALLATION

2.6.1 BAll-L Installation

The BAll-L mounting box is designed to be installed in a standard

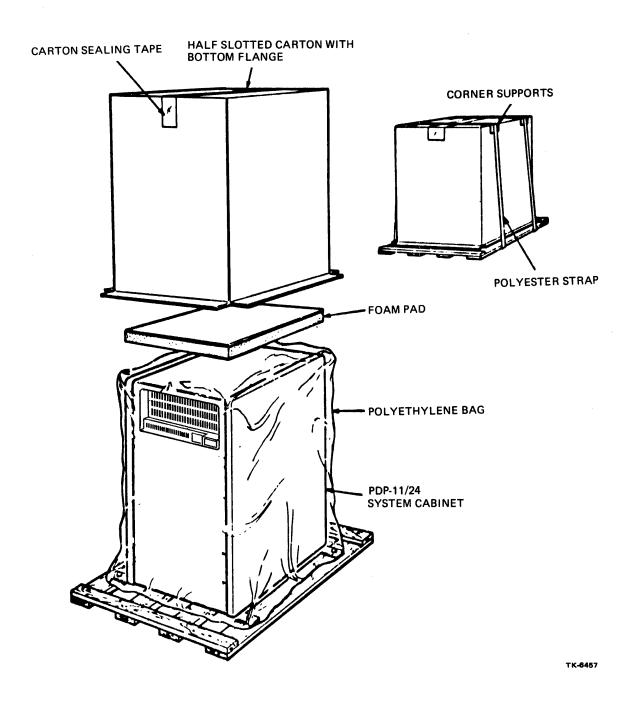

Figure 2-4 PDP-11/24 System Cabinet Unpacking

48.26 cm (19 inch) rack or cabinet using its own integrated mounting envelope/slider assembly (Figure 2-5).

To install the BAll-L box, perform the following steps:

- 1. Remove all shipping brackets.
- 2. Remove the mounting frame (Figure 2-5) from the mounting envelope. This is done by pulling the mounting frame forward until the safety catches are engaged. When the safety catches are engaged, press in on the locking tabs located on both sides of the mounting frame and remove the frame from the mounting envelope.
- 3. Locate and install the mounting envelope in the rack or cabinet as shown in Figure 2-6, using the 10-32 screws and KEP nuts supplied with the unit.
- 4. Slide the mounting frame into the mounting envelope. The safety catches must be pressed in so the wire frame can be inserted in to the mounting envelope.
- 5. Attach the ground lead from the mounting frame to the rack or cabinet rail.

2.6.2 BAll-A Installation

The BAll-AA,-AB mounting box is designed to be installed within a standard 48.26 cm (19 inch) rack or cabinet on slide mounting assemblies as shown in Figure 2-7.

A slide kit is available (part number 12-16971) and includes one each of the following items: left and right index plates and mounting hardware; left and right slide assembly and mounting hardware; and a BAll-A top cover.

The index plates supplied with the kit are to be mounted onto the sides of the BAll-AA,-AB mounting box and permit the box to be tilted on the slides for servicing.

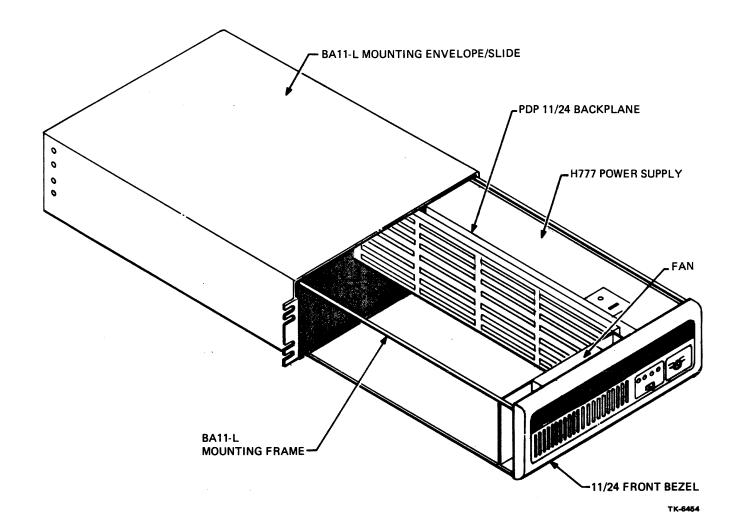

- 2.6.2.1 Index Plate Mounting -- To install the index plates refer to Figure 2-8 and perform the following procedures.
 - Position the right index plate onto the pawl as shown. The index plate mounting tab protrudes away from the side of the box.
 - 2. Insert the pivot screw and tighten with a screwdriver.
 - 3. Ensure that the index plate rotates freely when the locking pawl is released.
 - Perform steps 1 through 3 for the left index plate.

NOTE:

SLIDE AND SLIDE INDEX PLATE ARE USED WITH RACK MOUNTED VERSION.

Figure 2-7 BAll-A Mounting Box in H961 Cabinet

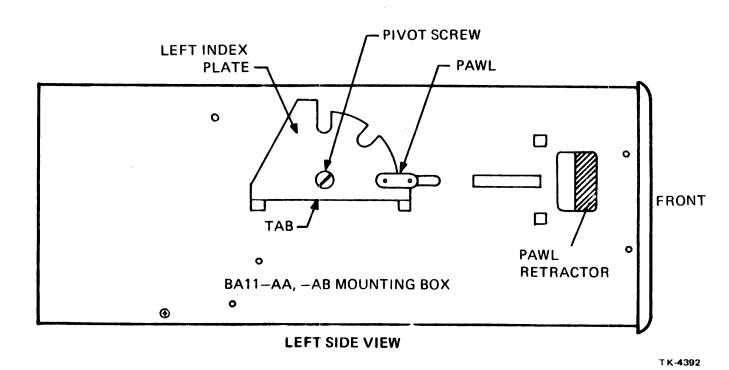

Figure 2-8 BAll-AA, -AB Mounting Box Index Plate Installation

2.6.2.2 Slide Assembly Mounting -- One of two types of slide assemblies is provided with the slide kit option: a single-channel slide set or a double-channel slide set. Figure 2-9 shows each type mounted to the BAll-AA, -AB unit and fully extended from the cabinet. The mounting location of the slides will vary depending on the type of slide. Figure 2-10 shows a typical H961 standard cabinet with the PDP-11/24-BC,-BD unit. The mounting location holes of the single-channel slides for each 26.67 cm (10.5 inch) unit are indicated in Figure 2-10. When installing double-channel slides, the hole location numbers will be decreased by two for the same mounting position of the units.

Figure 2-11 shows the hardware and installation of a single-channel slide assembly. The double-channel slide assembly is mounted in a similar manner. To install the slide assembly perform the following procedures.

- Position the left slide against the left front and left rear cabinet rail as shown.
- 2. Insert one 10-32 screw and washer through the top hole in the slide bracket, through the hole in the front rail and into the top threaded hole in the nut plate. Do not tighten.
- 3. Perform the same procedures in step 1 and step 2 at the left rear rail of the cabinet.
- 4. Insert one 10-32 screw and washer through the second hole from the bottom in the slide bracket, through the hole in the front rail and into the nut plate. Tighten both screws in the front rail.
- 5. Perform the same procedure in step 4 at the left rear rail of the cabinet.
- 6. Perform steps 1 through 5 to install the remaining slide onto the right side of the cabinet.

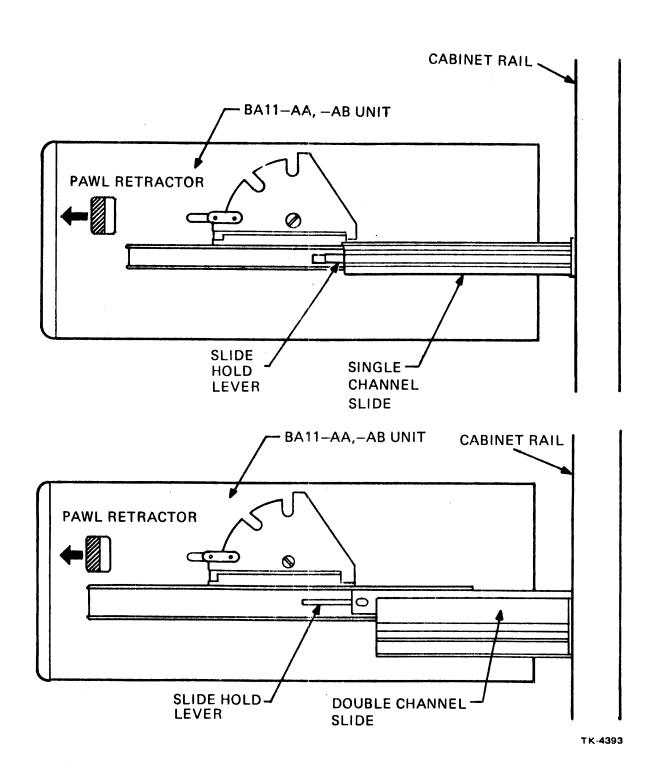

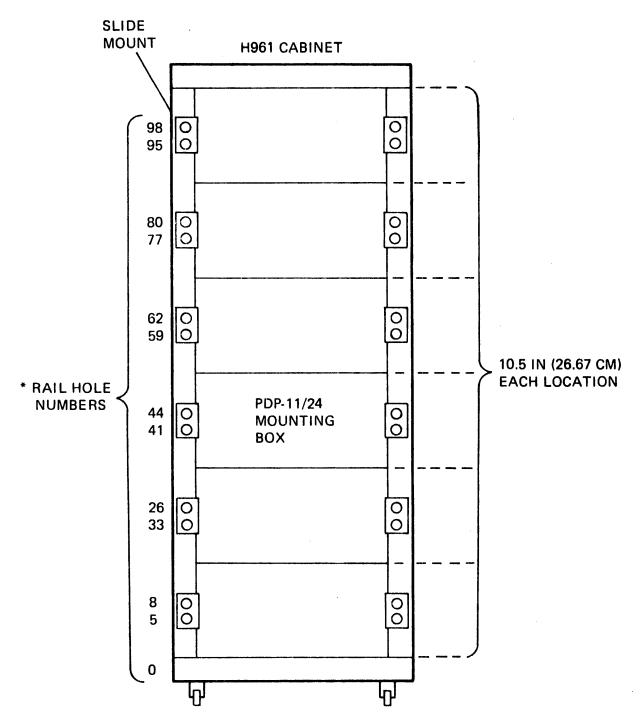

Figure 2-9 Single- and Double-Channel Slide Assemblies

* NOTE:

SINGLE CHANNEL SLIDE HOLE NUMBERS ARE SHOWN.
DECREASE RAIL HOLE NUMBERS
BY TWO (2) WHEN INSTALLING
A DOUBLE CHANNEL SLIDE SET.

Figure 2-10 H961 Cabinet Slide Mounting Locations

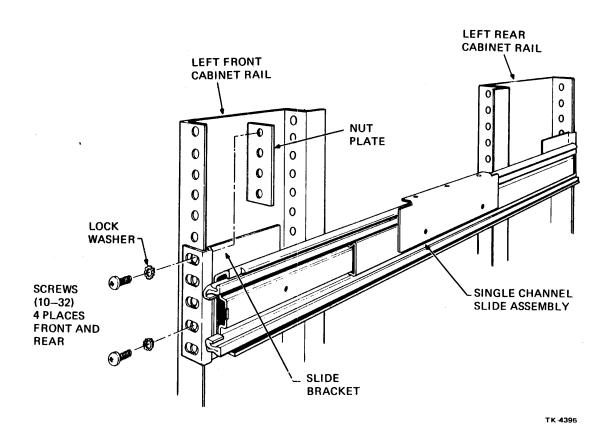

Figure 2-11 Cabinet Slide Installation

- 2.6.2.3 Mounting Box to Slide Installation -- Figure 2-12 shows the method and hardware used to install the mounting box onto the slide mounting bracket. Perform the following procedures.
 - 1. Extend the left and right slide channels to their maximum position at the front of the cabinet. When fully extended, the channels will be held in place by the slide hold lever shown in Figure 2-9.
 - Carefully lift the mounting box over and above the extended slides and set the index plate over the slide mounting bracket on each side of the box. The index plate alignment tabs will engage the sides of the slide mounting brackets.

NOTE

When the slides are fully extended, it may be necessary to force the ends of the slides inward toward the sides of the mounting box.

- 3. Insert the three 8-32 screws through the left index plate tab and into the threaded holes of the slide mounting bracket.
- 4. Perform the same procedure in step 3 for the right index plate.
- 2.6.3 PDP-11/24 System Cabinet Installation
 The PDP-11/24 System Cabinet is supplied with four rollers on the bottom frame and four leveler feet. The cabinet can be positioned alone or attached to another H9640 series cabinet. To install the PDP-11/24 System Cabinet, perform the following steps:
 - 1. Roll the system cabinet into position.
 - 2. Open the rear door of the cabinet. Use a 4 mm (5/32 inch) hex wrench to release the door fastener (Figure 2-13).
 - 3. Remove the ground wire connected between the door and the cabinet frame.
 - 4. Slide the retractable hinge pin down until the top of the door is released.
 - 5. Tilt the top of the door away from the cabinet and lift the door until the lower hinge pin is removed from the hole in the lower right bracket.
 - 6. Remove the rear door.

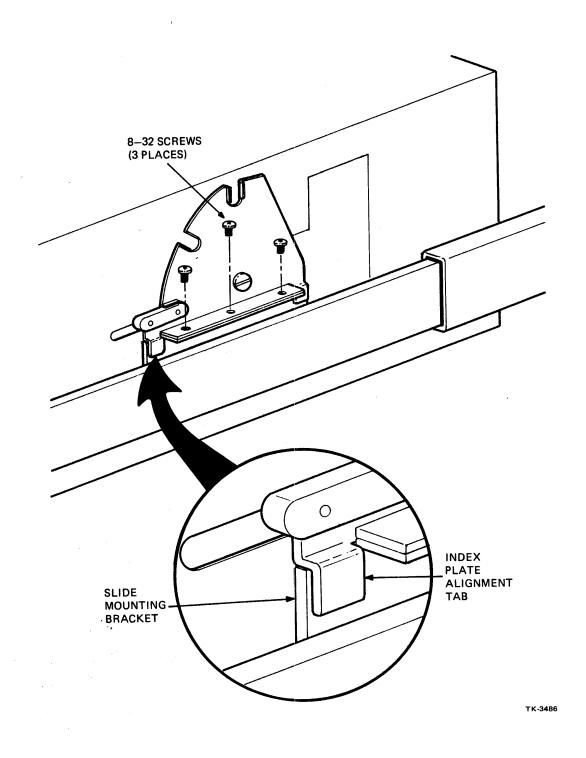

Figure 2-12 Mounting Box to Slide Installation

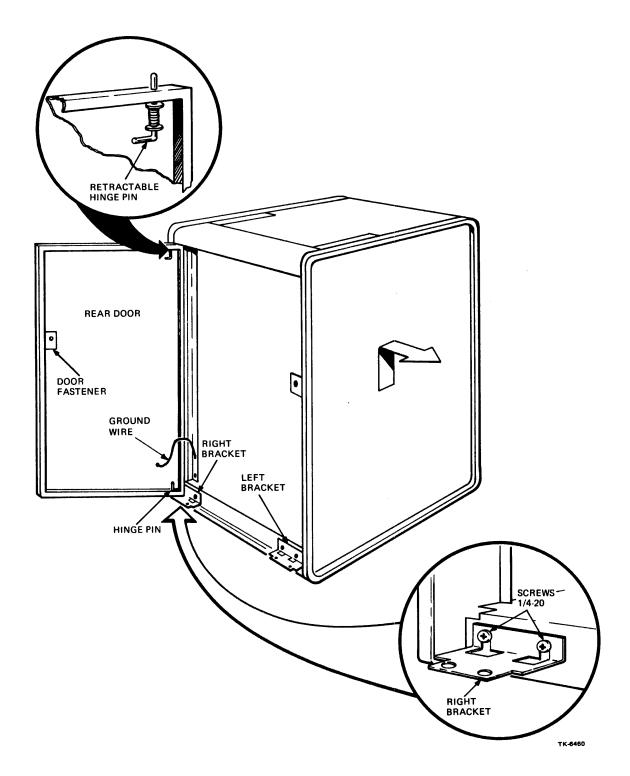

Figure 2-13 Left and Right Side Panel Removal

7. Remove the shipping brackets supplied with the devices mounted in the cabinet. Shipping brackets are painted orange. If the system contains RL02's make certain the black bracket attached to the top unit is not removed.

NOTE

Retain all shipping brackets in the event reshipping is required.

- 8. Loosen the two 1/4-20 screws and washers that attach the right and left brackets to the cabinet frame.
- 9. Remove and retain the right and left brackets.
- 10. Remove the left and right side panels by grasping each panel by the ends at the front and back of the cabinet and lifting the panel up approximately 2.5 cm (l in.) to disengage the panel. Pull the panel away from the cabinet to remove it and disconnect the ground wire attached to each panel.
- 11. Install the leveler feet supplied with the cabinet (see figure 2-14) by performing the following steps:
 - a. Screw a locking nut onto each leveler foot.
 - b. Screw each (4) leveler foot into a leveler nut.
 - c. Slide each nut and leveler foot assembly into a slot located at each corner of the cabinet base.
- 12. Install the stabilizer bar supplied with the cabinet (see Figure 2-15) by performing the following steps:
 - a. Screw a leveler foot into the stabilizer bar.
 - b. From the back of the cabinet, insert the stabilizer arm into the channel located on the bottom of the cabinet.
 - c. Remove the retaining cable and screw from the back of the cabinet base and attach the retaining cable to the underside of the stabilizer arm.

NOTE

The retaining cable is used to limit the forward extension of the stabilizer arm.

13. If an additional expander cabinet is a part of the system, it should be attached to the system cabinet at this time. Refer to Paragraph 2.6.3.1 for instructions.

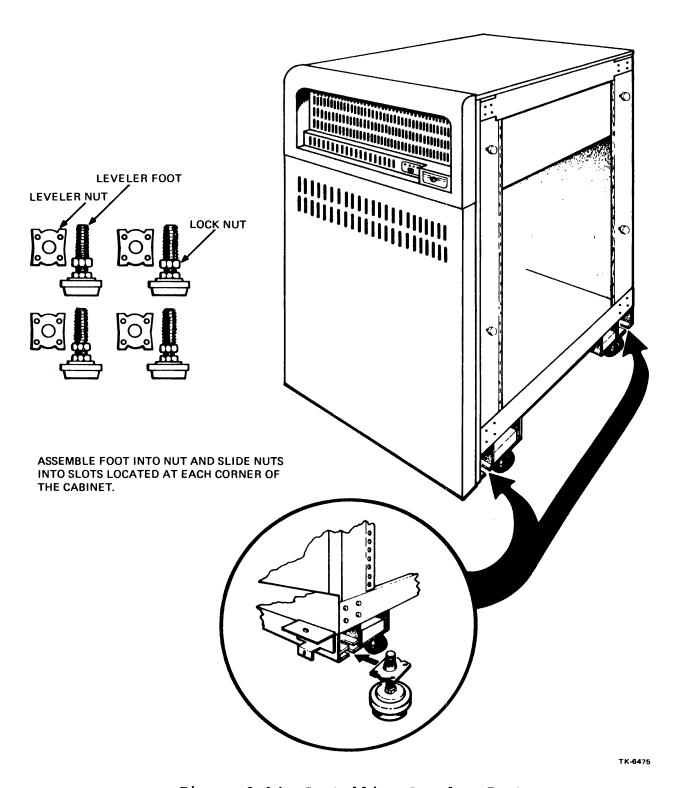

Figure 2-14 Installing Leveler Feet

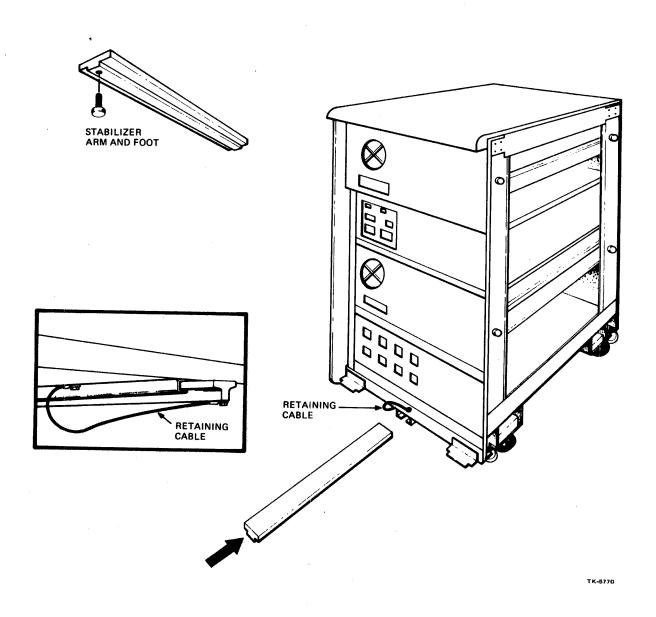

Figure 2-15 Stabilizer Arm Installation

- 14. Reconnect the ground wires and then replace the left and right side panels that were removed in step 10.
- 15. Replace the brackets that were removed in steps 8 and 9 and tighten the 1/4-20 bolts.
- 16. Tilt the rear door and insert the lower hinge pin into the lower right bracket.
- 17. Move the top of the rear door toward its mounting position while holding the retractable hinge pin down.
- 18. Release the retractable hinge pin when the pin is aligned with the hole in the top of the cabinet frame.
- 19. Reconnect the ground wire to the cabinet frame.
- 20. Close the rear door of the cabinet.
- 21. With the cabinet(s) in final position, adjust the leveler feet (Figure 2-16) on all cabinets for contact with the floor to prevent movement and then tighten the lock nut on each foot. Adjust the leveler foot on each stabilizer arm for smooth sliding contact with the floor.
- 22. Installation of terminals and peripheral devices (disc drives, tape drives, printers, etc.) should be done at this time.
- 2.6.3.1 Expander Cabinet Installation -- The following steps should be performed when joining H9640 series cabinets.
 - Perform Steps 3 through 6 and Steps 8 and 9 of paragraph
 2.6.3 for both the system cabinet and add-on cabinet.
 - 2. Remove the left side panel on the system cabinet by grasping the panel by the ends at the front and back of the cabinet and lift up approximately 2.5 cm (1 inch) to disengage the panel. Pull the panel away from the cabinet to remove it. Disconnect the ground wire from the panel.
 - 3. Remove the expansion panel from the add-on cabinet and install on the system cabinet by positioning the panel over the key buttons as shown in Figure 2-17. Drop panel in place.
 - 4. Remove the left side panel from the add-on cabinet.
 - 5. Install the leveler feet supplied with the add-on cabinet (see Figure 2-14) by performing the following steps:
 - a. Screw a lock nut onto each leveler foot.
 - b. Screw each (4) leveler foot into a leveler nut.

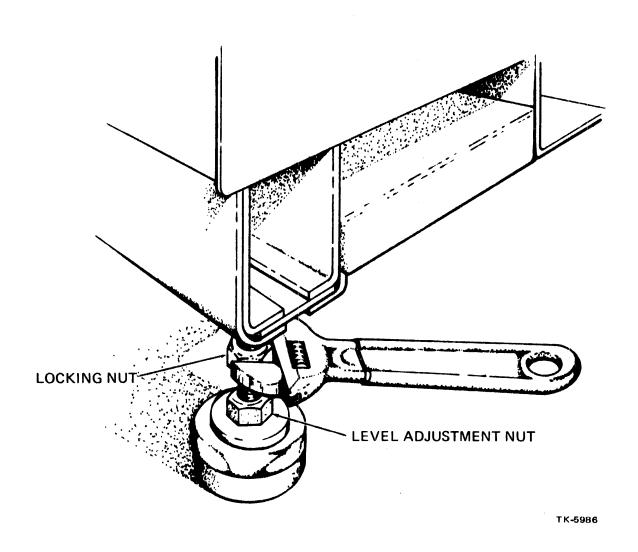

Figure 2-16 Leveler Feet Adjustment

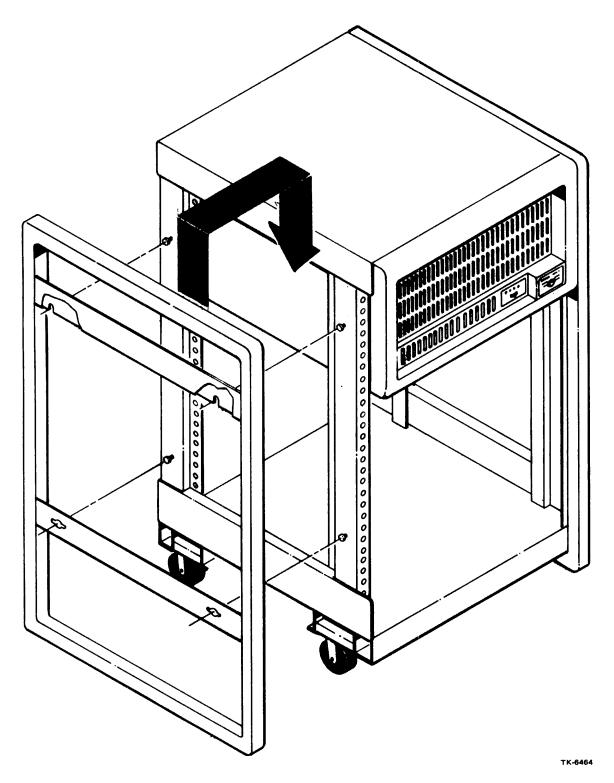

Figure 2-17 Add-On Panel Installation

- c. Slide each leveler foot and nut assembly into the appropriate slot located at each corner of the base.
- 6. Install the left side panel removed in Step 4.
- 7. Position cabinets as shown in Figure 2-18.
- 8. Engage top rear key button of the expansion cabinet in the key slots of the expansion panel.
- 9. Push cabinets together to engage the front top key button as shown in Figure 2-18.
- 10. Pull the expansion cabinet forward to lock the key buttons in the key slots.
- 11. Remove the front door and bottom front filler panel on each cabinet by performing the following steps:
 - a. If the cabinet has a front door it is removed in the same manner as the back door of the unit. Refer to steps 2 through 6 of paragraph 2.6.3.
 - b. If the cabinet has a bottom front filler panel this panel is removed by removing the two screws located at the bottom of the panel and then removing the panel. Disconnect any ground wire.
- 12. Bolt cabinets together at the bottom front of the cabinets by sliding the interconnecting bar behind the front edge of the expander panel as shown in Figure 2-19. Install screws and tighten.
- 13. Bolt cabinets together at the bottom rear of the cabinets: place the interconnecting bar over the hinge/end panel locking brackets as shown in Figure 2-20. Position screws and tighten.
- 14. Replace any doors or filler panels that were removed by performing the following steps:
 - a. If a door was removed perform steps 16 through 20 of paragraph 2.6.3.
 - b. If a filler panel was removed, put the panel back in place and install the screws removed in step 11b.
- 15. Perform steps 14 through 20 of paragraph 2.6.3 for the add-on cabinet.
- 2.6.3.2 Stabilizer Installation -- When the PDP-11X24 system cabinet (BAll-A) does not have another cabinet attached to it, a stabilizer bar (option no. H9544-MJ) must be attached to the rear

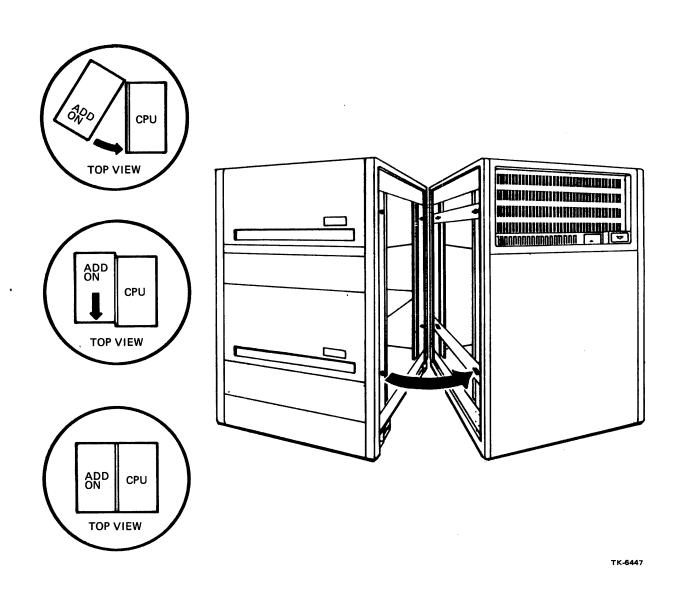

Figure 2-18 Joining Cabinets

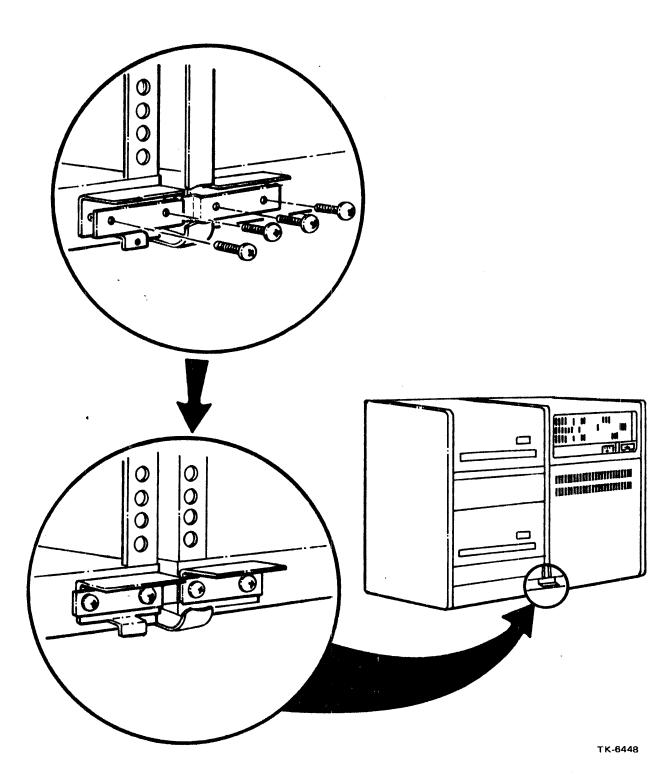

Figure 2-19 Front Interconnecting Bar

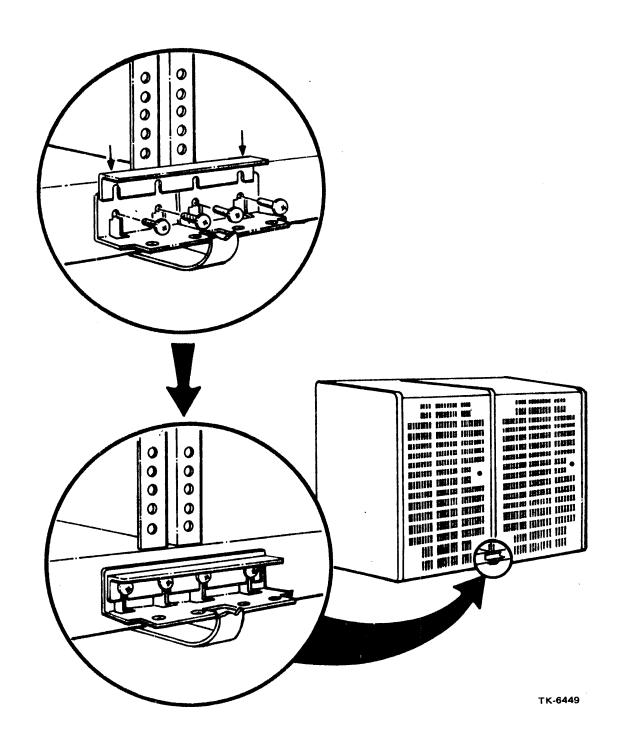

Figure 2-20 Back Interconnecting Bar

of the unit to prevent the cabinet from tilting to the side when the BAll-A box is raised to the service position.

Figure 2-21 shows the mounting position and hardware used to install the base stabilizer to the PDP-11X24 system cabinet. To mount the stabilizer, perform the following steps:

- 1. Position the left and right coupler over the collars on the base stabilizer as shown.
- 2. Slide the stabilizer under the rear of the cabinet to its normal mounting position.
- 3. Insert the mounting screw and washer, through the plate, through the slot in the frame, and into the threaded hole of the coupler. Do not tighten.
- 4. To level the cabinet, turn the coupler by inserting the shank of a screwdriver through the hole, in the direction desired.
- 5. Insert the shim into the location as shown.
- 6. Tighten the mounting screw with a 2 cm (13/16 inch) box-end wrench while holding the coupler in posititon with the screwdriver.
- 2.7 MODULE UTILIZATION IN A TYPICAL SYSTEM The PDP-11/24 processor module uses its own backplane (PN 70-16905) and can not use a DD11-CK, DD11-DK, or DD11-PK. Figure 2-22 shows the module utilization of the PDP-11/24 processor backplane.
 - o M9312 Bootstrap/Terminator Module or UNIBUS cable must only be installed in slot 9.
 - o NPR (DMA) options must only be installed in slots 7 or 8.
 - o Non-NPR options must only be installed in slots 3,4,5,6, or 9.
 - o All empty slots except slot 2, must have grant cards. Slots 7 and 8 must have a double height grant card (G7273) in rows C and D.

Slots 3, 4, 5, 6, and 9 may use a single height grant card (G727A or G7270) in row D or a double height grant card in rows C and D.

2.8 MODULE JUMPER AND SWITCH CONFIGURATIONS

2.8.1 CPU Module (M7133)
The CPU Module contains two switch packs and 14 jumper leads.

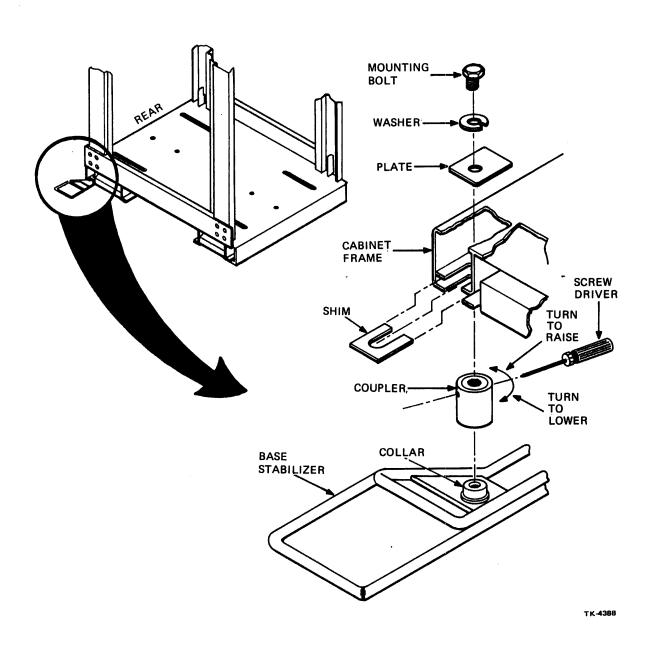

Figure 2-21 Cabinet Stabilizer Mounting

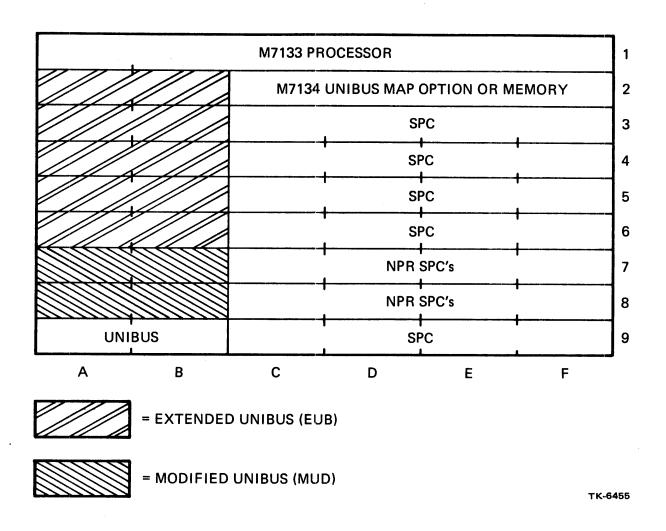

Figure 2-22 PDP-11/24 Module Utilization

Figure 2-23 shows the location of the jumpers and switches contained on the CPU module. Table 2-1 lists the function of the jumper leads. With the exception of E124 S5 and S6, the two swtich packs are used to configure the Serial Line Units. S5 of E124 when ON enables the field service maintenance mode on SLU1. This allows the looping of the received data back to the transmitter via the parallel data bus. When OFF, normal SLU operation is enabled. S6 of E124 is used to determine UNIBUS addressing: When ON, S6 allows just the top 128K addresses to go to the UNIBUS. When OFF, the lower 18 bits of every address go to the UNIBUS.

Serial Line Units (SLU) -- The PDP-11/24 CPU Module contains two serial line units. Serial Line Unit 1 (SLU1) is used by the console terminal. Serial Line Unit 2 (SLU2) is a general purpose serial line unit which can be used for a second terminal, a serial line printer, a TU58 DECtape II cartridge tape drive or other similar devices. The two switch packs (E135, E124) and jumpers W1, W4 and W9-W13 are used to configure the SLU1.

Switches S1-S8 of E135 are used select the various baud rates generated by the two baud rate generators contained on the CPU module. Table 2-2 lists the baud rates and their switch settings.

SLU1 transmit and receive baud rates are selected by S1-S4 of E124. Table 2-3 lists the switch settings and baud rate selected.

SLU2 transmit and receive baud rates are selected by jumper leads W4, W9-W13. Table 2-4 lists the baud rates and their respective jumper configuration.

Table 2-5 lists the jumper lead configuration for setting the number of stop bits on SLU1 and selecting and enabling parity in SLU1 and SLU2.

It is recommended to set SLU 1's transmit/receive baud rate to baud rate 1 and SLU 2's transmit/receive baud rate to baud rate 2. Thus baud rate 1 controls SLU 1 and baud rate controls SLU 2. Other baud rate configurations can be used; for a more detailed explanation of the baud rate logic and set-up refer to paragraph 4.7.3 of this manual.

2.8.2 M9312 Bootstrap/Terminator Module

The M9312 Bootstrap/Terminator Module is configured for use in the PDP-11/24 by 12 jumper leads (W1-W12). Five sockets on the M9312 are used to hold the ROMs which contain diagnostic routines and bootstrap programs used with the PDP-11/24 and its associated peripheral devices. Figure 2-24 shows the location of the jumpers and ROM sockets on the M9312 module. For a more detailed explanation of the M9312 refer to the M9312 Bootstrap/Terminator Module Technical Manual (EK-M9312-TM).

2.8.2.1 M9312 Jumper Configuration -- For use in the PDP-11/24, the jumpers on the M9312 module should be configured according to Table 2-6.

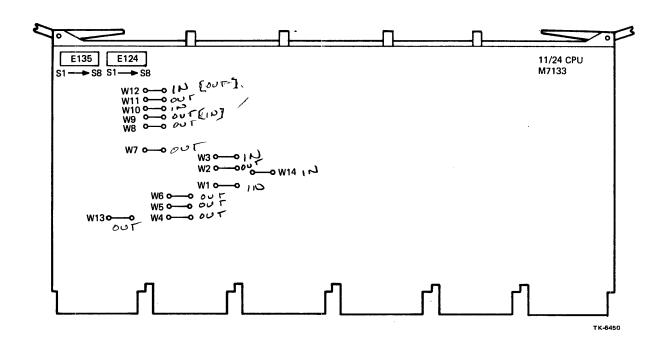

Figure 2-23 PDP-11/24 CPU Module, Jumper and Switch Locations

Table 2-1 CPU Module Jumper Lead Selection

	Jumper	Function
CPU:		
	W2	Controls power-up action
		<pre>IN = Boot on power-up OUT = Power-up via location 24g provided the</pre>
	W3	Controls Kernel Halt Enable
	:	IN = In kernel mode allows HALT instruction to be executed. In all other modes, a HALT instruction traps to location 10^8
		OUT = All halt instructions trap to location 10 ₈ (except during power-fail)
	W14	Selects boot address when boot on power-up is enabled.
		IN = 165000 OUT = 173000
SLU:		
	Wl	Determines number of stop bits in SLU1
		<pre>IN = One stop bit OUT = Two stop bits</pre>
		For manufacturing tests, the number of stop bits defaults to one.
	W4, W9-13	Select SLU2 Receiver and Transmitter baud rate
	W5-8	Determines parity of SLUs

W9-1Ø	IN	
W11-12	OUT	

2.8.2.2 M9312 ROMs -- The M9312 contains a CPU diagnostic ROM socket (E20), which accepts the PDP-11/24 CPU Diagnostic ROM, and four device boot ROM sockets (E32, E33, E34 and E35) which accept device bootstrap ROMs. The CPU diagnostic ROM checks the performance of the central processor and main memory when power is initially applied to the system or when a device bootstrap is initiated.

The device bootstrap ROMs contain device-dependent programs that will load programs from a selected peripheral device into main memory. The number and type of ROMs installed are dependent upon the devices in the system. A bootstrap program is initiated by the operator from the console terminal when selected by the BOOT position of the toggle switch on the front panel or via ODT. The processor executes the bootstrap program directly without the operator keying in the initial program.

Table 2-7 lists the location of the CPU diagnostic and bootstrap loader ROMs and the starting addresses associated with each. The selection of starting address determines whether the CPU diagnostic will be performed when the bootstrap program is initiated. The second devices listed in the table are for selecting a second device bootstrap program contained in the same ROM as the first device bootstrap program. Switches Sl through SlØ at location E37 of the M9312 module select the starting address of the bootstap program. Switch Sl determines the upper three digits of the starting address as follows:

S1 = ON (165XXX) (Boot to ODT [console mode])
S1 = OFF (173XXX) (Boot selected device)

Switch S2 on the M9312 module must be off for operation with the PDP-11/24.

Switches S3 through S10 are bits <08:01> of the starting address.

The position of the bootstrap ROMs on the module must be sequential, starting with BTl and progressing to BT4 as listed in Table 2-8.

For example:

To select an RL02 installed in the second ROM location (E33) and run the CPU diagnostic program, set the switches as follows.

 $RL\emptyset1/\emptyset2$ ROM in location E33 (Device ROM 1) Run diagnostics and then boot $RL\emptyset2$

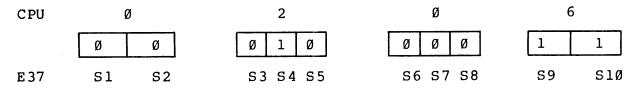

Table 2-7 CPU Diagnostic and Bootstrap Loader ROM Addresses

		S1<1>		S1 <3:	10>

Table 2-8 Bootstrap ROM Locations

Bootstrap ROM	IC Location
Device 1	E35
Device 2	E33
Device 3	E34
Device 4	E32

 $\emptyset = OFF$ 1 = ON

Table 2-9 lists the part numbers for available bootstrap ROMs. Some of the ROMs contain more than one device program. The DDCMP bootstrap loaders for the communication devices DL11, DMC-11, DU11 and DUP-11 are supplied in three ROMs for each device.

2.8.3 UNIBUS Map Module (M7134)

The UNIBUS Map module is an option available with the PDP-11/24 that gives the PDP-11/24 22-bit addressing capability through the use of a UNIBUS map. The module also contains an M9312 compatible bootstrap and a voltage monitor similar to that used in the PDP-11/44. The UNIBUS map module shown in Figure 2-25 contains 12 jumper lead locations and two switch packs located at E6 and E58.

2.8.3.1 UNIBUS Map Module Jumper Leads and Memory Page Selection — Table 2-10 lists the function of the jumper leads on the UNIBUS Map module.

Jumper leads TP1-TP10 and W3-W7 specify the lower and upper limit, respectively, of a set of UNIBUS addresses not mapped to main memory (asserted on the UNIBUS only). Except for the I/O page, every UNIBUS address not in this set is mapped to main memory (asserted on the memory bus) by the UNIBUS map. Devices on the UNIBUS should be addressed only in unmapped or I/O page address space.

When the upper and lower limits are set to the same octal bank (page) number, every non-I/O page address is mapped to main memory. Most Digital supplied configurations conform to this case. However, systems with UNIBUS memory or I/O devices that are located in the UNIBUS memory region require changes to be made to the mapping jumpers.

Table 2-11 lists the jumper leads selections for the lower limit of the set of unmapped addresses. UNIBUS addresses from zero to just below this limit are mapped to main memory. The octal bank number in this table is the first bank of the unmapped set, except when the lower and upper limits are set to the same bank number, in which case only the I/O page is unmapped.

Table 2-12 lists the jumper selections for the upper limit of the set of unmapped addresses. UNIBUS addresses above this limit and below 760~000 are mapped to main memory. The octal bank number in this table is the first mapped bank after the ummapped set, except when it is bank 37, the I/O page (always unmapped).

The following example describes the jumper selections for 3 pages (12K words) of UNIBUS device addresses immediately preceding the $\rm I/O$ page.

1. Page (bank) 37 is the I/O page; therefore, the three page to be unmapped are 34, 35, and 36.

- 2. Read jumper settings for TP10 through TP1 from the lower limit (Table 2-11) at bank 34, the first unmapped bank: TP1-TP2 = out, TP3-TP4 = out, TP5-TP6 = out, TP7-TP8 = in, and TP9-TP10 = in.
- 3. Read jumper settings for W7 through W3 from the upper limit (Table 2-12) at bank 37, the next bank after the unmapped set desired (34, 35, and 36): W3 = out, W4 = out, W5 = out, W6 = out, and W7 = out.

Notice that the upper limit "Decimal K Words" amount minus the lower limit "Decimal K Words" amount is equal to 12K Words. This is the size of the area desired.

2.8.3.2 Diagnostic and Bootstrap Loader ROMs -- The UNIBUS Map module contains a CPU diagnostic ROM and provides four sockets for the installation of device bootstrap ROMs. The CPU diagnostic ROM checks the performance of the central processor and main memory when power is initially applied to the system or when a device bootstrap program is initiated.

The device bootstrap ROMs contain device-dependent programs that will load device programs from a selected peripheral device into main memory. The number and type of ROMs that are installed are dependent upon the devices included in the system. A boostrap program is initiated by the operator from the console terminal when selected by the BOOT position of the toggle switch on the front panel or when requested via ODT. The processor executes the bootstrap program directly without the operator keying in the initial program.

Table 2-7 lists the location of the CPU diagnostic and bootstrap ROMs and the starting addresses associated with each. The selection of the first device starting address determines whether the CPU diagnostic will be performed when the bootstrap program is enabled. The second devices listed in the table are for selecting a second device bootstrap program contained in the same ROM as the first device bootstrap program. Switches Sl, and S3 through SlØ at location of E58 the UNIBUS map module select the starting address of the bootstrap program. Switch Sl determines the starting address of the upper three digits as follows:

```
S1 = ON (165 XXX) (boot to ODT [console mode])
S1 = OFF (173 XXX) (boot a device)
```

Switch S2 enables or disables the reading of the boot ROMs on the UNIBUS map module. The switch settings are as follows:

```
S2 = ON (Boot ROMs readable)
S2 = OFF (UNIBUS Map boot ROMs cannot be read)
```

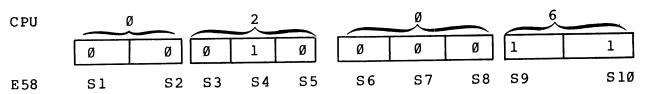

Switches S3 through S10 are bits <08:01> of the starting address.

The position of the bootstrap ROMs on the module must be sequential, starting with BTl and progressing to BT4 as listed on Table 2-13.

For example:

To select an RLO2 installed in the second ROM location (E89) and run the CPU diagnostic program set the switches as described in the following example.

RLØ1/Ø2 ROM in location E89 (Device ROM 2) Run diagnostics and then boot RLØ2

 $\emptyset = OFF$ 1 = ON

Table 2-9 lists the part numbers for the available bootstrap ROMs. Some of the ROMs contain more than one device progam. For example, the RP02/03, RP04/5/6, and RM02/3 bootstrap programs are contained in one ROM. Other devices may require more than one ROM. The DDCMP bootstrap loaders for the communication devices DL11, DMC-11, DU11 and DUP-11 are supplied in three ROMs for each device.

2.8.3.4 Voltage Monitor Switch Selection -- Table 2-14 lists the function of the switches associated with the voltage monitor circuit on the UNIBUS Map module. The normal switch configurations for the BAll-L and BAll-A mounting boxes are shown in Table 2-15.

2.9 INITIAL POWER-UP AND SYSTEM CHECKOUT This section describes the procedure to be followed for the initial power-up of and operator introduction to the 11/24.

2.9.1 Power Check

Verify that the outlet(s) into which you will plug the 11/24 is supplying the correct voltage that the computer system is configured for. If in doubt, consult field service or your electrician.

If the 11/24 is part of a packaged system, place each of the power controller circuit breakers in the "OFF" (\emptyset) position (See Figure 2-26). Insert each of the power cords into the appropriate outlets. The neon lamp(s) on each power controller should illuminate.

2.9.2 Power-Up

Ensure that the toggle switch on each power control is in the "REMOTE" position. Ensure that the CPU keyswitch is in the "DC OFF" position and that each of the individual unit switches and/or

Table 2-13 Bootstrap ROM Locations

Location	Bootstrap ROM
E75	Device 1
E89	Device 2
E82	Device 3
E83	Device 4

Table 2-14 Voltage Monitor Switch Selection

Switch (E6)	Function
S1	Selects +5B voltage monitor output for diagnostic purposes ON - Connected to monitor circuit OFF - Isolated from monitor circuit
S2	Selects -15A voltage monitor output for diagnostic purposes ON - Connected to monitor circuit OFF - Isolated from monitor circuit
S3	Selects the expected memory voltage ON $-\frac{+15B}{+12B}$ (BA11-L) OFF $-\frac{+}{+12B}$ (BA11-A)
S4	Selects <u>+</u> 15B or <u>+</u> 12B (determined by S3) voltage monitor output for diagnostic purposes ON - Connected to monitor circuit OFF - Isolated from monitor circuit

Table 2-15 Voltage Monitor Switch Settings

	Моц	inting Box
Switch	BAll-L	BA11-A
S1	ON	ON
S2	ON	ON
S3	ON	OFF
S4	ON	ON

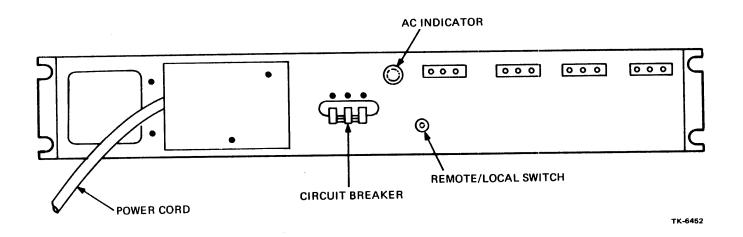

Figure 2-26 874-D,-E Power Controller

circuit breakers is "ON" on all equipment in the system. The circuit breaker in the BAll-L mounting box is made accessible by pulling the CPU out of the wrap-around approximately 5 inches. The circuit breaker on the BAll-A mounting box is located at the back of the unit. Place each of the power controller circuit breakers in the "ON" (1) position.

Place the CPU "HALT/CONT/BOOT" switch in the "HALT" position. Place the keyswitch in the "LOCAL" position. All units in the computer system should now power-up. If any units do not, verify that the power contol bus is properly routed from the CPU to each power control in turn. Verify also that each power control is in the "REMOTE" position and that its circuit breaker is ON (1). Verify that all unit switches and/or circuit breakers are on.

If the CPU has powered-up successfully, the front-panel "DC ON" LED should be illuminated and the "RUN" light should have flashed. The CPU has now halted so the console terminal should now be displaying the ODT prompt:

nnnnnn @

where nnnnn is an octal number representing the updated program counter.

At this point, the user has complete control of the 11/24 via Console ODT. The following procedure is recommended, both to verify operation of the 11/24 and to familiarize yourself with its operation.

The 11/24 contains diagnostics in the form of a ROM. These diagnostics are run whenever the system is bootstrapped. They may be invoked in either of two ways:

- 1. Momentarily place the "HALT/CONT/BOOT" switch in the "BOOT" position, then return it to "CONT".
- 2. Type 165000G at the console terminal.

Both of these actions cause the CPU to begin executing instructions starting at location 165000. These instructions verify correct operation of the CPU, the memory, and the Console Serial Line (SLUI). When complete, the terminal will print out the system memory size. This should conform to the expected memory size. Table 2-16 provides the translation from the octal memory size to bytes and words.

The 11/24 will now attempt to boot up the device selected by an internal switchpack. This is usually the main mass storage device on the system. Sections 2.8.2 and 2.8.3 of this chapter contain information on the set up of this switch pack. The setting of the switch pack may be over-ridden by starting at other addresses.

Table 2-16 Memory Diagnostic Size Indication

Printout	Memory Size	
0040000	128K Bytes	64K Words
01000000	256K	128K
0200000	512K	256K
0300000	768K	384K
0400000	1024K	512K

Refer to sections 2.8.2 and 2.8.3 for a description of this function.

At this point, you should load your diagnostic media (typically RX02 floppy disk or RL02 cartridge disk) into drive 0 and take the necessary action to bring the media on line. Write-protect the diagnostic media if possible. The selected device will be bootstrapped as soon as it is ready and XXDP+, the diagnostic monitor, should present its introductory message.

The console terminal (typically) contains the following dialogue (Text typed by the user is underlined):

165000

@165000G01000000

(The XXDP+ introductory message)

Diagnostics or chains of diagnostics may now be run. Specific information on the PDP-11/24 diagnostics is available in Chapter 9 of this manual. Information on XXDP+ is available in the XXDP+ User's Guide (AC-F348D-MC).

3.1 CONSOLE OPERATION

PDP-11/24 system communication between the user and the system is provided by the operator's console (Figure 3-1) and the console terminal which emulates the functions found on the traditional "lights and switches" console. The PDP-11/24 operator's console has a minimum number of lights and switches which perform basic functions and provide system status information.

3.1.1 Operator's Console Switches
The operator's console contains two switches: POWER and
HALT/CONT/BOOT. The function of each switch and its effect on
system operation is explained below.

Power (4-position rotary keyswitch)

DC	OFF	DC	po we	er	is	remov	ed	fro	om	the	syst	em;	con	tents
		are	MUS ∍ off	m e	emor	y are	10	st	and	l sy	stem	coo	ling	fans

LOCAL Power is applied to the system; Enables all functions and normal operation.

LOC DSBL Power is present throughout the system however, the HALT/BOOT switch is disabled and the "Break" key on the terminal will not halt the CPU.

STDBY DC power to most of the computer is off but DC power is applied to MOS memory to avoid data loss.

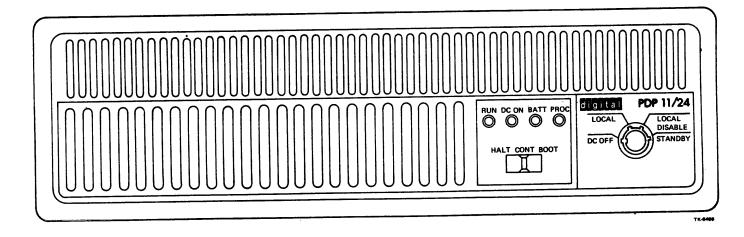

WARNING

The DC OFF position does not remove ac power from the system. AC power is removed only by disconnecting the line cord.

HALT/CONT/BOOT (3 position toggle switch)

HALT Halts the processor after all pending interrupts and aborts have been serviced.

CONT Continue; The processor is enabled for normal operation, however, it will not begin executing instructions until commanded to from the console.

BOOT Initializes the system; The processor will begin executing instructions contained in the hardware bootstrap.

When the boot switch is pressed or optionally on power-up (depending on a jumper setting in the CPU) the CPU begins executing instructions contained in the bootstrap ROMs. These instructions are diagnostics which test the CPU as well as other components in the system. On successful completion of the diagnostics, the instructions will bootstrap a device selected by the settings of the internal boot switches. If an error is detected by the diagnostics, the failing routine will cause a halt.

When the HALT/BOOT switch is in the HALT position, the system will boot up to ODT (Octal Debugging Technique). If the ODT prompt character (@) is not received on the console terminal move the switch to the BOOT position, then to the HALT position, then back to the CONT position. The switch should not, ordinarily, be left in the HALT position.

3.1.2 Operator's Console Indicators The four LEDs (RUN, DC ON, BATT and PROC) on the operator's console provide status information about the system. This information is described below.

RUN	ON	Processor is fetching instructions.
÷	OFF	Processor has halted or is waiting for an interrupt.
DC ON	ON	Indicates that dc power is available but does not imply that the power is within the required levels, unless the UNIBUS Map option is installed.
	FLASHING	The voltage monitor on the optional UNIBUS Map module has detected a voltage out of tolerance.
	OFF	Main +5 V is absent.
ВАТТ	OFF	Battery voltage is below the minimum level required to maintain the contents of MOS memory, battery backup is switched off, or the battery backup unit is not present in the system.

SLOW FLASH

Battery is charging and the voltage is above the minimum level required to maintain contents of MOS memory if power is removed. The amount of time that memory will be retained will depend on the amount of charge on the battery. The flash rate is fixed and does not vary with the charge rate of the battery.

FAST FLASH

Indicates that primary power has been lost and the battery is discharging while maintaining MOS memory contents. The flash rate is fixed and does not indicate the charge level remaining on the battery.

CONTINUOUS ON

Battery is present and fully charged.

PROC ON

Processor is the current UNIBUS master.

OFF

Processor is not the current UNIBUS master.

3.2 Console Terminal

The console terminal provides the communication link between the user and the processor. Although the PDP-11/24 does not have a traditional "lights and switches" console, ODT provides an equivalent function. It allows the processor to respond to commands and information entered via an ASCII terminal. Communication between the user and the processor takes place via ASCII characters interpreted as console commands. The console terminal addresses lie between 777560, and 777566. These addresses are generated in microcode and cannot be changed. The hardware associated with the console terminal is described in Section 4.6.

3.2.1 ODT OPERATION

The processor's microcode operates the serial line interface in half-duplex mode. Program I/O techniques are used rather than interrupts. When the ODT microcode is printing characters using the output side of the interface, the microcode is not monitoring the input side for incoming characters. Any characters coming in at this time may be lost. The UART chip may indicate overrun errors, but the microcode does not check any error bits in the interface, Therefore, users should not type ahead to ODT because those characters will not be recognized. In addition, if another processor is at the other end of the interface, it must obey half-duplex operation. No input characters should be sent until ODT has finished outputting.

Upon entry to ODT the RBUF register will be read using a DATI and the character present in the buffer will be ignored. This is done so that erroneous characters or user program characters are not interpreted by ODT as a command.

The input sequence for ODT is as follows.

- Test RCSR bit 7 (Done Flag) using DATI and if a zero, continue testing.
- 2. If RCSR bit 7 is a 1, read low byte of RBUF using a DATI.
 The output sequence of ODT is:
 - 1. Test XCSR bit 7 (Done Flag) using a DATI and if a zero, continue testing.
 - 2. If XCSR bit 7 is a 1, write XBUF using a DATO. The character is in the low byte and data in the high byte is undefined (The high byte is ignored by the Serial Line Unit).

If the interrupt enable (bit 6) in XCSR is set, an interrupt will be created to the software when the ODT command "P" is used. A "G" command will initialize the I/O system, clearing all the interrupt enables in peripherals and thus not cause an interrupt.

3.2.2 ODT ENTRY CONDITIONS ODT mode may be entered as follows.

- Execution of a HALT instruction in kernel mode, provided the ENABLE KERNEL HALT jumper is installed.
- Placing the HALT/BOOT switch in the HALT position and the key switch in the LOCAL position.
- 3. Pressing the "Break" key on the console terminal and the key switch in the LOCAL position.

Upon entry, ODT causes the following initialization:

- 1) Perform a DATI from RBUF (input data buffer at 777562) and then ignore the character present in the buffer. This operation is done so that erroneous characters or user program characters are not interpreted by ODT as a command.
- 2) Print a <CR> and <LF>
- 3) Print the contents of the PC (program counter) in 6 digits.

- 4) Print a <CR> and <LF>
- 5) Print the prompt character, "@"
- 6) Enter a wait loop for terminal input. The DONE flag (bit 7) in RCSR at 17777560 is constantly being tested via a DATI by the processor for a "1". If it's a "0", the processor keeps testing.

3.3 ODT COMMAND SET

The ODT command set is described in the following paragraphs. The commands are a subset of ODT-11 and use the same command character. Table 3-1 provides a list of the command set. ODT has 10 internal states. For each state only specific characters are recognized as valid inputs, other inputs invoke a response of "?". This is done to protect the user from accidentally destroying data via a syntax error. These states are described at the end of this section for reference.

The parity bit (bit 7) on all input characters is ignored (i.e., not stripped) by ODT and if the input character is echoed, the state of the parity bit is copied to the output buffer (XBUF). Output characters internally generated (e.g., <CR>) by ODT have the parity bit equal to zero. All commands are echoed except for <LF>.

In order to describe the use of a command, other commands will be mentioned before they have been defined. For the novice user, this section should be scanned first for familiarization and then re-read for detail. The word "location", as used in this section, refers to a bus address, processor register, or processor status word (PS). Bus addresses must be supplied as 18-bit addresses (i.e., the PSW, if accessed by its address, must be accessed via location 777776 and not 177776). The user's entry will be shown underlined while the response from the processor will not be underlined.

/(ASCII Ø57_o) Slash

This command is used to open an address, processor register, or processor status word and is normally preceded by other characters which specify a location. In response to /, ODT will print the contents of the location (i.e., six characters) and then a space (ASCII 40). After printing is complete, ODT will wait for either new data for that location or a valid close command. The space character is issued so that the location's contents and possible new contents entered by the user are legible on the terminal.

Example: @001000/012525 <SPACE> where:

@ = ODT prompt character

001000 = octal location in the bus address space desired

by the user (leading zeros are not required).

/ = command to open and print contents of location

012525 = contents of octal location 1000

<SPACE> = space character generated by ODT

Table 3-1 Console Command Language

Symbol	Octal Value	Definition
(slash)	Ø57	Opens a bus address, processor register, or processor status word.
CR (Carriage Return)	Ø15	Closes an open location.
LF (Line Feed)	Ø12	Closes an open location and opens the next contigious location (Bus addresses incremented by two, processor registers incremented by one).
\$	Ø 4 4	
or R (Internal Register) Designator)	122	Followed by a register number or "S", opens that specific processor register ("S" represents the processor status word).
G (Go)	107	Starts program execution at the location entered immediately before G. Causes a bus initialization.
P (Proceed)	120	Resumes execution of a program without initializing the bus.
Control-S (Binary Dump)	Ø23	Displays a portion of memory more efficiently than "/" or <lf> commands (not a normal user command).</lf>

The / command can be used without a location specifier to verify the data just entered into a previously opened location. will be recognized only if it entered immediately after a prompt character. A / issued immediately after the processor enters ODT mode will cause a ?<CR>, <LF>, to be printed because a location has not been opened.

Example: @1000/012525 <SPACE> 1234 <CR><CF> @/ØØ1234 <SPACE>

where:

first line = new data of 1234 entered into location 1000 and location closed with <CR>

= a / was entered without a location second line specifier. The previous location was reopened to reveal that the new contents

were correctly entered into memory.

CR (ASCII $\emptyset15_8$) Carriage Return This command is used to close an open location. If a location's contents are to be changed, the user should precede the <CR> with the new data. If no change is desired, <CR> will close the location without altering its contents.

Example: @R2/ØØ4321 <SPACE> <CR> <CR> <LF>

Processor register R2 was opened and no change was desired so the user issued <CR>. In response to the <CR>, ODT echoed <CR> and printed <CR>, <LF> and @.

@ R2/004321 <SPACE> 1234 <CR> <CR> <LF> Example: **a**

In this case, the user desired to change R2, the new data, 1234, was entered before issuing the <CR>. ODT deposited the new data in the open location and closed the location. ODT echoes the <CR> entered by the user and then prints <CR>, <LF>,0.

LF (ASCII 0128) Line Feed This command is used to close an open location and then open the next contiguous location. Bus addresses and processor registers will be incremented by two and one, respectively. If the PS is open when a <LF> is issued, it will be closed and a <CR>, <LF>, @ will be printed; no new location will be opened. If the open location's contents are to be changed, the new data should precede the <LF>. If no data is entered, the location is closed without being altered.

Example: $0 R2/123456 \langle SPACE \rangle \langle LF \rangle \langle CR \rangle \langle LF \rangle$ R3/Ø54321 <SPACE>

In this case, the user entered $\langle LF \rangle$ with no data preceding it. In response, ODT closed R2 and then opened R3. When a user has the last register, R7, open, and issues $\langle LF \rangle$, ODT will "roll over" to the beginning register, R0. When the user has the last address of a 32KW segment open and issues $\langle LF \rangle$, ODT will open the first location of that same segment. If the user wishes to cross the 32KW boundary, he must re-enter the address for the desired 32KW segment. (i.e. -- ODT is modulo 32KW). This operation is the same as that found on other PDP-11 consoles.

Example: 0R7/000000 <SPACE> <LF> <CR> <LF> of register R0/123456 <SPACE> 'rollover'

Example: 0577776/000001 <SPACE> <LF> <CR> <LF> of memory 400000/125252 <SPACE>
'rollover'

Unlike other commands, ODT will not echo the <LF> (ASCII 012). Instead it will print <CR>, then <LF> so that teletype printers operate properly. In order to make this easier for ODT to decode, ODT will also not echo ASCII 000, 002, or 010, It responds to these 3 characters with ? <CR>, <LF>, 0

\$ (ASCII 044g) or R (ASCII 122g) Internal Register Designator Either character when followed by a register number, 0 to 7, or the PSW designator, S, will open that specific processor register.

The \$ character is recognized to be compatible with ODT-11. The R character was introduced for the convenience of one key stroke and being representative of what it does.

Example: @ $\frac{\$\emptyset}{\emptyset}$ 000123 <SPACE> $\frac{\langle CR \rangle}{\langle LF \rangle}$ Example: @ $\frac{R\emptyset}{R1}$ 000123 <SPACE> $\frac{\langle LF \rangle}{\langle LF \rangle}$

If more than one character (digit or S) is after the "R" or "\$", ODT will use the last character as the register designator. An exception: If the last register designator equals $\emptyset 77$, ODT will open the PSW rather than R7.

Stack Pointer

R6, the stack pointer, deserves special attention. Two stack pointers actually exist; one for the kernel mode and one for the user mode. The selection of which stack pointer is to be used is based on the current mode bits of the PSW (bits <15:14>).

Example: @ $\overline{RS}/$ 140000 <SP><CR><LF>; The machine is in the user mode

- @ R6/ 123456 <SP><CR><LF>; The user stack pointer is examined
- @ RS/ 140000 <SP>0<CR><LF>; The machine is forced into the kernel mode

- @ R6/ 001000 <SP><CR><LF>; The kernel stack pointer is examined
- @ RS/ 000000 <SP>140000<CR><LF>; The machine is returned to the user mode

S (ASCII 123 $_{8}$) Processor Status Word This designator is for opening the PSW (processor status word) and can only be used after the user has entered an "R" or "\$" register designator.

Example: $\frac{0 \text{RS}}{100377} \text{ <SPACE>} \frac{\emptyset \text{ <CR>}}{0 \text{ <CR>}} \text{ <CR>} \text{ <LF>}$

Note the trace bit (bit 4) of the PS can't be modified by the user. This is done so that PDP-11 program debug utilities (e.g., ODT-11) which use the T bit for single stepping will not be accidentally harmed by the user.

If the user issues a $\langle LF \rangle$ while the PS is open, the PS will be closed and ODT will print $\langle CR \rangle$, $\langle LF \rangle$ @. No new location is opened in this case.

G (ASCII 107_8) Go This command is used to start program execution at a location entered immediately before the "G". This function is equivalent to the "LOAD ADDRESS" and "START" switch sequence on other PDP-11 consoles.

Example: @ 200G <NULL> <NULL>

The ODT sequence for a "G" is:

- l. Print two nulls (ASCII $\emptyset\emptyset\emptyset_8$) so that the bus initialize which follows will not flush the "G" character from the double buffered UART chip in the serial line interface.
- 2. Load R7 (PC) with the entered data. If no data is entered, \emptyset is used. (In the above example, R7 will equal $\emptyset\emptyset\emptyset2\emptyset\emptyset$ and that is where program execution will begin).
- 3. The PSW, (and Floating Point Status register if the MMU is present), will be cleared to \emptyset .
- 4. The bus will be initialized. Logic on the CPU module asserts BUS INIT for approximately 100 msec.
- 5. The processor will enter the service state. If there are any service conditions present, they will be processed.

If the BUS HALT L signal is asserted, the processor will re-enter the ODT state. This feature can be practically used to initialize a system without starting a program (R7 is altered). To single step a program issue a "G" and then successive "P" commands, all done with the halt switch in the "HALT" position.

P (ASCII 120_8) Proceed This command is used to resume execution of a program corresponds to the "CONTINUE" switch on other PDP-11 consoles. programmer visible machine state is altered using this command.

Example: @ P

Program execution resumes at the place pointed to by R7. the "P" is echoed, the ODT state is left and the processor immediately enters the state to fetch the next microinstruction. If the HALT signal is asserted, it will be recognized at the end of the instruction (during the SERVICE state) and the processor will enter the ODT state. Upon entry, the contents of the PC (R7) will be printed. In this fashion, a user can single instruction step through a program and get a PC "trace" displayed on the terminal. It should be noted that if a RESET instruction is executed during the time that "P" is being transmitted the echo of the "P" may be lost or corrupted.

H (ASCII 110_8) Toggle Halt Command The CPU may be single stepped by a second method: Instead of placing the HALT/BOOT switch in the HALT position the user can type an "H" at the console terminal. This action has the effect of toggling the Halt flip-flop located in the CPU. This action is the same as that done by setting the HALT/BOOT switch to the HALT position.

The CPU may now be single stepped by using the "G" and commands, previously discussed. When exiting the single step mode type "H" and the Halt flip-flop will be cleared.

To prevent accidental toggling of the Halt flip-flop the "H" that is typed must be uppercase (shift-"H"). All other ODT commands may be either upper or lower case.

NOTE

No indication is made as to the state of the HALT flip-flop. If the CPU doesn't seem to run the HALT flip-flop may be set or the HALT/BOOT switch may be in the HALT position.

Control-S (ASCII $\emptyset 23_8$) Binary Dump This command is used for manufacturing test purposes and is not a normal user command. It is described here to explain the

machine's response if accidentally invoked. It is intended to more efficiently display a portion of memory compared to using the "/" and <LF> commands. The protocol is as follows:

- After a prompt character, ODT receives a Control-S command and echoes it.
- The computer at the other end of the serial line must send two 8-bit bytes which ODT interprets as a starting address. These two bytes are not echoed.

The first byte specifies starting address <15:8> and the second byte specifies starting address <7:0>. Bus address bits <17:16> are always forced to be zero; the dump command is restricted to the first 32K words of address space.

3. After the second address byte has been received, ODT will output to the serial line, 10 bytes starting at the address specified previously. When the output is finished, ODT will print <CR>, <LF>, @.

If a user accidentally enters this command, it is recommended, in order to exit from the command, that two "@" characters (ASCII 100) be entered as a starting address. After the binary dump, the user will get a prompt character "@".

- 3.3.1 Address Specification All I/O addresses (124K to 128K) must be entered as 18-bit addresses, regardless of whether the MMU is present or not. For example, if it is desired to open the RCSR of the SLU1, enter "777 560_8 ", not 177 560_8 . Similarly, 18-bit addresses must be used to access memory greater than 32KW. Addresses $760~000_8-777~776_8$ will
- access memory greater than 32KW. Addresses 760 000 8-777 776, will map to the I/O page; memory at physical addresses 00 760 000 8-16 777 776, cannot be modified or examined via ODT.

3.3.2 Processor I/O Addresses - Certain processor and MMU registers have I/O addresses assigned to them for programming purposes. If address 777 7768 is referenced via ODT, the PSW will respond. Processor registers RØ thru R7 will not respond (i.e., time out will occur) to bus addresses 777 700_8 thru $777 700_8$ whether using ODT or a program.

The MMU contains status registers and PAR/PDR pairs. These registers can be accessed from ODT by entering their bus address.

Example: @ <u>777572</u>/000001 <SPACE>

In this case, memory mamagement status register \emptyset was opened and the memory management enable is seen to be set.

The FPll accumulators, which are also in the MMU chip, cannot be accessed from ODT. Only FPll instructions can access these registers.

3.3.3 Entering of Octal Digits

In general, when specifying an address or data, ODT will use the last six octal digits if more than six have been entered. Leading zeros do not need to be entered for either address or data; ODT forces zeros as the default.

3.3.4 ODT Timeout

When a nonexistent address is specified, ODT will respond to the bus timeout by printing ?, <CR>, <LF>, @.

3.3.5 Memory Parity Errors

If the trap enable bit has been set in the memory parity CSR that controls the bank of memory being examined, ODT will respond to a location containing bad parity by typing ?<CR><LF>@. The actual contents of the memory location may be read by specifically clearing the appropriate trap enable bit or by initializing the 11/24 processor. The memory word may then be read with no indication of its bad parity.

3.3.6 Invalid Characters

Any character which ODT does not recognize during a particular sequence will be echoed (with the exception of ASCII \emptyset , 2, 1 \emptyset , or 12 as noted earlier) and ODT will print a ?, $\langle \text{CR} \rangle$, $\langle \text{LF} \rangle$, \emptyset . ODT has 1 \emptyset internal states. When in a state only specific characters are recognized. In this way, an attempt has been made to lower the probability of a user unconsciously destroying himself by pressing the wrong key. Table 3-2 defines the states and valid input characters.

- 3.3.7 Correcting Type-In Errors
 ODT does not recognize the <RUBOUT> or <DELETE> character; if at
 any time the user realizes that a number has been incorrectly
 typed the error may be corrected by typing the six correct digits.
 ODT recognizes only the last six digits typed. For example:
 - @ <u>0010 772430/</u> 000000 <SPACE> ; the user began to open location 001000 to open memory management PAR 0 instead.

Table 3-2 ODT States and Valid Input Characters

State	Example of Terminal Output	Valid Input	Comment
1	@	Ø-7 R, \$ G P CTL-S	Slash legal only if a location was previously opened.
2	@R OR @\$	Ø-7 S	The user has indicated that a register will be selected.
3	@ <u>Ri</u> OR @ <u>\$i</u>	Ø - 7	A register has been selected.
4	@ <u>R1/</u> 123456	Ø-7 CR LF	The selected register has been opened.
5	@ <u>RI/</u> 123456 <u>1000</u>	0-7 CR LF	New data has been supplied as the register's contents.
6	@ <u>1000</u>	Ø-7 / G	The user has indicated that a bus address is being selected.
7	@ <u>1000/</u> 123456	Ø-7 CR LF	The selected address has been opened.

3.4 PDP-11/24 Registers

CPU and I/O device registers contained in the PDP-11/24 are located in the upper 4KW (I/O Page) of the physical address space. Table 3-3 lists some of these registers and their addresses.

3.4.1 Processor Status Word

The processor status word (PSW) contains information on the current status of the PDP-11/24. This information includes: the current processor priority, current and previous operational modes, the condition codes describing the results of the last instruction, an indicator for detecting the execution of an instruction to be trapped during program debugging (Trap bit), and a bit indicating the temporary suspension of a CIS instruction. Figure 3-2 shows the format of the PSW and Table 3-4 describes the functions of each bit.

3.4.2 Serial Line Unit 1 Registers Serial Line Unit 1 (SLU1) is used by the console terminal of the PDP-11/24. The following paragraphs describe the functions of the various registers associated with SLU1.

- 3.4.2.1 SLU1 Receiver Control/Status Register (RCSR) -- Figure 3-3 shows the format of the SLU1 receiver control/status register (RCSR) and Table 3-5 lists and describes the functions of the bits.
- 3.4.2.2 SLU1 Receiver Data Buffer (RBUF) -- Figure 3-4 shows the format of the SLU1 receiver data buffer register and Table 3-6 lists and describes the functions of the bits.
- 3.4.2.3 SLU1 Transmitter Control/Status Register (XCSR) -- Figure 3-5 shows the format of the SLU1 transmitter control and status register (XCSR) and Table 3-7 lists the functions of the bits.
- 3.4.2.4 SLU1 Transmitter Buffer Register (XBUF) -- Figure 3-6 shows the format of the transmitter buffer register (XBUF) and Table 3-8 lists the functions of the bits.
- 3.4.3 Serial Line Unit 2 Registers
 Serial Line Unit 2 (SLU2) is a general purpose serial line unit which may be used for a second terminal, a serial lineprinter, a TU58 DECtape II cartridge tape drive, or other similar devices. The following paragraphs describe the functions of the various registers associated with SLU2.
- 3.4.3.1 SLU2 Receiver Control/Status Register (RCSR) -- Figure 3-7 shows the format of the SLU2 receiver control/status register (RCSR) and Table 3-9 lists the functions of the bits.
- 3.4.3.2 SLU2 Receiver Buffer Register (RBUF) -- Figure 3-8 shows the format of the SLU2 receiver buffer register (RBUF) and Table 3-10 lists the functions of the bits.

Table 3-6 SLU1 RBUF Bit Descriptions

Bit	Description
15	SLU1 Error - A read-only bit that is set to 1 when the SLU1 OR ERROR (bit 14), the SLU1 FR ERROR (bit 13), or the SLU1 PAR ERROR (bit 12) is set to 1. Cleared when the specific error bit(s) is cleared.
14	SLUl Overrun Error - A read-only bit that is set to l if the character in the RBUF has not been read before another character is received. Cleared by an initialize operation or when the RBUF is emptied.
13	SLU1 Framing Error - A read-only bit that is set to 1 when the character read does not include a valid stop bit(s). Cleared when a valid character is received. This bit may indicate an error in transmission or the reception of a "break" character.
12	SLUl Parity Error - A read-only bit that is set to 1 when the parity of the data in the RBUF is incorrect relative to the parity mode selected. This indicates an error in transmission. Cleared when the parity of the next character is validated.
11:08	Not used.
07:00	SLUl Receiver Data - Read-only bits that are the data character that was read from the terminal.

Table 3-10 SLU2 RBUF Bit Descriptions

Bit	Description
15	SLU2 Error - A read-only bit that is set to 1 when the SLU2 OR ERROR (bit 14) FR ERROR (bit 13), or the SLU2 PAR ERROR (bit 12) is set to 1. Cleared when the specific error bit(s) is cleared.
14	SLU2 Overrun Error - A read-only bit that is set to l if the character in the RBUF has not been read before another character is received. Cleared by an initialize operation or when the RBUF is emptied.
13	SLU2 Framing Error - A read-only bit that is set to 1 when the character read in the RBUF does not have a valid stop bit. Cleared when a valid character is received. This bit may indicate an error in transmission or the reception of a "break" character.
12	SLU2 Parity Error - A read-only bit that is set to 1 when the parity of the character read in the RBUF is incorrect relative to the parity mode selected. Cleared when the parity of the next character is validated.
11:08	Not used.
07:00	SLU2 Received Data - These are read-only bits that form the data character received.

- 3.4.3.3 SLU2 Transmitter Control/Status Register (XCSR) -- Figure 3-9 shows the format of the SLU2 transmitter control/status register (XCSR) and Table 3-11 lists the functions of the bits.
- 3.4.3.4 TU58 Transmitter Data Buffer Register (XBUF) -- Figure $3-1\emptyset$ shows the format of the SLU2 transmitter buffer register (XBUF) and Table 3-12 lists the functions of the bits.
- 3.4.4 Line Time Clock Control/Status Register (LTC) Figure 3-11 shows the format of the Line Time Clock control status register (LTC) and Table 3-13 lists the functions of the bits.
- 3.4.5 Memory Management Registers
 The 16-bit virtual address is translated to a 22-bit physical address by the memory management function. Four status registers, 16 page address registers (PARs), and 16 page descriptor registers (PDRs) are associated with memory management.
- 3.4.5.1 Status Register Ø (SRØ) -- Memory management status register Ø (SRØ) contains error flags, the page number whose reference caused the abort, and various status flags. The format of SRØ is shown in Figure 3-12 and bit descriptions are listed in Table 3-14.
- 3.4.5.2 Status Register 1 (SR1) -- This register is not used by the PDP-11/24. If an attempt to read this register is made, the register is read as 000000. This register cannot be written into. This register is included to avoid system bus errors if SR1 is referenced.
- 3.4.5.3 Status Register 2 (SR2) -- SR2 is loaded with the 16-bit PC received from the data chip. This occurs on all address cycles when the control information indicates that the current address on the bus is that of an instruction. The contents of SR2 are frozen when an abort flag is set. SR2 is a Read Only Status register. Figure 3-13 shows the format of SR2.
- 3.4.5.4 Status Register 3 (SR3) -- The 11/24 only uses two bits of this register, bits 5 and 4. When cleared, bit <05> disables the optional UNIBUS mapping logic and when set, enables the UNIBUS map. When cleared, bit <04> selects 18-bit mapping mode within the MMU and when set, selects 22-bit mapping mode in the MMU. This bit is used internally by the MMU. All other bits in the register are read as 0s. Figure 3-14 shows the format of SR3.
- 3.4.6 Display Register

 The display register is a write-only register located at address 17 777 570. Any attempt to read from this register will result in a trap through the vector at location 4. This means that instructions which perform a DATIP/DATO sequence (INC, DEC, and CLR) may not be used to access the display register. When accessing the display register a MOV instruction is the preferred instruction. This type of access is in keeping with the operation of the PDP-11/70. This register uses only bits 1 and 0 (Figure

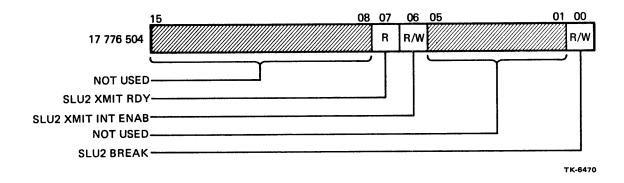

Figure 3-9 SLU2 XCSR Format

Table 3-11 SLU2 XCSR Bit Descriptions

Bit	Description				
15:08	Not used.				
Ø7	SLU2 Transmitter Ready - A read-only bit that is set to 1 when the SLU2 XBUF is ready to accept a character or when an initialize operation occurs. Setting the bit initiates an interrupt sequence if the SLU2 XMIT ENAB (bit $\emptyset 6$) is set to 1. Cleared when a character is written into the XBUF.				
Ø6	SLU2 Transmitter Interrupt Enable - A read/write bit that is set to 1 by the program to enable the interrupt sequence if the SLU2 XMIT RDY (bit 07) is set to 1. Cleared by the program or by the initialize sequence.				
Ø5:Ø1	Not used.				
ØØ	SLU2 Send Break - A read/write bit that is set to 1 by the program and that causes the serial output to be forced to the "spacing" condition. If this condition is held long enough it will be recognized as a break. Cleared by the program or by an initialize sequence.				

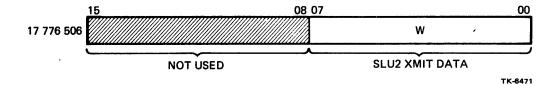

Figure 3-10 SLU2 XBUF Format

Bit	Description				
15:Ø8	Not used.				
Ø7	Line Time Clock Monitor - A read-only bit set to l for each cycle of the ac voltable and cleared by the program. Provides timing information at an interval of 16.66 ms on a 60 Hz power-line and 20 ms on a 50 Hz power-line. Also set during the initialize sequence. Cleared automatically after an LTC interrupt.				
Ø6	Line Time Clock Interrupt Enable - A read-write bit set to 1 by the program to allow the interrupt sequence to be initiated when the LTC MON (bit 07) is set.				
Ø5:00	Not used.				

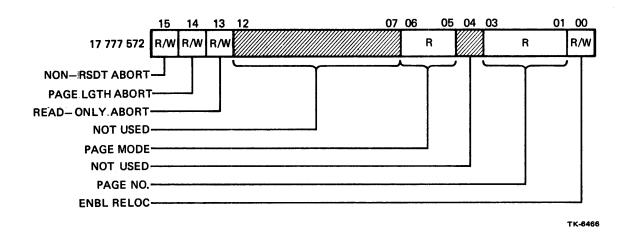

Figure 3-12 Memory Management $SR\emptyset$ Format

Table 3-14 SRØ Bit Descriptions

Bit	Description			
15:13	Error Flags - These error bits are prioritized; i.e., flags to the right are less significant and are to be ignored if a flag to the left is present. For example, a non-resident fault service routine would ignore page length and access control faults.			
15	Nonresident Abort - This bit is set to 1 when an attempt to access a page with an access control field (ACF) key is equal to \emptyset . It is also set if there is an attempt to use memory relocation with a processor mode of 2 or 1.			
14	Page Length Abort - This bit is set to 1 if there is an attempt to access a location in a page with a block number (virtual address bits 12:06) that is outside the area authorized by the page length field (PLF) of the page descriptor register (PDR) for that page. It is also set if there is an attempt to use memory relocation with a processor mode of 2 or 1. Bits 15 and 14 can be set simultaneously by the same access attempt.			
13	Read-Only Abort - This bit is set if there is an attempt to write in a read-only page. Read-only pages have an access key of 1.			
12:07	Not used.			
Ø6: Ø5	Page Mode - These bits indicate the processor mode (kernel/user) associated with the page causing the abort; kernel = $\emptyset\emptyset$, illegal mode = \emptyset 1, illegal mode = $1\emptyset$, user = 1 1. If an illegal mode is specified, bits 15 and 14 will be set.			
Ø 4	Not used.			
03:01	Page Number - These bits contain the page number of the reference causing a memory management fault.			
ØØ 	Enable Relocation - When this bit is set, all addresses are relocated. When this bit is clear, the memory management facility is inoperative and addresses are not relocated or protected.

ON	OFF	The processor test has successfully completed. Memory and memory management are now being tested.		
OFF	ON	The memory test has successfully completed and memory has been cleared to \emptyset s. SLUl is now being tested.		
OFF	OFF	All tests successfully completed. The console terminal will now print the memory size.		

4.1 INTRODUCTION

This chapter provides a functional description of the PDP-11/24 Central Processor and associated logic contained on the KDF11-UA (M7133) module. Simplified block diagrams are used to illustrate various sections of the logic. The print set will be referenced throughout the discussion.

4.1.1 Central Processor

The central processor in the PDP-11/24 is contained on two silicon chips. These two chips, the Data Chip and the Control Chip, contain the data paths, micro store, and micro sequencer. The two chips are mounted on a multilayer ceramic 40 pin hybrid. This 40 pin hybrid, called the DAT/CTL Hybrid, is then plugged into the PDP-11/24 CPU module (M7133).

All the basic PDP-11 processor functions are contained on this 40 pin hybrid assembly. The Data Chip Contains the PDP-11 register set, ALU, shifter, literal generation, conditional micro branching logic, and other functions associated with the data paths of a PDP-11 processor. The control chip contains the microprogram and the necessary microsequencing logic.

The DAT/CTL Hybrid contains the necessary microcode and logic to execute:

- 1. The basic PDP-11 instruction set
- 2. The Extended Instruction Set (EIS)
- The ODT console emulation

The DAT/CTL Hybrid along with its associated timing and interface logic makes up the "base machine" of the PDP-11/24 (Figure 4-1).

4.1.2 Processor Options

The PDP-11/24 base machine may be expanded by the addition of options which extend the microcode, the data paths or a combination of both.

4.1.2.1 Memory Management Unit -- The Memory Management Unit (MMU) is an extension of the data paths contained in the base machine (Figure 4-2). The MMU allows regions of memory to be relocated and/or protected. The MMU is contained on one silicon chip mounted in a conventional 40 pin IC.

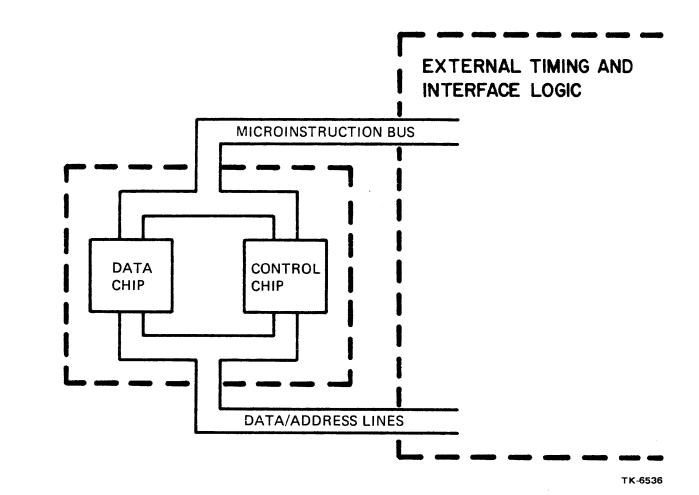

The MMU is installed in every PDP-11/24 and is considered optional because it is not needed for the base machine to function.

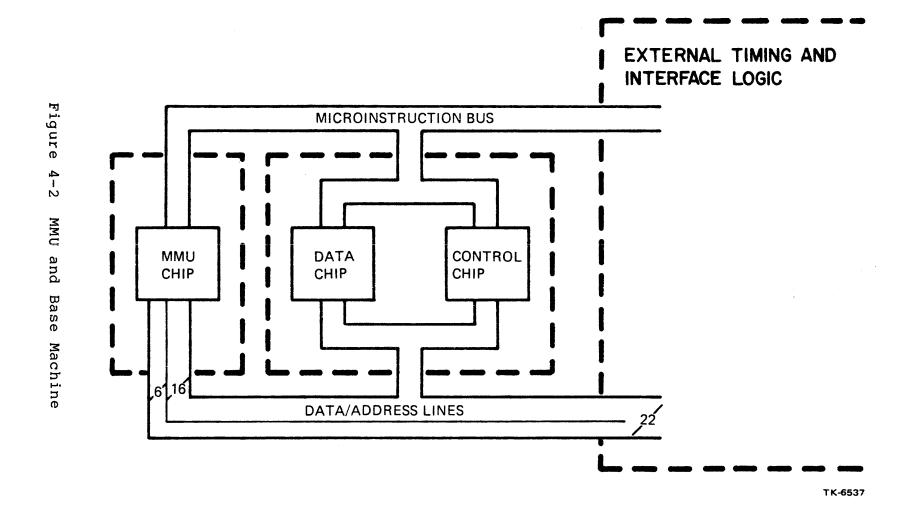

The MMU contains the registers, adders, and comparitors needed to generate a 22-bit physical address (PA) from the base machine's 16-bit virtual address (VA). The 22-bit address is transferred on the 16-bit wide DATA/ADDRESS Lines (DAL) plus 6-bit wide extension of the DAL (Figure 4-2).

Figure

Base

Machine

For a detailed explanation of how the MMU functions refer to Chapter 5, Memory Management, of this manual.

In addition to the memory management function of the MMU. The MMU contains the additional registers required by the Floating Point Processor.

Floating Point -- The Floating Point Processor (FPP) is 4.1.2.2 an extension of the data paths and microcode of the basic PDP-11/24 processor (Figure 4-3). The FPP requires additional registers which are contained in the MMU. The additional microcode and microsequencing logic required by the FPP is contained on two control chips mounted on a 40 pin ceramic hybrid FPP instructions are executed by the FPP microcode using the DATA chip and additional storage registers contained in the MMU. In normal operation the function of the Data Chip is controlled by the microinstructions contained in the Control Chip of the DAT/CTL Hybrid in the base machine. The base machine control chip will assert its CHIP SELECT line (CSEL 1 H) to indicate that it is selected and in control of the machine. When a floating point instruction is decoded the base machine control chip will issue a jump microinstruction to FPP control chip 1 and release the CHIP FPP control chip 1 recognizes its address in the SELECT line. jump microinstruction and becomes active. It indicates this by asserting its CHIP SELECT line. Processing of the floating point instruction now continues under the control of the first floating point control chip. If necessary, control will be passed to the second FPP control chip. When the instruction is complete, control is passed back to the base machine control chip. Only one control chip is in use at any time.

When the FPP is not installed or is not functioning properly the address in the jump microinstruction will not be recognized and the CHIP SELECT line will not be asserted. When the CHIP SELECT line is not asserted the external timing logic recognizes this as an error condition and will force a Chip Reset. The action forces the base machine control chip to take control of the machine. The base machine will then examine the service register and, noting that a CTL ERROR existed, force a trap through the vector at 10_8 . This trap notifies the user's program that a FPP instruction can not be executed.

4.1.2.3 Commercial Instruction Set -- The Commercial Instruction Set (CIS) is a microcode-only extension of the PDP-11/24's functions (Figure 4-4). CIS does not require the presence of the Memory Management chip. The CIS provides decimal arithmetic and byte-manipulation instructions. Six additional control chips contain the additional microcode used in the execution of the CIS. The CIS control chips are mounted on a double width 40 pin ceramic hybrid. Control is passed between the CIS control chips in the same way as it is in the FPP.

4.2 TIMING

The PDP-11/24 timing provides the enabling lines for various control signals to the chip set as well as other logic on the module. These timing signals are also used to indicate what type of information will be present on the Microinstruction Bus (MIB) or the Data/Address Lines (DAL). The PDP-11/24 has the following timing cycles: short cycle, address cycle, address relocation cycle, Data In cycle and a Data Out cycle.

Kl OSC H (75 ns) clocks a counter which generates Kl MCLK H. Kl MCLK H (300 ns) is divided into two time states, Phase Time (PTl through PT4) and Phase Bar Time (PBTl through PBT4). Phase Time is asserted when Kl MCLK H is high and Phase Bar Time is asserted when Kl MCLK H is low. Table 4-l describes the various time states and Figure 4-5 illustrates the timing flow for PDP-l1/24 operations.

4.2.1 Timing Cycles The various timing cycles used in the PDP-11/24 are explained in the following paragraphs.

4.2.1.1 Short Cycle -- The basic timing cycle used in the PDP-11/24 is the short cycle. A short cycle is 300 ns long and consists of PT1, PT2, PBT1 and PBT2. A short cycle is executed when there is no need to stop the base machine (i.e., no external I/O, no error conditions, etc.). Figure 4-6 illustrates a short cycle. The execution of microinstructions is pipelined, therefore two short cycles are illustrated.

The execution of a short cycle starts during PBT of the previous cycle when the microinstruction is read from the control store and is asserted on the Microinstruction Bus (MIB). The microinstruction is then latched into the Microinstruction Register (MIR) on the transition from the previous cycle's PBT to the current cycle's PT. When the microinstruction is latched, it is then replaced on the MIB by control information generated by the microinstruction. The control information is then used to control the internal and external logic in the processing of the data on the DATA/ADDRESS LINES (DAL). At the end of PT2 the data on the DAL is latched into the DATA chip. During PBT1 and PBT2 the DAL is supplied with service information and fetches the next The microcode can then use the information on microinstruction. the DAL to modify the microaddress used to fetch the next microinstruction.

4.2.1.2 Input/Output Cycles -- Timing cycles that have input or output (I/O) to the system bus require additional time to complete the transfer process. Two types of I/O cycles exist:

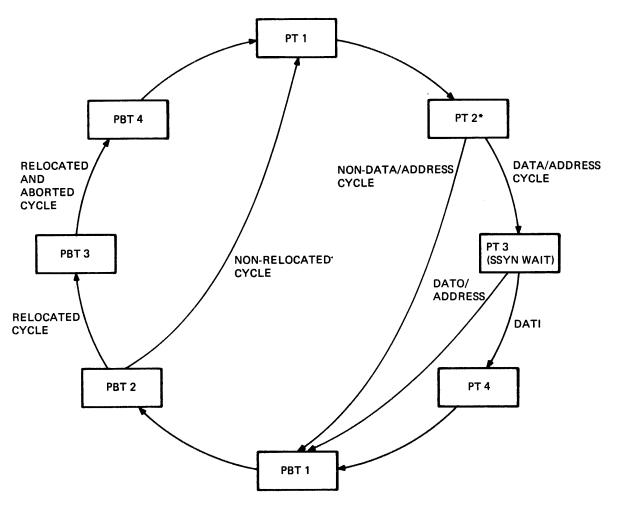

- 1. Address Cycle This cycle specifies the address and control information.
- Data Cycle This cycle performs the actual transfer of data.

Table 4-1 PDP-11/24 Timing States

Timing	State	Description
PT1 (Phase	Time 1)	Beginning of the microinstruction execution. PT2 immediately follows.
PT2 (Phase	Time 2)	Second state for microinstruction execution. If the microinstruction does not specify an address operation or external data operation this is the final execute microinstruction state. If this is an address microcycle, execution continues in PT3. If an external data operation is to be performed and the data cycle requires the UNIBUS or EUB, the processor will wait in PT2 until the UNIBUS or EUB is available. Execution will then continue in PT3.
PT3 (Phase	Time 3)	This state is used to wait for Slave-Sync or allow additional time for the assertion of a virtual address. It is entered only if an address microinstruction or data-type microinstruction is being executed. If the microinstruction is a DATI (Data-In) PT4 is asserted next. Any other microinstruction causes PBT1 to be asserted after PT3. This state will be stretched to wait for Slave-Sync from a device if this is a data-type microinstruction.
PT4 (Phase	Time 4)	This state is used to provide UNIBUS data deskew. It is at the end of this time state that data from the UNIBUS is latched into the processor.
PBT1 (Phase	Bar Time 1)	This is the beginning of a microinstruction fetch. Also, during this time state the MMU may be translating a virtual address into the appropriate physical address. PBT2 immediately follows.
PBT2 (Phase	Bar Time 2)	Second state for microinstruction fetch. If no address relocation is taking place PT1 immediately follows. If an address relocation cycle is enabled PBT3 immediately follows. A microjump to a non-existent control chip will result in PBT3 being entered.

Table 4-1 PDP-11/24 Timing States (Cont)

Timing	State	Description				
PBT3 (Phase	Bar Time 3)	The translated physical address from the MMU is available on the DAL. PBT4 immediately follows.				
PBT4 (Phase	Bar Time 4)	PBT4 is asserted during a relocation cycle to allow time for the translated physical address from the MMU to be read. PBT4 is also asserted when an abort or reset condition occurs. When an abort or reset condition occurs PBT4 provides the time needed to reestablish normal micromachine operation. PT1 immediately follows.				

*DURING A UNIBUS DATA CYCLE THE CPU WILL WAÏT, IF NECESSARY, FOR THE UNIBUS TO BECOME AVAILABLE.

Figure 4-5 PDP-11/24 Timing Flow

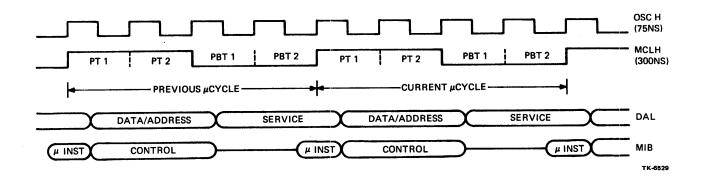

Figure 4-6 Pipelined Flow of Short Cycle

The address cycle will be described first and then the data cycle.

Address Cycles

The address cycle specifies the address and type of data cycle to be performed. These are two types of address cycles, non-relocated and relocated. The cycle to be used is determined by whether the Memory Management Unit (MMU) is enabled or disabled. When the MMU is enabled it takes the 16-bit virtual address (VA) and converts it to a 22-bit physical address (PA). This function uses a relocated address cycle. A non-relocated address cycle uses the 16-bit VA as the PA.

A non-relocated address cycle is similar to a short cycle, see Figure 4-7. The address generated by the DATA chip is used as the PA. The PA along with control signals CØ and Cl are strobed into the PAX latch at the end of PT3. CØ and Cl are used to determine the type of data transfer to be performed, see table 4-2. The remainder of the cyle is the same as a short cycle.

A relocated address cycle, Figure 4-8, requires additional time to allow for the generation of the relocated PA. The VA is strobed into the PAX Latch and latched into the MMU at the end of PT3. The MMU begins the address relocation at this time. Since the MMU requires the use of the DAL during address relocation the service information that is usually on the DAL during PBT is inhibited. Approximately 180 ns into PBT the relocated address is present on the DAL. The relocated PA is then strobed into the PAX latch at the end of PBT3. If the address relocation is successful (i.e., legal) the address cycle is complete. If there is an MMU error or illegal access error the MMU will assert K13 ABORT L (Figure 4-9) and force control back to the DAT/CTL hybrid. The base machine will then read the service register and, recognizing an MMU error, will cause the execution of a trap through the vector at 244g. This trap notifies the user's program of an MMU abort.

Data Cycles

Data cycles are used to transfer data from the processor to memory or a peripheral device. Data cycles normally follow address cycles. A data cycle is generated using a short cycle that is altered to meet the transfer requirements of the memory bus (EUB) or Unibus. The processor is synchronous and the EUB and Unibus are asynchronous, therefore it is necessary to stop the processor clock and wait for the EUB or Unibus to complete the data transfer. Figure 4-10 shows the timing for the various data cycles.

A data cycle begins with the latching of the microinstruction on the transition from the previous cycles PBT to the current cycle's PT. Data cycle execution begins in PTl which is immediately followed by PT2 as in a short cycle. The processor then arbitrates for use of the bus with PT2 being extended in 75 ns increments until the bus is free. PT3 is then entered and the

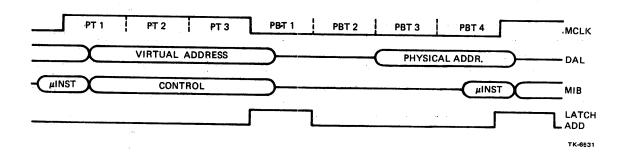

Figure 4-8 Relocated Address Cycle

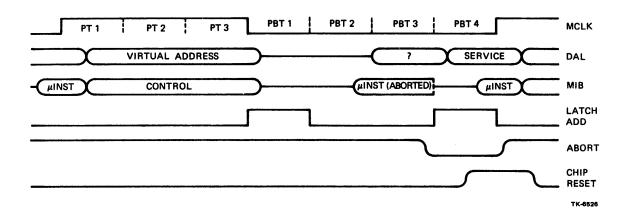

Figure 4-9 Relocated Address Cycle - Aborted

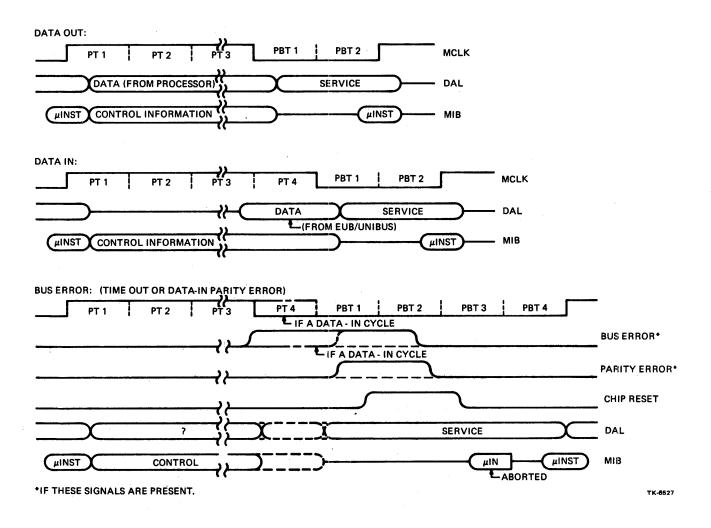

Figure 4-10 Data Cycles

processor clock is stopped until the data transfer is completed and BSSYN H is asserted. The processor clock is stopped during PT3 because BSSYN H may not be asserted during the 75 ns of PT3. If a data-out operation was being performed the data transfer is complete at the assertion of BSSYN H and PBT l is entered. If a data-in operation was being performed it is necessary to allow an additional 75 ns deskew time before latching the data into the processor, therefore PT4 is entered to allow for the deskew time. The data is latched into the processor on the transition of PT4 to PBT1. Other aspects of UNIBUS timing are discussed in paragraph 4.5.2.

If a bus timeout error or bus parity error occurred during the data transfer CHIP RESET will be asserted and PBT3 and PBT4 will be entered to force control back to the base machine control chip. The base machine control chip will execute the appropriate trap $(114_8 \text{ or } 4_8)$ to inform the user's program of the error.

4.2.2 Timing Logic

Phase Time and Phase Bar Time are generated by the logic illustrated in Figure 4-11. Most processor timing is controlled by a Programmed Logic Array (PLA) which monitors the control information on the MIB. The PLA does not directly generate the time states but controls the timing circuit shown in figure 4-12 via the signal CHG CLK L. CHG CLK L asserted during Phase Time (MCLK H) initiates Phase Bar Time, or when asserted during Phase Bar Time (MCLK L) initiates Phase Time. CHG CLK L will be asserted at various times according to the operation to be performed. The PLA timing equations in the print set specifies when CHG CLK is generated. The various inputs to the timing PLA and the corresponding outputs are illustrated in Figure 4-11.

When a short cycle microinstruction is executed (no address/data transfer to take place) PBTl must be asserted after PT2. In order to assert PBTl, CHG CLK L must be asserted. In this case the Timing PLA 'looks' only at the following inputs: MCLK H, CTl and MIB <12,8,9>. According to the Timing PLA equation CHG CLK L will be generated in this case, if MCLK H is asserted (indicating Phase Time), CTl H (from the time state counter) is asserted and MIB <12,8,9> are set indicating a non I/O operation. If these conditions are met CHG CLK L will be asserted clearing MCLK H and initiating Phase Bar Time.

When any of the other timing cycles is being executed the PLA will assert CHG CLK L at the required times. The Timing PLA also controls the I/O control signals (CØ, Cl, LAT ADD, etc.).

4.3 PDP-11/24 CENTRAL PROCESSOR

The PDP-11/24 Central Processor is composed of a data chip and a control chip mounted on one 40 pin hybrid package. A detailed description of each chip follows.

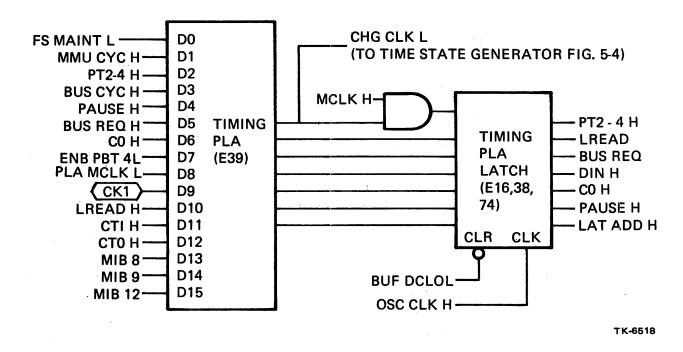

Figure 4-11 PLA Control Signals

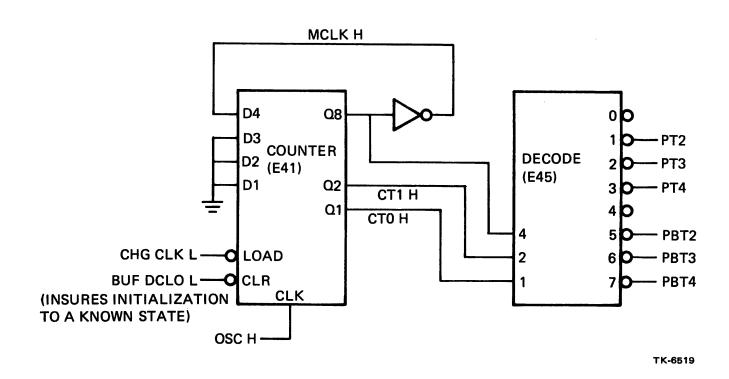

Figure 4-12 Phase Time and Phase Bar Time Generation

4.3.1 Control Path

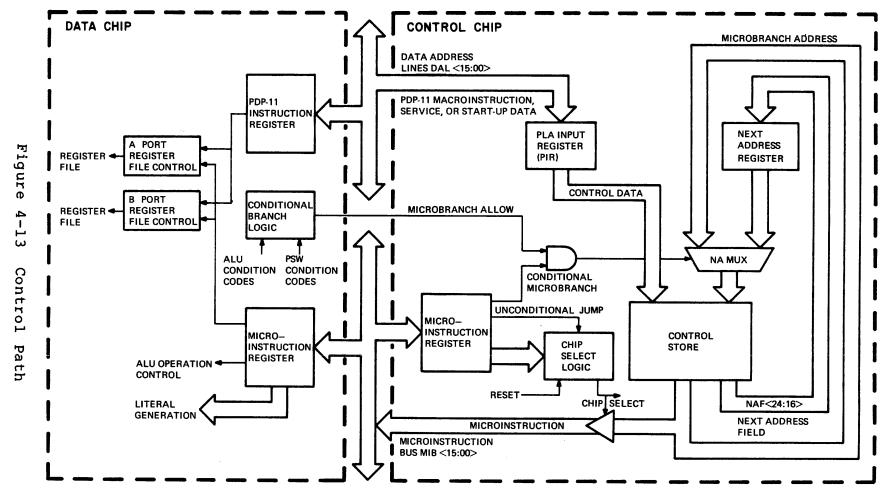

The control path allows for the transfer of microinstructions from the control chip to the other chips in the system via the MIB<15:00>. Figure 4-13 is a simplified block diagram of the control path. The control store is divided into four quadrants. Quadrant 1 is a PLA and quadrants 2, 3, and 4 are conventional ROM.

The PLA input register (PIR) stores external data or service information from the DAL which is used to access locations within the control store. The control store contains microinstructions which reside within the address range 000000_8 through 000777_8 . Each location contains a 25-bit word composed of a 16-bit microinstruction and the 9-bit next address field (NAF) needed for the next microinstruction fetch. The format of the microword is illustrated in Figure 4-14.

PDP-11 macroinstructions are loaded directly from the DAL into the These microinstructions are used by the control store to generate the corresponding microinstructions for various Initial power-up will assert CHIP RESET. operations. assertion of CHIP RESET will return control of the processor to the base machine control chip. The processor then enters the service state, microaddress Ø, and service information is read into the PIR. The service information consists of service request data. Service information is placed on the DAL<15:00> during Phase Bar Time (Figure 4-15) and comes from various sources within the PDP-11/24. The upper three bits (DAL<15:13>), however, are ignored by the processor base machine chip and replaced by service information internal to the control chip. Table 4-3 describes the DAL service information and Table 4-4 gives the priority level. As seen in Figure 4-16, ENB SVC L causes service information to be placed on the DAL. ENB SVC L is asserted every Phase Bar Time during PBT2 if ther is no MMU cycle (MMU CYC L cleared) in progress. During MMU cycles, service information is not asserted and is replaced by the relocated physical address from the MMU chip. In addition to Initial Power-Up the processor will be reset and forced to service as a result of any of the following: A control error (reserved instruction trap), an MMU error, a parity error, a bus error, or DLY DCLO H.

If the processor has entered the service state as a result of Initial Power-Up the microcode must properly initialize the total processor. The power-up action to be taken is determined by startup information read from logic external to the processor base machine.

System start-up information from the Fast Data-In register is placed on the DAL <15:00> during Phase Time. ENB FDIN L allows the start-up information to be placed on the DAL. This signal is generated after PTl (during PTl through PT4) if the GPO code on the MIB is 10, indicating system power-up. It is also generated during a Halt instruction to check if Kernel-Halt is allowed.

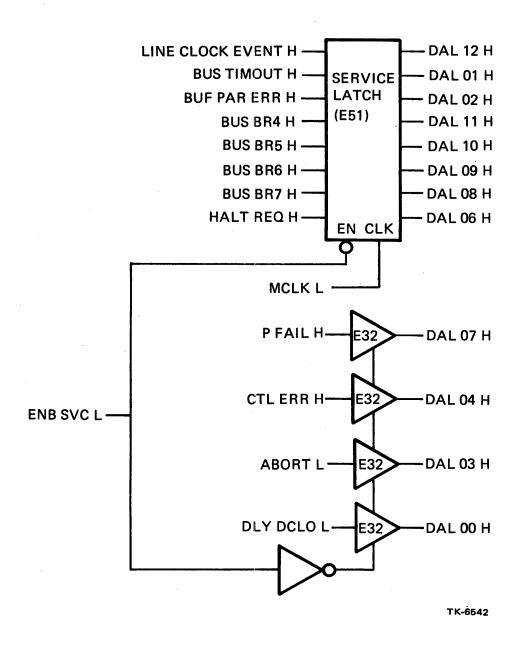

Figure 4-16 Service Information Logic

Figure 4-17 and Table 4-5 describe the information in the Fast Data-In register.

4.3.2 Microinstruction Bus (MIB<15:00>)

The Microinstruction Bus (MIB) contains the next microinstruction during Phase Bar Time and various control information during Phase Time. Figure 4-18 illustrates the bit assignments of the MIB during Phase Time and Phase Bar Time. Part of this control information consists of the AIO bits, X codes, and General Purpose Output (GPO) code bits which are encoded to specify particular functions. The remaining control bits each relate to an operation or status indication. A description of MIB control information is provided in Table 4-6.

The AIO codes are used by the Timing PLA shown in Figure 4-11 to generate the proper control signals. The Timing PLA equations in the print set show the necessary AIO codes for particular outputs from the PLA. The GPO codes are used by different portions of logic external to the chip set. The 'X' control bits are used internally by the chip set.

4.3.3 PDP-11/24 Data Path

A block diagram of the data path is provided in Figure 4-19. Data flow through the data path is controlled by the microcode. Each microinstruction from the control store generates a unique set of outputs on the MIB which control the data path elements and determine the ALU functions to be performed. Sequences of these microinstructions are combined into microroutines, which perform various PDP-11 instruction operations. The Arithmetic Logic Unit (ALU) performs the arithmetic, logical, and shifting operations in the data chip. The ALU has four status flags associated with its operation. These status flags are updated at the conclusion of an ALU operation, and are conditionally written under microprogram control into the PSW condition codes (in the data chip) at the end of a cycle. These ALU status flags are outlined below.

PDP-11/24	ALU CONDITION CODES
AN	ALU result is negative
AV	ALU operation resulted in an arithmetic overflow
AZ	ALU result is Ø
AC	A non-subtract ALU operation resulted in a carry
	(Subtract type operations caused a borrow)

The data path multiplexer selects one of three inputs for transfer to the byte swapper. These inputs are: the DAL<15:00>, the Internal A bus (A<15:00>), and the output of the ALU. Selection of these inputs depends on whether the PS address mode is active or not, and the input microinstruction. The byte swapper either passes the output of the multiplexer through unaltered or interchanges the bytes of the word. Byte swapping occurs with the execution of SWAB or when inputting or modifying a byte during an external bus cycle that references an odd address.

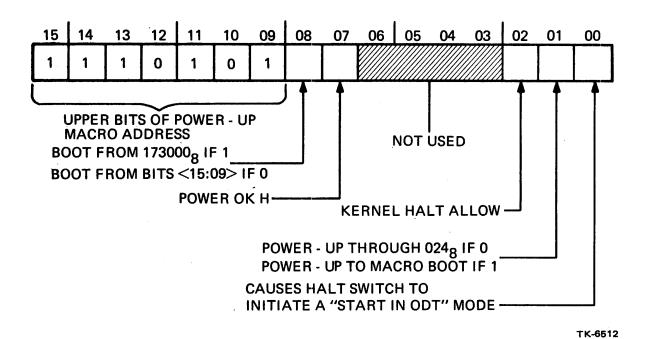

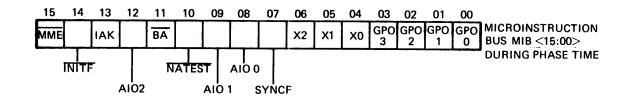

Figure 4-17 Fast Data-In Register

Figure 4-18 Microinstruction Bus

Table 4-6 Microinstruction Bus Control Information

MIB Bits	Description					
MIB<15> MME	Memory Management Enable This active-low signal indicates to the data chip that the virtual address from the data chip will be relocated during the second-half of the microinstruction cycle (PBT). The two sources of this signal are the MMU chip or logic external to the chip set which detects an ODT cycle and simulates the MMU.					
MIB<14> INIT F	Initialization This active-low signal triggers a 100 ms one-shot (print K2) which generates the UNIBUS initialization signal BUS INIT L.					
MIB<13> IAK	Interrupt Acknowledge This signal is asserted high during an input vector microinstruction. It is used to indicate to external logic that a vector-in bus operation is occurring.					
MIB<12,9,8> AIO<02:00>	Address In/Out These three encoded signal lines tell external logic whether or not a bus cycle is being performed and the type of cycle. The signals are encoded as follows:					
	AIO2 AIO1 AIOØ Operation					
	Ø Ø Ø AWO Address cycle (Write) Ø Ø l ARW Address cycle (Read/Modify/Write)					
	Ø 1 Ø Unused					
	Ø l l ARO Address cycle (Read)					
	1 Ø Ø DOUTB Data Out Byte					
	1 Ø 1 DOUT Data Out Word					
	$egin{array}{cccccccccccccccccccccccccccccccccccc$					
MIB<11>BA	Branch Allow L This asserted low signal is generated by the data chip to indicate to the control chips that the requested microbranch condition is true. This allows the conditional microbranch to occur.					
MIB<10> NATest	Next Address Field Test This asserted low signal is used during control chip testing. The control chip will output its Next Address Field rather than output the micro- instruction.

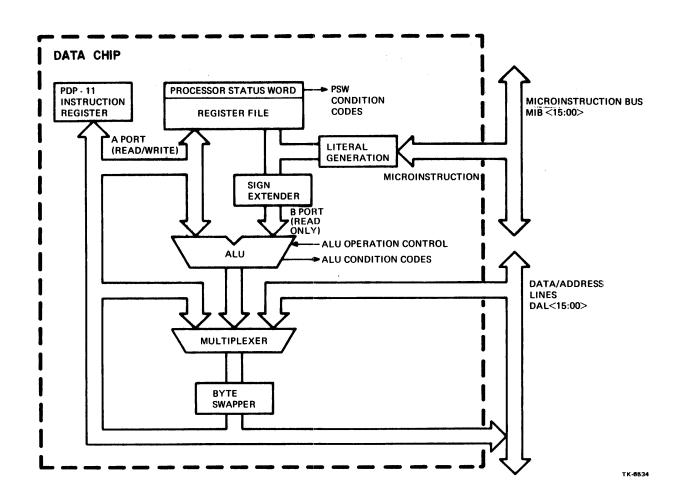

Figure 4-19 Data Path

4.3.4 Data Address Lines (DAL<15:00>)

The 16-bit DAL output transfers addresses and data from the data chip to the UNIBUS and the MMU chip as well as the BDAL and the control chip. Information is output onto the DAL for all output microinstruction cycles during Phase Time. Service information is placed on the DAL during Phase Bar Time. The 16-bit DAL input receives information from the UNIBUS, the MMU chip, or other sources during Phase Time. All data is connected to the register file via the data path multiplexer and byte swapper. PDP-11 instructions are loaded directly into the instruction register. The DAL also contains information for use in the PSW explicit address logic. Explicit references directly access the PSW. This information is saved and used during Phase Bar Time when the register file is written and updated. The DAL input to the data chip is active during phase bar time of relocation operations to load the new address from the MMU chip into the PSW explicit address logic.

- 4.4 PDP-11/24 CHIP SET CONTROL LOGIC
 The chip set control logic shown in Figure 4-20 generates two signals, CHIP RESET H which goes to each control chip in the chip set and CTL ERR H which is placed on DAL <04> at PBT2. CHIP RESET H is used to reset the chip set when any of the following conditions occur:
 - o ABORT L asserted indicating a relocation operation error in the MMU.
 - o BUS ERR H asserted indicating a UNIBUS error.
 - o BUF PAR ERR H asserted indicating a parity error on the UNIBUS.
 - o DLY DCLO H asserted indicating that an unacceptable power level is available to the system.
 - o CSEL 1 L or CSEL 2 L is not asserted indicating that no control chip acknowledged receipt of a jump microinstruction.

CHIP RESET H will be asserted at the end of PBT2 and will be cleared at the beginning of PT1. CHIP RESET H causes a service cycle to occur. If CHIP RESET H is asserted because no control chip asserted its chip select line, CTL ERR H will be asserted. CTL ERR H indicates that either the selected control chip is not present in the system or it did not assert its chip select line. During the service cycle the CTL ERR bit (bits <04>) of the service register will indicate the error. The service cycle will determine which condition caused the chip reset. BUF DCLO L clears CTL ERR H to insure proper system initialization.

4.5 SYSTEM BUS LOGIC
The two external busses used by the PDP-11/24 are the UNIBUS and the 22-bit Extended UNIBUS (EUB). The UNIBUS carries all external data transfers and UNIBUS addressing performed by the PDP-11/24. The EUB is used to address memory only, memory data is transfered on the UNIBUS data lines.

4.5.1 Address and Data

4.5.1.1 Address -- Addresses generated by the processor for use in I/O cycles are latched from the DAL into the PAX latch (K7). The PAX latch then drives the internal PAX bus (see Figure 4-21). Logic in the processor then determines the destination of the address that the processor has generated and routes it to the proper bus. There are three types of addresses:

- 1. Internal Address
- 2. Main Memory Address
- 3. UNIBUS Address

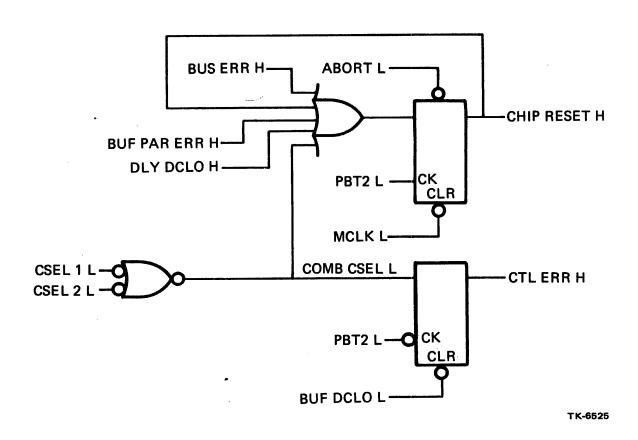

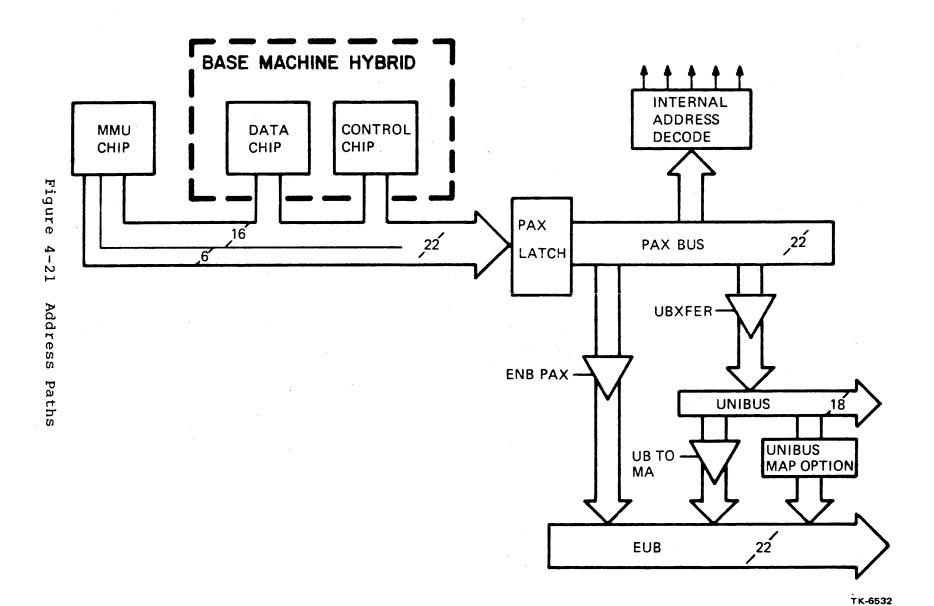

Figure 4-20 PDP-11/24 Chip Set Control Logic

Internal addresses, i.e., serial line unit registers, are decoded by a PLA and its associated logic (K9). There is no external bus cycle performed for an internal address.

Main memory addressing requires a 22-bit address be passed to main memory using the EUB (Kll). I/O page address are also passed to main memory so the memory parity control and status registers can be accessed. The signal Kll ENB PAX L enables the 22-bit address and control information onto the EUB.

UNIBUS addressing requires the 22-bit physical address to be truncated to 18-bits by dropping bits <21:18> of the physical address. The 18-bit address is passed to the Unibus (K11) when K7 UBXFER L is asserted. It should be noted that control bits CØ and C1 are also transmitted with the address.

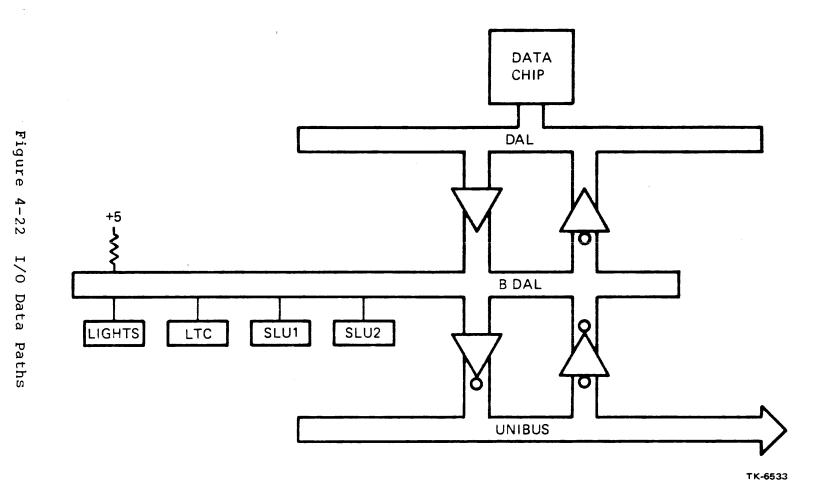

4.5.1.2 Data Paths -- Data is transferred to and from the processor via a set of busses different from that used by address information. Figure 4-22 shows the path used by the data. When performing a Data Out the data is passed from the DAT chip to the DAL and is then gated onto the BDAL (K4 and K5) by K4 DIR IN L not being asserted. If the data is to be used external to the processor (i.e., memory or UNIBUS) the data is gated onto the UNIBUS data lines by the assertion of K1 ENB DAT L.

NOTE

Main memory uses the UNIBUS data lines for data transfers. The EUB is used for address and control information only.

When performing a Data In the data transferred from main memory or a UNIBUS device is put on the UNIBUS data lines. The data is then gated from the UNIBUS to the BDAL by the assertion of K4 UBUS TO B DAL L. The data is then gated from the BDAL to the DAL and passed to the procesor by the assertion of K4 DIR IN L.

- 4.5.1.3 Direct Memory Access -- A Direct Memory Access (DMA) is when a UNIBUS device directly accesses main memory without CPU intervention. This action in the PDP-11/24 requires that the UNIBUS address be passed to the EUB. The PDP-11/24 accomplishes this in one of two ways:
 - 1. The UNIBUS address can be passed to the EUB using logic contained on the PDP-11/24 module (K10). This logic examines UNIBUS address bits <17:13> and ANDs them together. The output of the AND gate, K11 I/O PAGE H, is then passed to EUB <21:18>. This action forces UNIBUS I/O page address to go to the EUB I/O page. UNIBUS address bits <17:00> and control bits C0 and C1 are passed to the EUB unchanged.

2. The optional UNIBUS Map Module (M7134), if installed, is responsible for passing the UNIBUS address to the EUB. The UNIBUS Map may pass the address unchanged or relocate it as requested by the user's program. For a more detailed explanation as to how the UNIBUS Map option functions refer to Chapter 6 of this manual.

Address and control information can be passed from the UNIBUS to the EUB whenever the CPU is not using either of the busses. Because data going to and from main memory is transferred on the UNIBUS there is no need to alter it in any way.

When performing a DMA, the internal registers contained on the CPU (LTC, SLU1, SLU2, and the display register) can not be accessed. This is because ther is no way for either the UNIBUS or EUB to access the PAX bus thereby making the internal address decoder inaccessible to DMA activity.

4.5.2 System Bus Timing
When the CPU is performing a data transfer using the UNIBUS it becomes bus master and therefore must control the UNIBUS timing.

UNIBUS timing by the PDP-11/24 is generated by the logic on K1 and K2. When the CPU requires use of the UNIBUS or EUB (memory data is transfered on the UNIBUS data lines) the CPU asserts K1 PRE BUS REQ H. Logic on K2 (Figure 4-23) which monitors UNIBUS activity will assert K2 TAKE BUS H when the bus is free. K1 TAKE BUS H and K1 PRE BUS REQ H will cause the Bus Master flip-flop (E65) to be set on the next high to low transistion of the K1 OSC L. The Bus Master flip-flop (Figure 4-24) then asserts K1 PROC MAST H. The Bus Master flip-flop being set indicates that the processor is now the bus master.

UNIBUS timing requires that BBSY (Bus Busy) be asserted. This action tells all other devices on the UNIBUS that the bus is currently in use. BBSY is asserted by the processor when K1 PROC MAST H is asserted which asserts K1 ENB A+C H which asserts K2 BUS BBSY L. The assertion of K1 ENB A+C H also gates address and control information onto the UNIBUS. If this is a read cycle the processor waits for the requested data. If this is a write cycle K1 ENB DATA L is asserted and data is gated onto the UNIBUS.

The processor must now allow 150 ns for front end deskew; 75 nsec for differential skews in the UNIBUS and 75 ns for the UNIBUS devices to decode the address and control information. The 150 ns of front end deskew is created by delay line, E100. This is accomplished by the delay line not allowing K2 BUS MSYN L to be asserted for 150 ns after K1 PROC MAST H is asserted. Note that if a main memory transfer is taking place the EUB receives K1 MEM MSYN H only 120 ns after K1 PROC MAST H is asserted. This is possible because of the shorter length of the memory bus (a few inches) as compared to the length of the UNIBUS (a maximum of 50 feet).

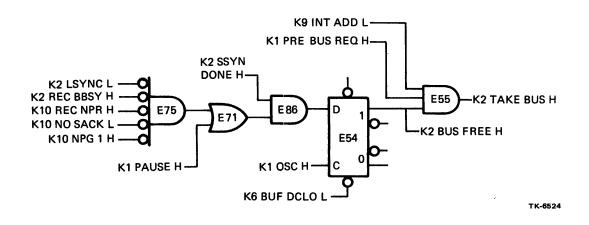

Figure 4-23 Bus Monitor Logic

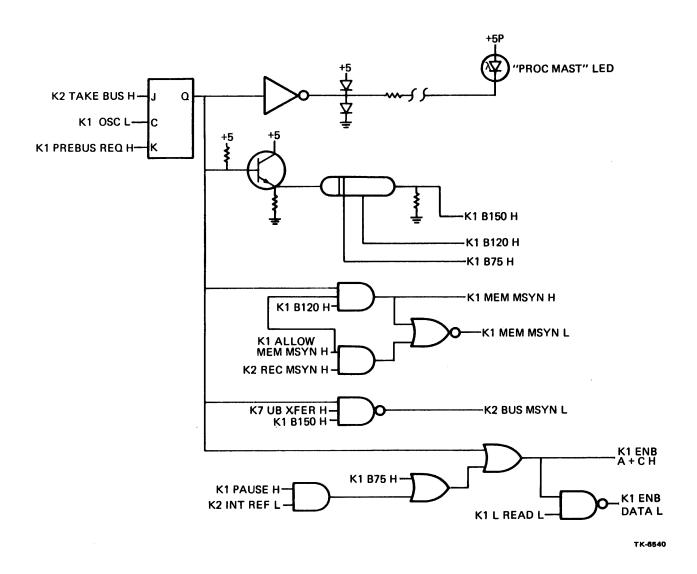

Figure 4-24 Unibus Timing Logic

During front end deskew the processor enters time state PT3, which stops the processor clock, and the processor waits for K2 BUS SSYN L to be asserted by the accessed device. The assertion of K2 BUS SSYN L along with K1 PROC MAST H being asserted will assert K2 BSSYN H which will restart the processor clock which will negate K1 PRE BUS REQ H. On the next high to low transition of K1 OSC L the Bus Master flip-flop (E65) will be cleared thus negating K1 PROC MAST H and K2 BUS MSYN L. UNIBUS timing requires that valid address and control information be maintained for 75 ns after the removal of MSYN. This is accomplished by delay line E100 delaying the negation of K1 ENB A + C H for 75 ns. This 75 ns time period is called tail end deskew.

When the processor is bus master the setting of the Bus Master flip-flop (E65) causes a LED, 'PROC', on the front panel to be illuminated. This allows the user to monitor the amount of the processor's bus activity.

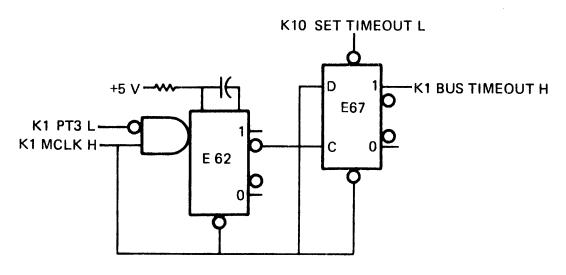

The following steps summarize system bus timing:

- Assert BBSY, address and control information, and if a write cycle, data.
- 2. Wait 150 ns Front End Deskew
- Assert MSYN
- 4. Wait for SSYN
- 5. Wait 75 ns (PT4) if a read cycle Data Deskew
- 6. Remove MSYN
- 7. Wait 75 ns Tail End Deskew
- Remove BBSY, address and control information, and data (if a write cycle)

4.5.3 System Bus Errors

Error conditions can occur during a UNIBUS cycle. One results from an attempt to address a non-existent or defective memory location or I/O device (Time Out). The second error is a result of reading from a memory location with bad parity (parity error).

4.5.3.1 Time Out Error -- When the processor initiates a Unibus or EUB cycle it asserts MSYN. After the processor has asserted MSYN the processor as bus master has to receive a SSYN signal, from the addressed device, within 25 us. Logic on K1 (Figure 4-25) is used to monitor the return of BSSYN. The processor waits for BSSYN during time state PT3. Entering time state PT3 stops the processor clock and holds K1 MCLK H asserted. This action triggers one shot E62. If BSSYN is not returned within 25 us, one shot E62 will time out and set flip flop E65 which asserts K1 BUS TIME OUT H signaling a bus time out error. When a time out error

TK-6541

Figure 4-25 Bus Timeout Logic

occurs the current operation is aborted and a trap through the vector at location 4 is executed. The one exception to this action is when the time out occurs while an interrupt vector is being read in which case no action is taken. If BSSYN is returned within 25 us, signaling a successful transfer, the processor clock is restarted and one shot E62 and flip flop E65 are cleared when MCLK goes low on the transition from PT to PBT.

4.5.3.2 Parity Error -- Modern memory systems employ methods of error detection and in some cases error correction. If an uncorrectable error is detected when reading from memory the memory subsystem notifies the processor by asserting K2 PB L and not asserting K2 PA L. This action causes K2 PAR ERR H to be asserted and the processor to abort the current operation. When the operation is aborted the processor will trap through the vector at location 1148. The exception to this is when the console is in the console ODT mode in which case an error is indicated by ODT printing ?<CR><LF>@.

4.6 INTERNAL ADDRESS DECODE

The internal address decode logic shown in Figure 4-26 provides I/O units contained on the processor module with the necessary control information. The Address Decode PLA monitors the address lines PAX<12:00>, control line C0, L READ, FS MAINT from the field service maintenance switch, and L BSIO which indicates a reference to the I/O page. The print set contains the PLA truth table for the internal address decode logic. The truth table specifies the necessary inputs to the Address Decode PLA to generate the control information for the SLUs, the Line Time Clock, and the internal display register (two LEDs located on the Module). Two decoders are used to generate the actual control signals for the I/O units. One decoder generates the control signals that enable the reading of registers, the other generates the control signals that enable the writing of the I/O registers. The read decoder is enabled when.

- The Address Decode PLA has the address of a valid internal register.
- DIR IN H asserted, indicating that the data transfer direction is inward as a result of an input microinstruction.
- Output of the SLU Timing shift register is low.

Table 4-7 describes the outputs of the read decoder.

The write decoder is enabled when:

^ The Address Decode PLA has decoded a data out to an address of a valid internal register.

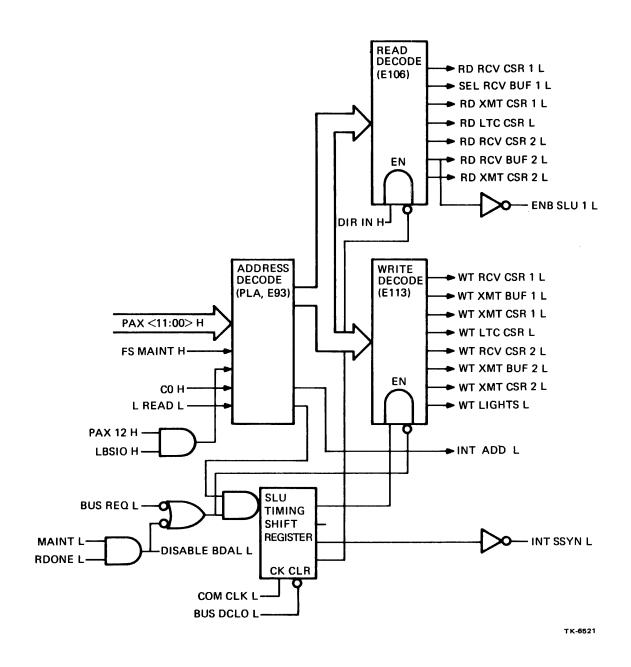

Figure 4-26 Internal Address Decode

Table 4-7 Read Decoder Outputs

Decoded Output	Description
RD RCV CSR 1 L	Reads the contents of the SLU1 Receiver Control/Status register of SLU1 onto the BDAL.
SEL RCV BUF 1 L	Reads the contents of the SLU1 receiver data buffer onto the BDAL.
RD XMT CSR 1 L	Reads the contents of the SLU1 Transmitter Control/Status register onto the BDAL.
RD LTC CSR L	Reads the contents of the Line Time Clock Control/Status register onto the BDAL.
RD RCV CSR 2 L	Reads the contents of the SLU2 Receiver Control/Status register onto the BDAL.
RD RCV BUF 2 L	Reads the contents of the SLU2 receiver data buffer onto the BDAL.
RD XMT CSR 2 L	Reads the contents of the SLU2 Transmitter Control/Status register onto the BDAL.

- BUS REQ L asserted indicating a data transfer or MAINT L, RDONE L asserted.
- Output of the SLU Timing shift register is low.

4.7 SERIAL LINE UNITS

4.7.1 Console Terminal SLU

The console terminal SLU (SLU1) is the I/O port for an LA36 or equivalent EIA serial console. The console terminal operates in two modes: as the system terminal (program I/O mode) or as the programmer's console terminal (console mode).

In the console mode the terminal is used to functionally replace the switch register and light display of the traditional control panel. In this mode all characters input on the terminal are interpreted as console commands. Chapter 3 provides a description of the console commands. In the program I/O mode the terminal provides the user with an information path to and from a running program. SLU1 enables the transfer of data between the processor (parallel data) and the external terminal (serial data). The Universal Asynchronous Receiver/Transmitter (UART) (Figure 4-27) is the major functional area of the interface. The UART operation is described in the following sections.

Transmitter Operation -- Parallel data to be transferred 4.7.1.1 from the central processor to the terminal is input to the UART on the BDAL (BDAL<0.7:0.0>). When the UART is in the idle state the serial output (SERIAL OUT 1 H) is high. The parallel data is strobed into the UART by WT XMIT BUF 1 H. When the data is transferred to the transmitter shift register in the UART, XMT RDY 1 H will be asserted indicating that the data is being transferred to the terminal, and new data may be loaded into the transmitter data buffer register. The format of the serial character is Three jumpers provide determined by control inputs to the UART. the necessary control signals for the format of serial data. description of these jumpers is provided in Table 4-9. The rate at which the serial data is transmitted is switch selectable and outlined in Section 4.7.3.

4.7.1.2 Receiver Operation

The receiver section of the UART accepts a serial character from the terminal for conversion to parallel data. The parallel data is transferred on the BDAL<07:00>. The receiver samples the serial line input (UART SI 1 H) at selected edges of the receiver clock (RCLK 1 H). The source of the data for the serial line input is a multiplexer. During normal operations, the multiplexer selects serial data from the terminal (SERIAL IN 1 H). In the maintenance mode the multiplexer selects the serial output of the UART (SERIAL OUT 1 H). This enables a closed loop test of the receiver and transmitter.

Table 4-8 Write Decoder Outputs

Decoded Output	Description
WT RCV CSR 1 L	Writes data from the BDAL to the SLU1 Receiver Control/Status Register.
WT XMT BUF 1 L	Writes data from the BDAL to the SLU1 Transmitter Data Buffer.
WT XMT CSR 1 L	Writes data from the BDAL to the SLU1 Transmitter Control/Status Register.
WT RCV CSR 2 L	Writes data from the BDAL to the SLU2 Receiver Control/Status Register.
WT XMT BUF 2 L	Writes data from the BDAL to the SLU2 Transmitter Data Buffer.
WT XMT CSR 2 L	Writes data from the BDAL to the SLU2 Transmitter Control/Status Register.
WT LIGHTS L	Writes data from the BDAL to the internal display register on the CPU Module.
WT LTC CSR L	Writes data from the BDAL to the Line Time Clock Control/Status Register.

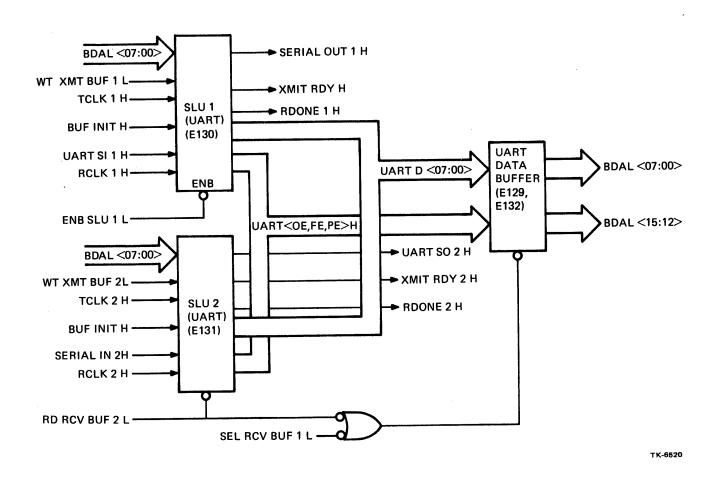

Figure 4-27 Serial Line Interface

Table 4-9 SLU1 Data Format Jumpers

Jumpers	Description
W5	When IN allows parity generation and checking, when OUT inhibits parity generation, checking and forces the Parity Error bit in the Receiver/Data Buffer Register to be cleared.
W6	When IN the UART generates and checks ODD parity, when OUT the UART generates and checks EVEN parity.
Wl	Stop bit Select When IN-1 stop bit is generated (above 110 baud) When OUT-2 stop bits are generated (110 baud and below)

The receiver becomes active when it detects a mark to space (high to low) transition of the serial line input. It then shifts in the required number of data bits, the parity bit (if enabled), and the stop bit(s). The contents of the shift register are then transferred into the receiver data holding register and the data available flag (R DONE) is set.

If the receiver parity detection has been enabled (Jumper W7 IN), the receiver checks the parity of the data bits plus the parity bit following the data bits. The receiver compares the parity of the received data with the parity select line. Even or odd parity check is determined by Jumper W9. If the parity of the received character differs from the parity of the UART control logic, the parity error line (UART PE H) is asserted. This causes bit 12 (Parity Error) as well as bit 15 (Error) of the receiver data buffer register to be set.

The receiver samples the first stop bit which occurs after the parity bit or after the data bits if no parity check is selected. If the stop bit(s) are valid (logical 1), it indicates that the entire character has been correctly received. A low on the first stop bit sampled by the receiver indicates an invalid stop code. The UART will then generate a framing error signal (UART FE H) which sets bit 13 (framing error) and bit 15 (error) in the terminal receiver data buffer register.

A Framing error can be caused by pressing the 'break' key on the console terminal. If the console key switch is in the LOCAL position, the Framing error will pass to the halt request line and stop the processor. This allows ODT mode to be entered without the user leaving the console terminal.

In addition to the parity error and framing error conditions, a third error condition (overrun) is associated with receiver operation. The overrun condition indicates that a new character has been loaded into the UART holding register before the previous character was removed. This destroys the character already there. The UART will assert the overrun error line (UART OE H) when this occurs. Bit 14 (overrun error) and bit 15 (error) of the receiver data buffer register will also be set.

4.7.1.3 SLU 1 Maintenance Configuration — The console terminal interface has two maintenance features which allows the UART as well as other portions of the interface to be checked. The maintenance bit (Bit Ø2) of the Transmitter Control/Status register allows the looping of the transmitter's serial output back into the serial input of the receiver (Figure 4-28). A diagnostic routine contained in the M9312 diagnostic ROM sets this bit. Upon successful completion of the diagnostic routine the maintenance bit will be cleared. Other diagnostics use this bit in a similar fashion.

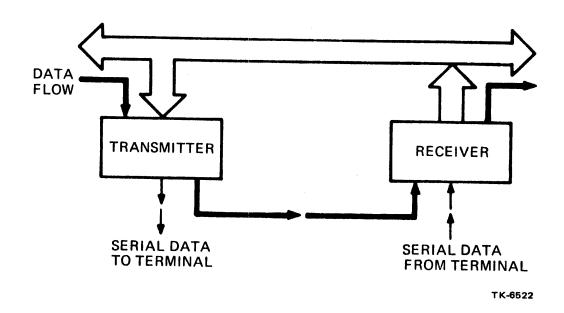

Figure 4-28 Maintenance Bit (XCSR) Maintenance Configuration

NOTE

The maintenance bit is set under program control. It should never be set from the console. This will effectively remove the console from the system, in which case a system initialization is necessary to allow the console terminal to be used again.

The maintenance switch on the module (S2-5) allows the looping of the received data back to the transmitter via the BDAL (Figure 4-29). The terminal is effectively put in local when the maintenance switch is set. This tests the receiver, transmitter, baud rates and part of the internal data bus. The operator sets the switch and then types a <U> or an <*>. The <U> should be received back as an <*> and the <*> should be received back as a <<U>. This will indicate proper operation of the terminal, UART and a portion of the BDAL. This function is performed entirely without CPU intervention, however, it will destroy the program's state. The SLU shift register (K9) times operation of SLU1 while in Field Service Maintenance mode.

- 4.7.2 Serial Line Unit 2
 Serial Line Unit 2 (SLU2) provides a general purpose I/O port for the user. Operation of SLU2 is similar to that of SLU1. Serial data transferred to and from the I/O port is converted to parallel data for use by the central processor. As in SLU1 the UART is the major functional area of the interface.
- 4.7.2.1 Transmitter Operation (SLU2) -- Parallel data on the BDAL (BDAL<07:00>) is loaded into the UART when the processor performs a DATO(B) to the SLU2 UART transmitter data buffer. The address decode logic generates WT XMT BUF 2 L which loads the data on the BDAL into the UART transmitter data buffer.

The parallel data is converted to serial data by the UART and transmitted via UART SO 2 H. The I/O device receives the UART data via SERIAL OUT 2 H. The format of the serial data is determined by control inputs to the SLU2 UART. These control inputs are jumper selectable and are described in Table 4-10.

The SLU2 transmitter functions are similar to those of SLU1. SLU2 has the additional capability of transmitting a "break" which will set a framing error at the user's receiver. This is done by setting bit Ø in the SLU2 XMITR CSR (K8). The serial output of SLU2 will be held spacing as long as bit Ø is set. Bit Ø must remain set until the time a stop bit would have been set. The easiest way to time this is by transmitting characters on SLU2. The characters will not be sent since the line is held spacing but the done bit is operational and properly timed. To overcome the double buffering of the UART at least two characters (NULLS) should be sent, then bit Ø may be cleared.

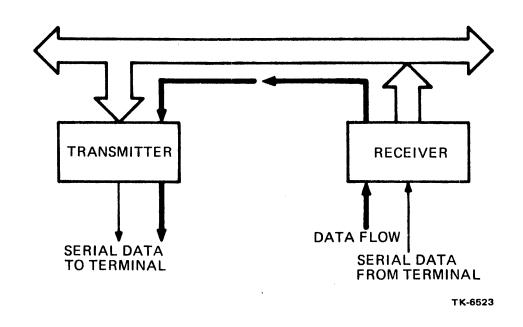

Figure 4-29 Maintenance Switch (S2-5) Maintenance Configuration

Table 4-10 SLU2 Data Format Jumpers

Jumpers	Description
W8	When IN the UART generates and checks ODD parity, when OUT the UART generates and checks EVEN parity
W7	When IN allows parity generation and checking, when OUT inhibits parity generation, checking and forces the Parity Error bit in the Receiver Data Buffer Register to be cleared.

4.7.2.2 SLU2 Receiver Operation -- The receiver accepts serial data from user's device. The SLU2 UART does not have the diagnostic feature which allows the serial output of the UART to be fed back into the serial input. In order to perform a diagnostic check, a loopback connector (H325 or equivalent) and the appropriate diagnostics are required. All other receiver operations are similar to SLU1.

4.7.3 Baud Rate Logic

The baud rates for the console terminal receiver and transmitter are derived from a 2.7648 MHz crystal oscillator. This crystal controlled clock is then fed to:

- 1. A dual rate baud generator which develops two independent rates (50 to 19200 baud).
- 2. A fixed divider which develops 19200 baud.

The dual baud rate generator has switch selectable inputs which select its two output frequencies and the corresponding baud rates. Table 2-2 lists the switch settings and resulting baud rates.

The two switch selectable outputs (E135 S1-4 and S5-8) from the dual baud rate generator are known as K8 BR1 H and K8 BR2 H. The fixed 19.2K baud rate signal is called K8 19.2K BAUD. These three signals are then fed through switch pack E124 S1 through S4 and jumpers W4, W9-W13 to determine the SLU baud rates.

The SLU1 transmitter baud rate is selected by S1 and S2 of E124. The receiver baud rate is selected by S3 and S4 of E124. This arrangement allows the transmitter and receiver to be set to the same baud rate (baud rate 1 or 2), or to be set to different baud rates. When setting the transmitter and receiver to different baud rates the transmitter can be set to baud rate 1 and the receiver set to baud rate 2 or the transmitter set to baud rate 2 and the receiver set to baud rate 1. Table 2-3 lists the switch settings for SLU1 baud rates.

The SLU2 transmitter and receiver baud rates are selected by jumpers W4, W9-W13. The baud rates may be selected in a manner similar to SLU1 with the addition of the fixed 19.2K baud rate.

4.8 LINE TIME CLOCK (LTC)

The Line Time Clock (Figure 4-30) provides the system with timing information at fixed intervals of 16.7 msec (60 Hz line frequency) or 20 msec (50 Hz line frequency). The LTC is KWll-L compatible with the exception of the monitor bit which is automatically cleared after each interrupt. While in the interrupt mode an interrupt is generated for each cycle of the line frequency. When the interrupt mode is disabled the monitor bit may be tested and cleared under program control without causing an interrupt. The Line Clock Status Register (LKS) contains two bits associated with the LTC operation: a monitor bit to provide noninterrupt mode

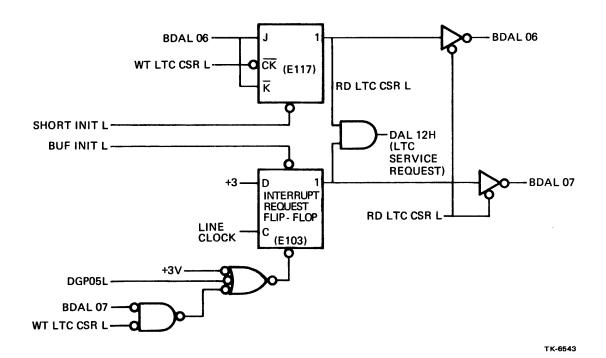

Figure 4-30 Line Time Clock

timing information and an interrupt enable bit to allow the LTC to initiate interrupt sequences. The address of the LKS is fixed at 17 777 546_8 . The monitor bit (Bit <07>) provides the softwaare with a means of measuring time in a non-interrupt mode. This bit of the register is placed on BDAL<07> when read. It is set once for each cycle of the ac power or after a system Init. The program clears the monitor bit after noting that it was set. The monitor bit is cleared when either of the following conditions occur:

- GPO code = 5, which results in the signal DGPØ5 L. The microcode issues GPO 5 after honoring an LTC interrupt.
- Program writes a zero into the bit (the program cannot set the bit).

The LTC interrupt enable bit (Bit <06>) is a read/write bit which allows the LTC to generate periodic interrupt sequences. This bit is written when WT LTC CSR L is asserted. System Initialization (BUF INIT L) clears this bit. This bit of the register is placed on BDAL <06> when read. Both bits in the LKS are read when RD LTC CSR L is asserted. The LTC interrupt request logic consists of the 'ready' flip-flop and an and gate. The flip-flop is set on the trailing edge of LINE CLOCK. The interrupt request is then presented at service time directly to the chip set on DAL <12>. The hardware normally required to arbitrate the interrupt and generate a vector has been replaced by microcode in the chip set. The interrupt vector is fixed at 100_8 by the microcode.

4.9 DISPLAY REGISTER

Two LEDs contained on the CPU module are used to implement a display register. The register is located at address 17 777 570 and is write-only. Any attempt to read this register will result in a timeout.

The display register consists of two flip-flop (E34) located on K12. The flip-flops receive BDAL $<\emptyset1:\emptyset\emptyset>$ and are clocked by the signal K9 WT LIGHTS L from the internal address decoder. The flip-flops when set directly drive the LEDs. The LEDs contain internal current limiting resistors.

INTERRUPT REQUEST LOGIC
The interrupt logic enables SLU1, and SLU2 and the Line Time Clock
(LTC) to interrupt the processor and initiate a service routine.
The interrupt logic for SLU 1 is shown in Figure 4-31, the
interrupt request logic for SLU 2 is shown in Figure 4-32 and the
LTC interrupt logic has been described in paragraph 4.8. Each of
these devices will direct the processor to the correct routine by
generating the appropriate vector. Table 4-11 lists the interrupt
vectors which correspond to each device interrupt.

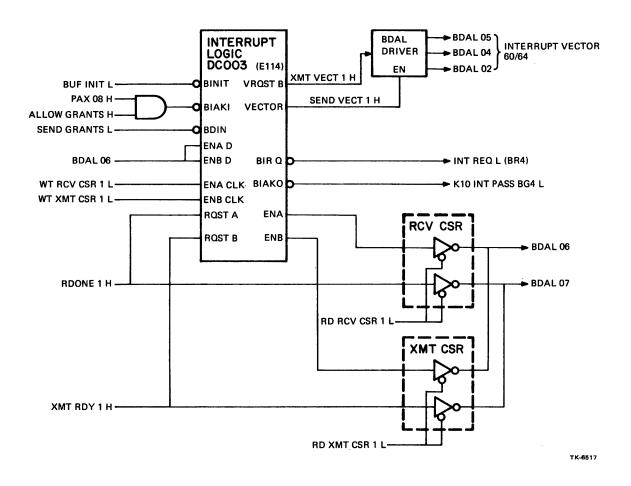

Figure 4-31 SLU1 Interrupt Logic

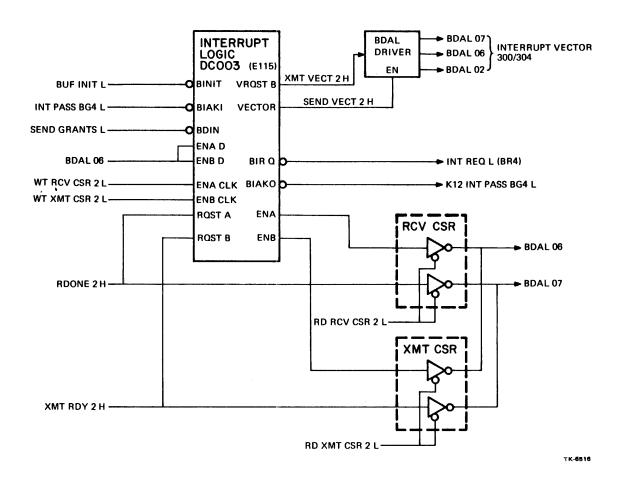

Figure 4-32 SLU2 Interrupt Logic

Table 4-11 Interrupt Vectors

Device	Interrupt Vector	Priority
SLU 1 (Console Terminal) Receiver SLU 1 (Console Terminal) Transmitter SLU 2 Receiver SLU 2 Transmitter Line Clock	060 0648 3008 3048 1008	4 4 4 4 6

The LTC requests an interrupt on a private request line which is equivalent to the highest BR6 request. The SLUs request an interrupt on the public BR4 line.

When the processor has arbitrated an interrupt, other than the LTC, ALLOW GRANTS H will be asserted. Meanwhile, the CPU has encoded a grant signal (BG4-BG7) on the PAX lines and the grant has been latched into the pax latch. For the purpose of this example assume SLU1 is being serviced. The processor will assert BG4 (Bus Grant) by asserting PAX <08> (remember the grants are encoded onto the PAX bits at service time). This indicates that the bus has been granted to at priority 4. Since SLU1 requested the interrupt, it will use the BG to initiate its interrupt sequence. If SLU 1 did not require an interrupt, KlØ INT PASS BG4 L would be asserted passing the grant to SLU 2. SLU 2 will generate K12 INT PASS BG4 L if it does not require an interrupt. This daisy chain effect establishes interrupt priorities for devices at the same BR level. Whoever accepts the grant will then generate BUS SACK acknowledging receipt of the BUS GRANT. and MSYN will eventually be cleared by the previous bus master indicating that the bus is free (from the previous bus cycle). SLU 1 will now assert BBSY indicating that it is the new bus master.

SEND VECT 1 H will be asserted since SLU 1 requested the interrupt. SEND VECT 2 H will be asserted if SLU 2 requested the interrupt. This places the appropriate interrupt vector on the BDAL. XMT VECT 1 H (SLU 1) or XMT VECT 2 H (SLU 2) will be asserted if the respective transmitter caused the interrupt. XMT VECT 1 H (SLU 1) or XMT VECT 2 H (SLU 2) will not be asserted if the receiver caused the interrupt. SSYN will then be asserted by the CPU after it has read the interrupt vector. The interrupt vector and BUS BUSY are then cleared by the device and the processor clears SSYN. This indicates that the interrupt sequence has been performed satisfactorily.

4.11 INTERRUPT ERRORS

Two errors may occur during the processing of a interrupt. The errors are SACK timeout and Vector timeout.

4.11.1 SACK Timeout

SACK (Selection Acknowledge) informs the CPU that a device has accepted the bus grant issued by the CPU. After issuing a grant the CPU must receive SACK before it can continue. Two conditions may cause a failure of SACK being sent:

- 1. No real device requested the interrupt. The request could have been caused by noise or a glitch on the BR line.
- 2. A real device had requested an interrupt but removed its request before the bus grant was sent.

When this condition is present the NO SACK Timeout one shot, E99 (Kl0), times out after 25 us and issues Kl0 BUS SACK L. The CPU now proceeds to get an interrupt vector. This action will also fail.

4.11.2 Vector Timeout

A device signals the availability of its interrupt vector by asserting BUS INTR L. If the device requesting an interrupt is defective or a non-existent interrupt is being serviced no vector is given to the CPU. When this happens the CPU waits for the BUS INTR L which indicates that a vector has been asserted. Since no vector is asserted the CPU could wait forever. However, because the vector is not asserted SSYN is not generated and the SSYN one shot, E62 (K1), times out (25 us) and resets the base machine.

The resulting Bus Error from the vector time out does not trap through 4 because prior to attempting to fetch the vector the microcode sets an internal flag. When this flag is set and a Bus Error occurs no action is taken and the CPU continues as if the interrupt had never been processed.

5.1 INTRODUCTION

The PDP-11/24, like other PDP-11 processors, generates a 16-bit address. The 16-bit address is able to specify 64K byte addresses (32KW). This address differs from the 22-bit address (2048KW) used by the PDP-11/24 to address main memory: thus, the 16-bit processor generated addresses are called Virtual Addresses (VA) and the 22-bit memory addresses are called Physical Addresses (PA). It is the function of the Memory Management Unit (MMU) to convert a 16-bit VA to a 22-bit PA. This is called relocation.

The 22-bit addresses (PA) used by the PDP-11/24 allow a possible address space of $2048\,\mathrm{KW}$. This address space is called Physical Address Space. Figure 5-l shows how Physical Address Space is divided.

- 1. UNIBUS References UNIBUS references access the upper 128KW of Physical Address Space, 17 000 000 17 777 7778, which correspond to UNIBUS addresses 000 0008 777 7778. UNIBUS references include the following:
 - a. The Peripheral Page, which is reserved for UNIBUS device registers and consists of the upper 4KW of UNIBUS references.
 - b. The remaining 124KW of UNIBUS space may be used by UNIBUS devices to access memory.
- 2. Memory References Memory references include PAs from 00 000 000 through the system size boundary which is the highest address in the system main memory.
- 3. Non-Existent Memory Non-existent memory includes the PAs from the system size boundary plus one through 16 777 777 $_8$.

The main function of the MMU is address relocation and protection. The MMU performs address relocation by dividing the 32KW virtual address space into 8 pages of 4KW each. Each page may then permit access to all or only a portion of its 4KW physical address space. In addition, each page may be protected by allowing it to be read only. Another form of protection is that which does not allow the processor to access physical addresses which are not mapped in its current mode of operation, Kernel or User. These features provide protection by allowing each user in a multi-programming environment access to only those pages assigned to that user.

It is often desirable to load a program into one area of physical memory and execute it as if it were located in another area of memory, e.g., when several user programs are simultaneously stored in memory. When any one program is running, it must be accessed

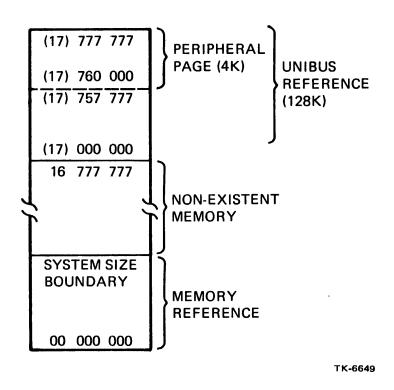

Figure 5-1 Physical Address Space

by the processor as if it were located in the set of addresses beginning at 000 0008. This is possible via relocation. When the processor accesses Virtual Bus Address 000 0008, a base address is added to the virtual address and the physical address produced points to location of the program. Typically this base address is added to all references while the program is running. An appropriate base address is used for each of the programs in memory.

Memory Management specifies relocation on a page basis, which allows a large program to be loaded into nonadjacent physical pages in memory. This ability eliminates the need to shuffle programs to accommodate a new one. It also minimizes unusable memory fragments, thus allowing more users to be loaded into a specific memory size.

A program and its data can occupy as many as 8 pages in memory. The size of each page may vary and can be any multiple of 32 words up to 4096 words in length. This feature allows small areas of memory to be protected, i.e., stacks, buffers, etc., and also allows the last page of program, exceeding 4K words, to be of adequate length to protect and relocate the remainder of the program. As a result, the memory fragmentation problem inherent with fixed-length pages is eliminated. The base address of each page can be any multiple of 32 words in the Physical Address space, thus ensuring efficient use of main memory. The variable page length also allows the pages to be dynamically changed at runtime.

Memory Management provides two separate sets of pages: one set for use by the processor while it is in Kernel mode and another for use in the User mode. These sets of pages increase system protection by physically isolating User programs from the Kernel program. The separate relocation register sets also greatly reduce the time necessary to switch context between Kernel and User mapping. The two sets of registers also aid the user in designing an operating system that has clearly defined communications, is modular, and is more easily debugged and maintained.

5.2 RELOCATION

Relocation may be performed in one of the three modes. While relocation is off, the processor is said to be operating in the 16-bit mode. The virtual address is passed directly to the physical address bus and then main memory with the exception of virtual addresses in the range 160~000 through 177~777. These addresses are passed to the Peripherals Page located at physical addresses 17~760~000 through 17~777~777 (See Figure 5-2).

The processor operates in the 16-bit mode whenever the MMU chip is absent or disabled, or the processor has just been initialized by a console "GO" command or by a RESET instruction.

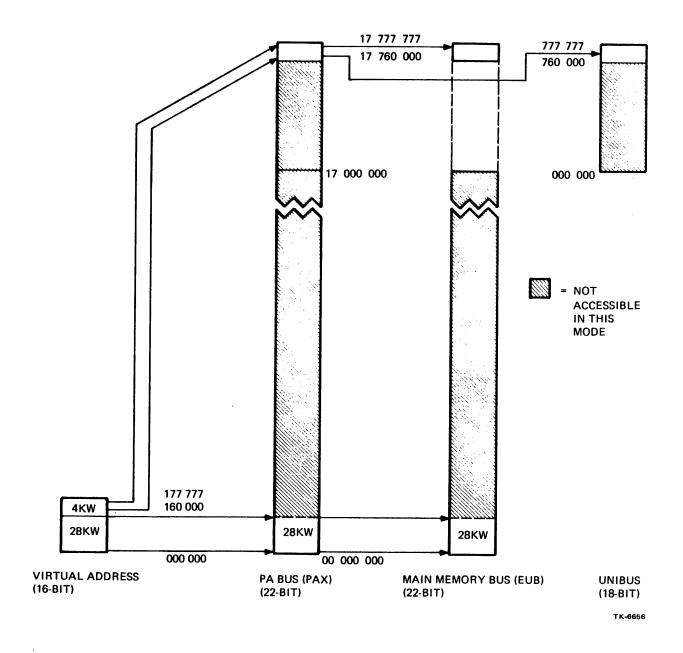

Figure 5-2 16-Bit Mode

The processor may also operate in either the 18-bit or 22-bit relocation modes. In the 22-bit mode relocation is fully enabled and the MMU can map virtual addresses anywhere in physical address space. In the 18-bit mode the MMU can only map the first 124KW of main memory and the Peripherals Page. In the 18-bit mode the PDP-11/24 memory management function is compatible with earlier PDP-11 processors (e.g., PDP-11/34, 11/40 and 11/60) employing memory management. Figures 5-3 and 5-4 illustrate the 18 and 22-bit modes of operaton.

A switch selectable submode of 16-bit and 18-bit mapping exists. Certain user programs written for earlier processors require physical adddresses in the range 000 0008 through 757 7778 to be passed to the UNIBUS, rather than just the main memory bus. Typical applications involve multi-ported UNIBUS memory, UNIBUS windows, and some graphics processors. To allow these earlier programs to run on the PDP-11/24 E124-56 should be in the OFF position thereby forcing all physical addresses to the UNIBUS as well as the memory bus. When this action occurs the 22-bit PA is truncated to 18-bits for use on the UNIBUS. Figures 5-5 and 5-6 illustrate this action.

NOTE

Use of this switch is not recommended if the processor is operating in the 22-bit mode. Severe double addressing problems can occur. It is recommended to use direct programmed access to the UNIBUS when in the 22-bit mode.

Switch S6 should be on for normal operation of the PDP-11/24.

5.2.1 Address Mapping

The basic information needed for the construction of a PA comes from the VA which is illustrated in Figure 5-7, and the appropriate APR set.

The Virtual Address consists of:

- 1. The Active Page Field (APF) This 3-bit field is used to determine which of the eight pages this VA belongs to, and thus which of the eight PARs will be used to form the PA.
- 2. The Displacement Field (DF) This 13-bit field contains an address relative to the beginning of a page. This permits page lengths of up to 4K words. The DF is further subdivided into two fields as shown in Figure 5-8.

The Displacement Field consists of:

1. The Block Number (BN) - This 7-bit field is interpreted as the block number within the current page.

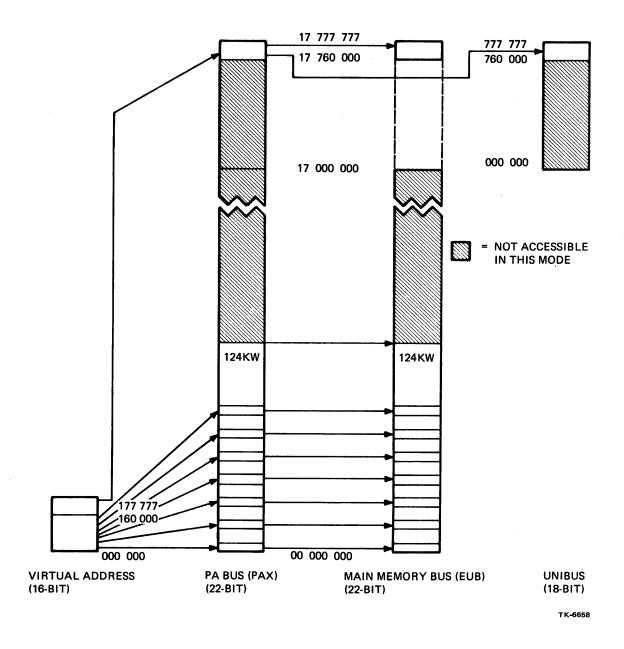

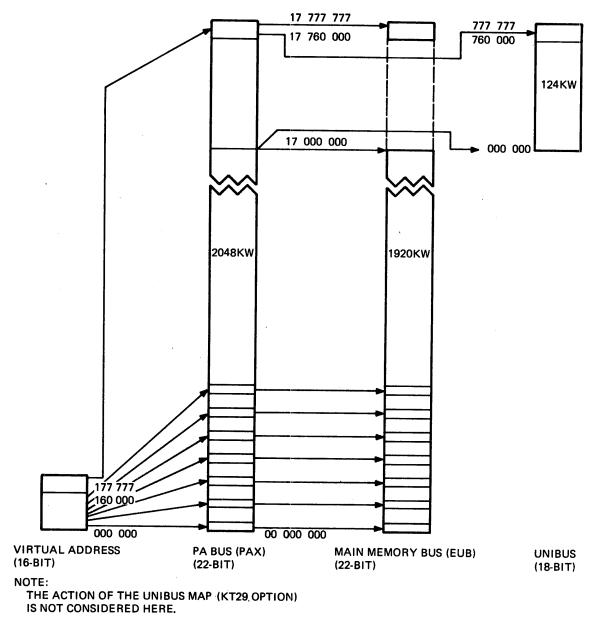

Figure 5-3 18-Bit Mode (Typical Case)

TK-6654

Figure 5-4 22-Bit Mode (Typical Case)

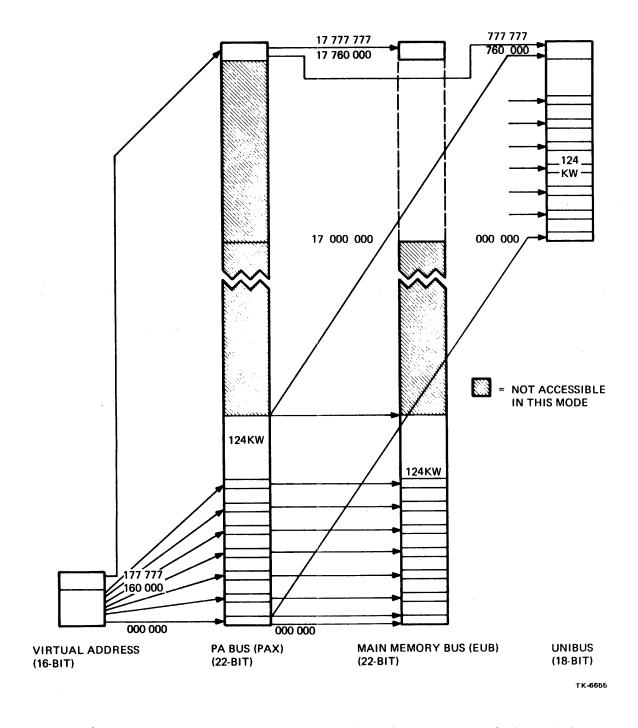

Figure 5-6 18-Bit Mode, E124, S6 OFF (Special Mode) (Typical Case)

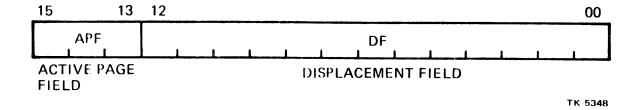

Figure 5-7 Interpretation of VA

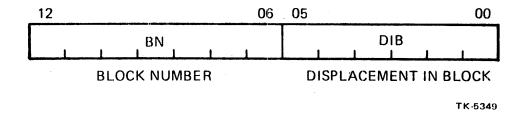

Figure 5-8 Displacement Field

2. The Displacement in Block (DIB) - This 6-bit field contains the displacement within the block referred to by the Block Number (BN).

The remainder of the information needed to construct the PA comes from the 16-bit Page Address Register and specifies the starting address of the memory page. The PAR is actually a block number in physical memory, e.g., PAR=3 indicates a page starting at the 96th (3x32) word in physical memory.

The formation of the PA is illustrated in Figure 5-9.

The logical sequence involved in constructing a PA is as follows:

- The Active Page Field of the VA is used to select a PAR (PARØ-PAR7).
- 2. The selected PAR contains the starting address of the currently active page as a block number in physical memory.
- 3. The Block Number (BN) from the VA is added to the PAR to yield the number of the physical block in (PBN) memory which will contain the PA being constructed.
- 4. The Displacement in Block (DIB) of the VA is joined to the physical block number to yield a 22-bit PA.

5.2.2 Address Translation

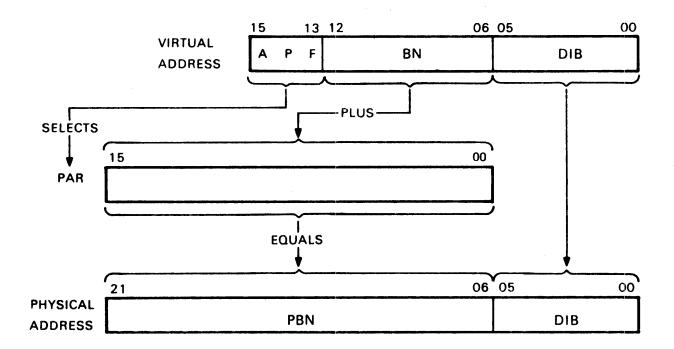

The Memory Management Unit is able to relocate 16-bit addresses in one of two modes:

- 1. 18-bit mode This mode of operation generally provides program compatibility with smaller PDP-11 processors, i.e., the PDP-11/34,35,40,45,55,60.
- 2. 22-bit mode This mode of operation generally provides compatibility with larger PDP-11 processors, i.e., PDP-11/44, $PDP-11/7\emptyset$.

Figure 5-10 is a block diagram of the memory management section of the MMU.

5.2.2.1 18-bit Mapping -- Refer to Figure 5-3. In 18-bit mapping the VA is added to bits <11:00> of the selected PAR to generate the PA. This address mode has a range of 128KW. The physical address space consists of 124KW (00 000 000 8 - 00 757 777 8) and the 4KW peripheral page (17 760 000 8 - 17 777 777 8).

18-bit mapping is enabled when bit 4 of SR3 is clear (18-bit mapping) and bit 0 of SR0 is set (relocation enabled). The MMU uses bits $\langle 15:13 \rangle$ of the VA to select the appropriate PAR-PDR pair.

TK-6652

Figure 5-9 Construction of PA

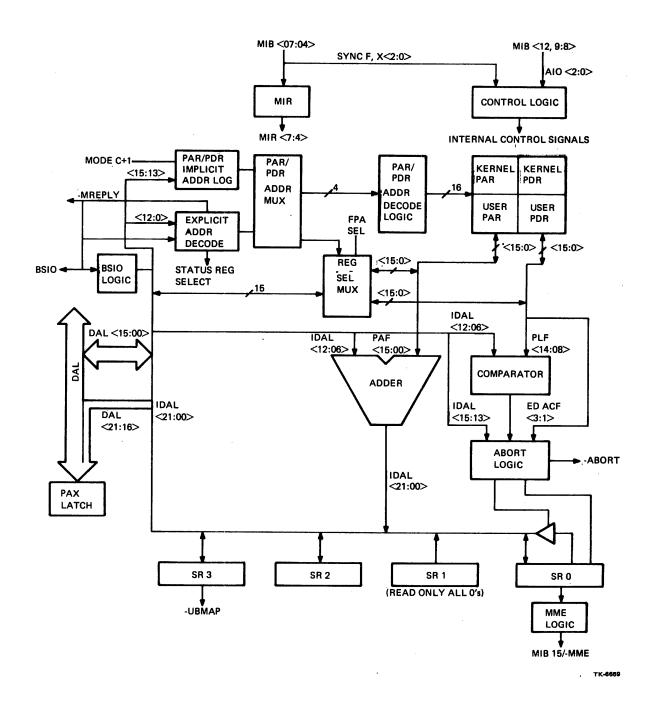

Figure 5-10 MMU Block Diagram

After selecting the PAR the MMU adds bits <12:06> of the VA to bits <11:00> of the PAR (bits <15:12> are not used in 18-bit mapping and are masked off prior to the adder in the MMU). The sum of PAR <11:00> and VA <12:06> create PA <21:06> which are driven, along with bits <05:00> of the VA, onto the DAL to create the 22-bit physical address. If bits <17:13> of the PA are all ones a reference to the Peripheral Page is intended by the program. When this condition exists the MMU asserts -BSIO which forces logic on the CPU module (K7) to force bit <21:18> of the PA to ones. If bits <17:13> of the PA are not all ones bits <21:18> of the PA are set to 0.

Figure 5-11 shows the case of an 18-bit PA that is not a UNIBUS reference, i.e., bits <17:13> are not all 1s. In this case bits <21:18> of the PA are set to zeros, which causes a memory reference.

Figure 5-12 shows the case of an 18-bit relocated address that is a UNIBUS I/O reference, i.e., bits $\langle 17:13 \rangle$ are all 1s. In this case bits $\langle 21:18 \rangle$ of the PA are changed to 1s, which causes a UNIBUS reference.

5.2.2.2 22-Bit Mapping -- Refer to Figure 5-4 and 5-13. In 22-bit mapping the VA is relocated in the same manner as 18-bit mapping, but the full 16-bits of the PAR are passed to the adder in the MMU. Thus all addresses from 00 000 000 $_8$ - 17 777 777 $_8$ can be generated. In the 22-bit mode no special consideration of I/O page references is taken since the required physical address range (17 760 000 $_8$ - 17 777 777 $_8$) can be generated directly.

22-bit mapping is enabled when bit 4 of SR3 is set (22-bit relocation) and bit 0 of SR0 is set (relocation enabled). As with 18-bit mapping bits <05:00> of the VA are passed through the MMU unaltered to become bits <05:00> of the PA. VA <15:13> are used to select a PAR. The contents of the PAR are added to bits <12:06> of the VA to create bits <21:06> of the PA.

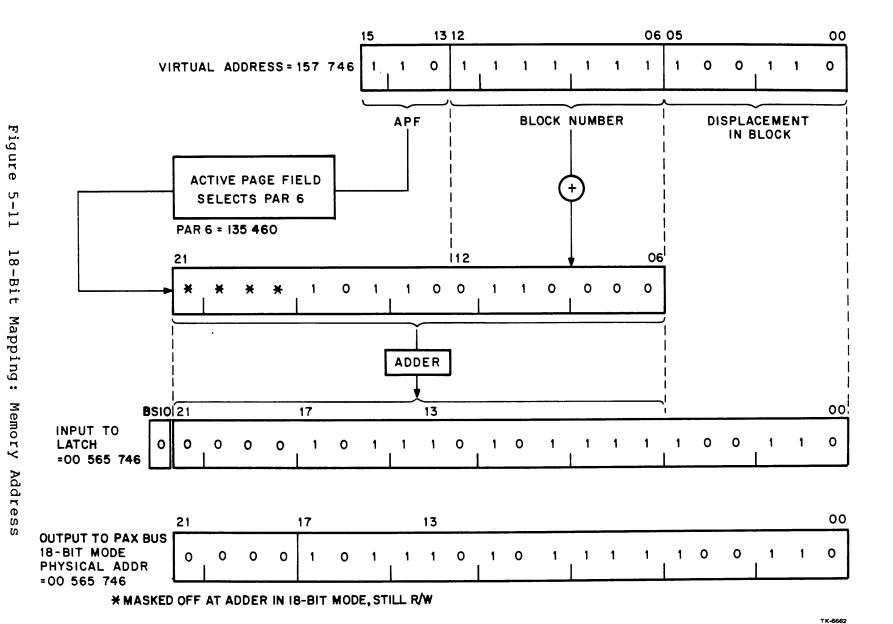

5.2.2.3 Physical Addressing -- After the 22-bit address is generated, steering logic in the CPU controls its routing (see Figure 5-14). Two modes of addressing are possible in the PDP-11/24:

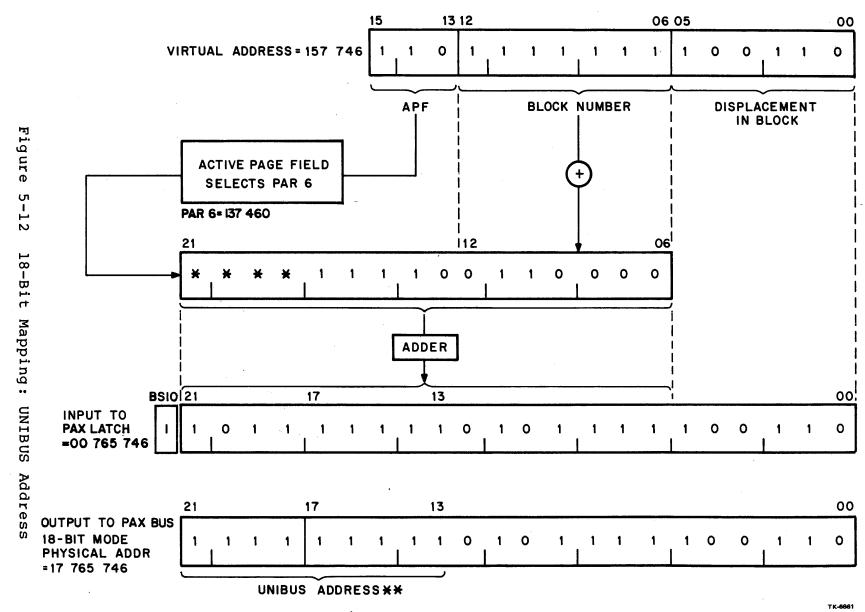

- 1. Normal 22-bit addressing mode E124 S6 closed
- Special 18-bit compatability mode E124 S6 open (22-bit addressing generally impossible)

In the normal mode the CPU generates a 22-bit physical address on the PAX bus (Physical Address Extended).

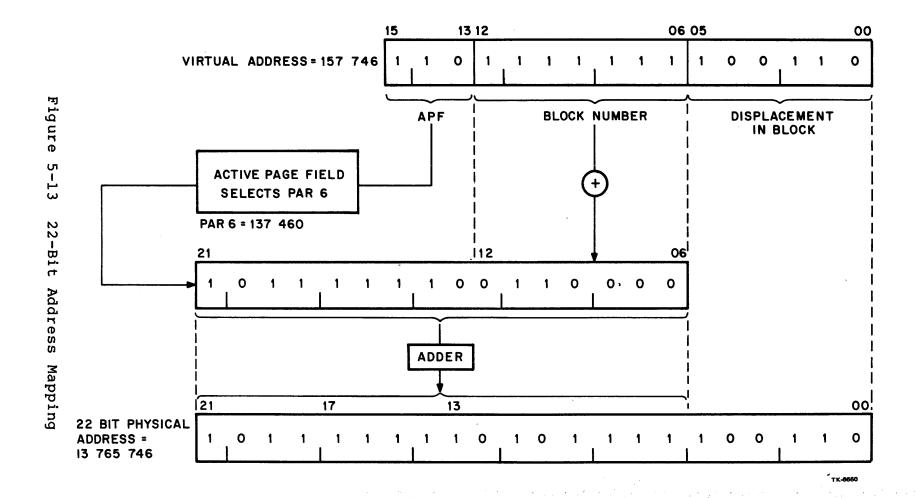

The processor will then make two decisions about the physical address:

1. Is it in the upper 128KW of address space?

* MASKED OFF AT ADDER IN 18-BIT MODE, STILL R/W
** PAX ADDRESS BITS <21:16> FORCED TO 13.

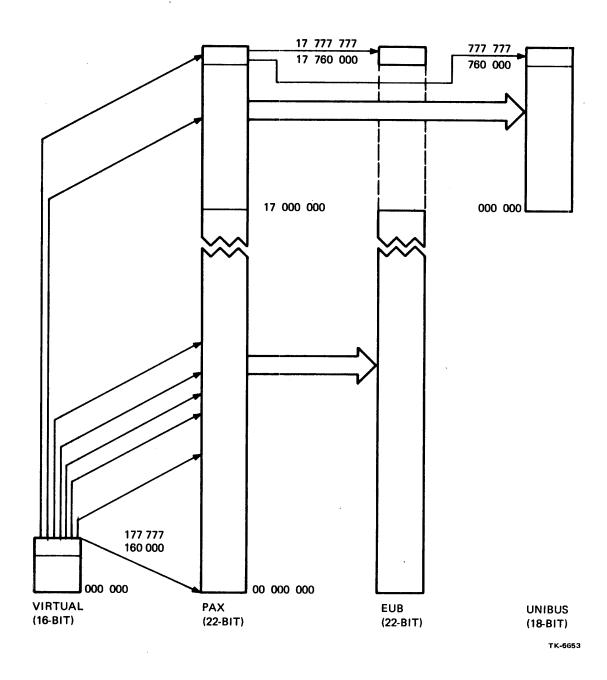

Figure 5-14 PDP-11 Address Space

2. Is it in the upper 4KW of address space?

Addresses below the upper 128KW are sent only to the memory bus.

Addresses in the upper 128KW of address space (Figure 5-10) are sent to the UNIBUS. When this happens PAX bits <21:18> are dropped because the largest address the UNIBUS can use is 18-bits. Addresses in the lower 124KW of UNIBUS space are not sent to main memory. Therefore the maximum amount of memory that can be accessed is 2048KW - 128KW = 1920KW.

Addresses in the upper 4KW of memory are I/O page addresses. These addresses are sent to the UNIBUS and Main Memory. I/O devices are not normally located on the memory bus but because the memory parity CSRs are located in this address range they can be accessed by sending I/O page addresses on the memory bus.

In the special mode – 18-bit compatibility the CPU forces all references in the physical address space to also be sent to the UNIBUS (Figure 5-15). This mode is used to simulate the operation of the PDP-11/34.

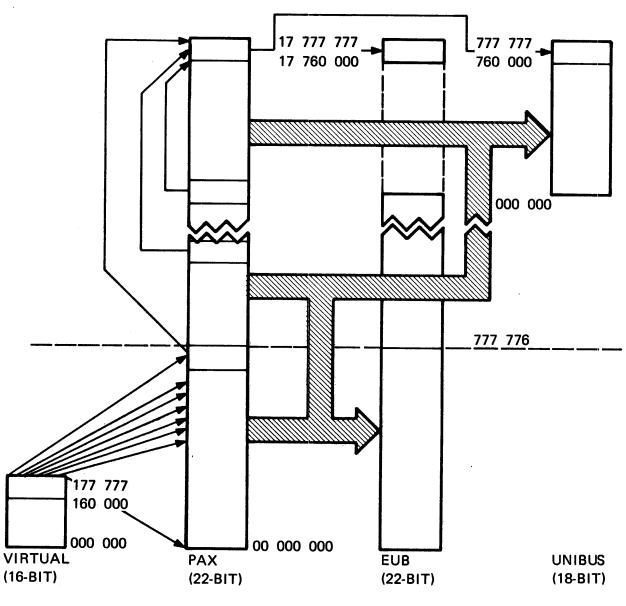

NOTE

Care should be taken when using the PDP-11/24 in the 18-bit compatibility mode. Dual addressing problems will occur if an address above 777 7778 is generated. For example address $\emptyset1$ 777 651_8 will access UNIBUS address 777 651_8 as well as main memory location $\emptyset1$ 777 651_8 .

5.3 MEMORY MANAGEMENT REGISTERS

The memory management chip provides two sets of Active Page Registers (APRs). Each APR consists of a Page Address Register (PAR) and a Page Descriptor Register (PDR). These registers are always used as a pair and contain all the information required to locate and describe the currently active pages for each mode of operation (Kernel and User). One PAR/PDR set is used in the kernel mode, the other in the User mode. The current mode bits or the previous mode bits of the processor status word determine which set will be referenced for each memory access. A program working in one mode can be prevented from using the register set of the other mode to access memory. A specific address in the I/O Page is assigned to each PAR and PDR.

A relocation register reference to any APR with memory management enabled actually causes two words (32-bits) to be accessed at a time. This allows the Page Address Register and the Page Descriptor Register to be available together for relocation cycles. When directly reading or writing a PAR/PDR register, only the register that was specifically addressed by its UNIBUS address is connected to the Data/Address Lines.

TK-6657

Figure 5-15 PDP-11 Address Space, CPU References with 18-Bit Switch OFF

The PAR/PDR registers can be accessed in two ways:

- 1. When directly referenced for external data transfers by their UNIBUS addresses.
- 2. When referenced by a virtual address during a relocation cycle.

Each PAR/PDR register has a unique memory address in the I/O page (Table 5-1). PAR/PDR direct UNIBUS addressing is triggered at the beginning of a system bus operation if the physical address on the Data Address Lines (DAL) during the address microinstruction cycle is the address of one of these registers and BSIO H (Bank Select I/O) is true, indicating an address in the I/O page. This physical address is derived from one of three possible sources:

- 1. The virtual address received from the data chip during the first half of the address microcycle.
- 2. A relocated virtual address that is generated internally (by the MMU chip) during the second half of the cycle.
- 3. An externally generated physical address (console ODT mode) that is received during the second half of the address microcycle.

The physical address pointer is used to control register selection during all subsequent I/O transfers until the system bus operation ends. During this time no indirect addressing (relocation) can take place. When in the direct addressing mode, output microinstruction cycles cause the contents of the DAL to be written into the addressed word or byte of an MMU register. However, the W-bit (Written Into) of the PDR is only modified indirectly. It is cleared when either register of the APR set is written into and is set when the bank of virtual memory under control of the APR is written into. Direct UNIBUS references are the only way in which other PAR/PDR register contents can be altered.

Active Page Registers are addressed as PAR/PDR register pairs during address relocation cycles. The register pair is selected by bits <15:13> of the virtual address and the selected mode (User/Kernel) sent by the data chip. PAR/PDR register pairs cannot be altered by indirect references (except for the W-bit).

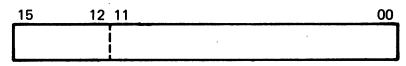

Table 5-1 is a list of address assignments.

5.3.1 Page Address Register (PAR)

Figure 5-16 illustrates the page address register which contains the 16-bit base address of the page. This 16-bit displacement is added to bits <12:06> of the virtual address received from the data chip to create PAX<21:06> of the relocated physical address (Figure 5-9) PAX<05:00> are the same as bits <05:00> of the virtual address.

Table 5-1 PAR/PDR Address Assignments

Kernel Active Page Registers			User	Active Page	Registers
No.	PAR	PDR	No.	PAR	PDR
Ø	17772340	17772300	Ø	17777640	17777600
1	17772342	17772302	ĩ	17777642	17777602
2	17772344	17772304	2	17777644	17777604
3	17772346	17772306	3	17777646	17777606
4	1777235Ø	17772310	4	17777650	17777610

7	17772356	17772316	7	17777656	17777616

BASE ADDRESS OF PAGE

BITS <11:00> USED IN 18-BIT MODE BITS <15:00> USED IN 22-BIT MODE

TK-6650

Figure 5-16 Page Address Register (PAR)

The page address register may be alternatively thought of as a relocation constant, or as a base register containing a base address. Either interpretation indicates the basic function of the PAR in the relocation scheme.

5.3.2 Page Descriptor Registers (PDR)

Figure 5-17 illustrates the page descriptor register which contains information relative to page expansion, page length and access control. Table 5-2 explains the function of the various bits in this register.

5.4 MEMORY MANAGEMENT STATUS REGISTERS

The Memory Management chip contains the four status registers associated with the Memory Management operations. The PDP-11/24 however, does not use all four registers provided. The status registers can be referenced by their UNIBUS addresses (Table 5-3). Status Register \emptyset (SR \emptyset) contains information regarding Memory Management abort conditions as well as the Enable Relocation bit. A Memory Management abort condition is caused during internal address relocation by one of the following:

- An attempt is made to access a non-resident page. This is detected by examining the PDR Access Control Field.
- A write protection violation has occurred. This is detected by examining the PDR Access Control field during write operations.
- 3. A page length error is detected. (An access outside the allowable boundary of the page.)

When an Abort condition occurs the ABORT L output of the MMU chip is asserted during the second half of the cycle in which the relocated address is generated. The assertion of ABORT L resets the control chips (forcing the service micro-state) and generates the MMU ERR service signal which indicates an error in the Memory Management cycle has occured. The asserting of MMU ERR will cause the processor to execute a trap through the vector at 2508, thus notifying the user's program of the MMU Abort.

The abort line is blocked when DMMUS L (Disable MMU Slave) is asserted. DMMUS L disables the MMU's ability to drive DAL<21:00> and the BSIO signal as well. It informs the Memory Management Enable logic that the ensuing relocation operation is being externally controlled and is used to block the MMU from using the chip bus.

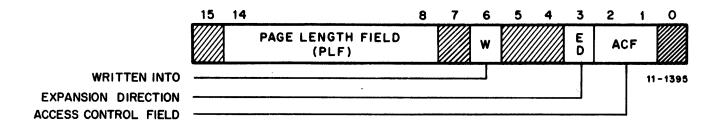

Figure 5-17 Page Descriptor Register (PDR)

Table 5-2 Page Descriptor Register (PDR)

Bit	Descr	iption	
PLF <14:08>	addre page. numbe detec	ssable blo Bits <12 r) are con	Page Length Field specifies the number of ocks (block = 32 words) in the accessed :06> of the virtual address (desired block mpared with the PLF in the comparator to references outside the program defined
W <Ø6>	writt (unle memor set (CPU	en into a ss the rel y manageme during int accesses),	t if any location in the accessed page is after the APR set is initially accessed ocated destination is one of the internal ent registers). Note that it can only be ternally controlled relocation operations not NPRs (DMA). It is cleared when the hat page is directly written.
ED <03>	This bit controls the expansion direction of the page boundary and is used in checking for page length violations.		
	ED=0:	Upward e number Ø	expansion (most normal code) from block to include blocks with higher addresses.
	ED=1:	Downward to inclu	expansion (stacks) from block number 1778 de blocks with lower address.
ACF <02:01>	The two-bit Access Control Field describes the access rights to the page. Any attempt to perform an operation not allowed by the ACF causes an MMU abort. The ACF codes are expanded below:		
	ACF	<02:01>	Function
-	Ø Ø	Ø 1	Abort any access to this page. Allow read accesses, abort any write access to this page.
Mary 1.00 - 1 - 1 - 1 - 1 - 1 - 1 - 1 - 1 - 1 -	1	Ø 1	Abort any access to this page. Allow read or write.

NOTE: All unused PDR bits are read as zeros and cannot be written into.

Table 5-3 Memory Management Status Register Unibus I/O Addresses

Register	Address	Contents
17 777 572	Status Register Ø (SRØ)	Abort information, status information, relocation enable.
17 777 574	Status Register 1 (SR1)	All 0's (Not used in the PDP-11/24)
17 777 576	Status Register 2 (SR2)	Last PC fetched
17 772 516	Status Register 3 (SR3)	22/18 bit mapping mode selection, UNIBUS MAP enable

5.4.1 Status Register Ø (SRØ) Status register Ø contains the Relocation Enable control bit as well as information regarding any Memory Management abort condition. Figure 5-18 illustrates the bit assignments of SRØ and Table 5-4 provides a description of these bits. SRØ bits <06:05,03:01> are updated during every relocation cycle. When a fault occurs SRØ bits <15:13> are set (depending on the error), the mode, page, and all bits in Status Register 2 (SR2) are frozen in order to capture the state of the aborted relocation attempt. Subsequent relocation attempts or aborts will not alter the information present at the first fault. SRØ remains frozen until SRØ bits <15:13> are cleared by direct UNIBUS access or an initialization signal. Direct setting of any of the abort flags will also cause the SRØ bits to be frozen but will not activate the abort output. SRØ is cleared by control signals from the data chip.

5.4.2 Status Register 1 (SR1)

This register is not used in the 11/24. When addressed by its UNIBUS address, all the bits in this register are read as \emptyset and cannot be written into. This register is included to avoid system bus errors if the SRl is referenced.

5.4.3 Status Register 2 (SR2)

SR2 is loaded during a relocation cycle with the 16-bit virtual PC received from the data chip. This occurs on all address cycles when the control information indicates that the current address on the bus is that of an instruction. The contents of SR2 are frozen when an abort flag is set. SR2 is read only.

5.4.4 Status Register 3 (SR3)

The 11/24 only uses two bits of this register, bits $\langle 05:04 \rangle$. Bit $\langle 05 \rangle$ when cleared disables the optional UNIBUS mapping logic and when set enables the UNIBUS mapping logic. Bit $\langle 04 \rangle$ when cleared selects the 18-bit mapping mode within the MMU and when set selects the 22-bit mapping mode in the MMU. Bit $\langle 00 \rangle$ of SR1 then determines whether or not to enable the selected relocation mode. If relocation is not enabled, 16-bit mapping results. This bit is used internally by the MMU. All other bits in the register are read as 0's. SR3 is cleared by the same control signals which clear SR0.

5.5 MICROINSTRUCTION REGISTER (MIR)

Every cycle, MIB $\langle 07:04 \rangle$ are loaded into the microinstruction register. During address cycles the microinstruction register is used to control the relocation operation. The relocation function is temporarily disabled, regardless of the state of the Relocation Enable bit (SR0 $\langle 00 \rangle$), when bit 7 of the microinstruction is set. This will also cause an initialization condition clearing status registers SR0 and SR3 if issued during an output status microinstruction. When bit 5 of the microinstruction is set, Status Register SR2 is loaded with the incoming instruction address.

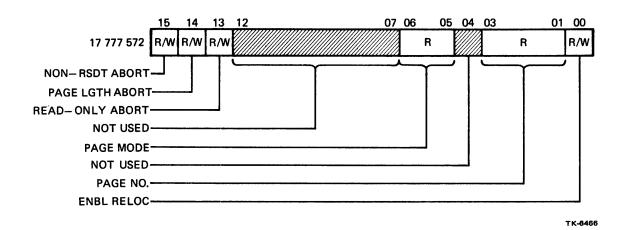

Figure 5-18 Memory Management Status Register \emptyset (17 777 572)

Table 5-4 Memory Management Status Register Ø (SRØ)
Bit Description

Bit	Description
<15> Non-resident Abort (ANR)	This bit is set when an attempt is made to access a page with an Access Control Field in the PDR of 00 or 10. The ANR bit can be read or written.
<14> Page Length Abort (APR)	This bit is set when the page length boundary is exceeded. The APR bit can be read or written.
<13> Read-Only Abort (ARO)	This bit is set when an attempt is made to write a page with an Access Control Field in the PDR of Øl. The ARO bit can be read or written.
<12:07>	These bits are read as \emptyset and cannot be written into.
<06:05> Mode	These bits are set to ll if a relocation takes place while in User mode and set to 00 if a relocation takes place while in Kernel Mode. The mode bits are read only.
<04>	This bit is read as \emptyset and cannot be written into.
<03:01> Page Number	These bits contain the page number of the virtual address. The page number bits are read only.
<00> Enable	This bit enables the Memory Management function when set. The enable bit can be read or written.

5.6 MEMORY MANAGEMENT ENABLE (MME) LOGIC

The MME logic generates the MME L control output (MIB <15>) during internally controlled relocation cycles. It also receives and interprets the Disable MMU Slave (DMMUS L) control input to detect externally controlled relocation cycles.

 ${\tt MME}$ L is generated during the first half of the address microinstruction cycle (while other control information is on the MIB) if a relocation operation is to take place. MME L asserted causes external timing to delay MCLK until the relocation operation is complete and informs the data chip during address cycles that it must update its PSW explicit addressing logic with the new address information. MME L can be driven by external logic. If DMMUS L is not asserted and Memory Management is not internally enabled the virtual address from the data chip is not relocated. When Memory Management is internally enabled then the virtual address is relocated for internal and external use and MME L is asserted. Note that Memory Management cycles can be disabled by either bit $\langle \emptyset\emptyset \rangle$ of Status Register \emptyset (SR \emptyset) or under microprogram control by MIR <07>. Assertion of DMMUS L during an address cycle informs the MME logic that the following relocation operation is externally controlled. Any internally generated abort conditions are ignored and the DAL receive the new address for explicit address decoding.

BSIO H (Bank Select I/O) will be asserted when an internally relocated address accesses the I/O page of memory address space. The BSIO output is enabled during the second half of the relocation cycle unless an abort condition exists or the DMMUS L input is asserted.

5.7 MEMORY MANAGEMENT TIMING

A single clock MCLK controls all LSI chip functions including the MMU chip. An explanation of the MMU timing is contained in Paragraph 4.2.1.2 of this manual.

5.8 MEMORY MANAGEMENT CONTROL SIGNALS

Three groups of control inputs are used by the MMU: Address I/O control (AIO <02:00>), Sync flip-flop (SYNCF), and X-Control (X <02:00>). The 3-bit Address I/O control inputs (MIB <12,09:08>) indicate the operations if any for the present microinstruction cycle. Section 4.3.2 provides a description of the AIO control bits. The MMU chip uses the address cycle information to initiate relocation operations, and the data cycle information to control accesses to its internal registers.

The Sync flip-flop (SYNCF) control input (MIB <07>) signifies that a system bus cycle is in progress. This signal is set by the data chip when the bus cycle starts and is kept active for the duration of the cycle. It is used to maintain the state of the internal SYNC flip-flop and to control the PAR/PDR/SR0-3 UNIBUS addressing logic.

The 3-bit X-control inputs (MIB <06:04>) encode control information from the data chip. Paragraph 4.3.2 provides an explanation of these three bits.

6.1 INTRODUCTION

The KT24 UNIBUS map option is a hex-height, multi-layer module that contains the logic necessary to implement a UNIBUS map, M9312 compatible bootstrap and a voltage monitor for the PDP-11/24. The KT24 UNIBUS map option is installed in the second slot of the PDP-11/24 processor backplane. Figure 6-1 shows a functional block diagram of the KT24 UNIBUS map option. The following paragraphs discuss the operation of the KT24 UNIBUS map option.

6.2 UNIBUS MAP

The UNIBUS Map is the interface between the UNIBUS and main memory. It responds as a slave device to UNIBUS signals and is used to convert 18-bit UNIBUS addresses to 22-bit memory addresses.

UNIBUS address space is 128KW of which the top 4KW addresses are reserved for the CPU and I/O registers. This upper 4KW of UNIBUS address space is called the I/O page (Figure 6-2). The lower 124KW of UNIBUS address space can be used by the UNIBUS map to reference physical memory.

The UNIBUS map consists of 32 mapping registers (K4-6), a 21-bit adder (K4-8), and associated logic. The mapping registers are 21-bits wide and can be accessed in two different ways:

- Direct Access The mapping registers are accessed via their UNIBUS address. Because the mapping registers are 21-bits wide, two UNIBUS transactions are required for each read or write of the registers.
- 2. Indirect Access When the UNIBUS map is enabled, the upper 5-bits of the UNIBUS address are used to select the appropriate register to be used in relocating the 18-bit UNIBUS address.

The 21-bit wide UNIBUS map registers are allotted 64 addresses in the I/O page (Table 6-1). It should be noted that the last mapping register (addresses 17 770 374 and 17 770 3768) can be read or written, but cannot be used to map UNIBUS addresses because it would be used by addresses in the range of the I/O page (17 760 0008 - 17 777 7778).

The UNIBUS map does relocation by adding one of 31 UNIBUS map registers, which contain a relocation constant, to bits <12:01> of the UNIBUS address to create a 22-bit physical address (PA). The 22-bit PA is used to reference physical memory. When the UNIBUS map is disabled, its operation is transparent to the user and the incoming UNIBUS address is used to reference the first 124KW of physical memory and the I/O page.

^{*}Can be read or written into, but not used for mapping.

Figure 6-3 shows a block diagram of the UNIBUS map and its associated control logic.

6.2.1 MSYN Steering

The MSYN Steering logic located on K1-3 is used to control the generation of MEM MSYN in the PDP-11/24 when the KT24 UNIBUS map is present in the system. The MSYN Steering logic controls MEM MSYN in the following ways.

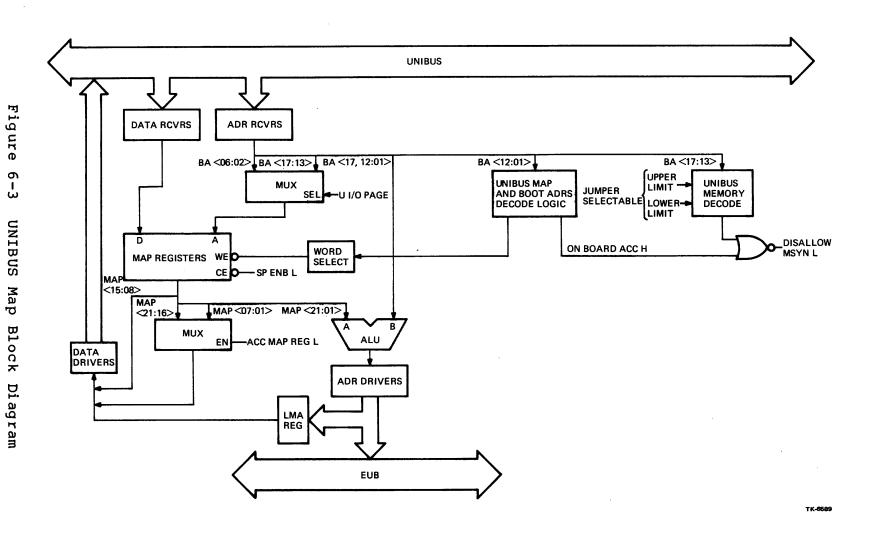

- When the UNIBUS map is disabled, the MSYN steering logic performs the following functions:
 - Determine if the CPU or a DMA device is performing the transfer.
 - Allow the assertion of MEM MSYN.
- When the UNIBUS map is enabled, the MSYN steering logic performs the following functions:
 - Determine if the CPU or a DMA device is performing the transfer.
 - Delay the assertion of MEM MSYN to allow the UNIBUS map to generate the Physical Address.
 - Enable the relocated address onto the EUB.
 - Strobe the relocated address into the Last Mapped Address (LMA) register.
- 3. Disallow the assertion of MEM MSYN when one of the KT24 UNIBUS Map Option I/O page registers is accessed.

6.2.2 Map Control

The map control logic (K1-4) is used to control the reading and writing of the 32 map registers and the Last Mapped Address (LMA) register. The control logic consists of the UNIBUS map and boot address decode PLA (E92), a delay line (E31), and associated read/write and buffer control logic. The address decode PLA (E92) decodes the UNIBUS address to determine if a read or write of a map register or the LMA register is to be performed. If a read or write of one of these registers is intended, the PLA will assert ON BOARD ACC H and depending on the register to be accessed ACC HI LMA L, ACC LO LMA L, or ACC MAP REG L. ON BOARD ACC H is used to accomplish the following during a read/write of the map and LMA registers.

- 1. Assert DISALLOW MEM MSYN. This keeps MSYN, intended for the map or LMA registers, from being sent to memory.
- 2. ON BOARD ACC H is ANDed with BUS MSYN H to generate VALID ADD H which loads counter E81 with a three (3) and causes the input of delay line E31 to be asserted. The delay

6-6

line is used to negate ENB WRITES H during a write operation, assert ENB READ DAT L during a read operation, and assert UBI SSYN H.

Figure 6-4 shows the relationship of these signals to VALID ADD H.

Figure 6-5 shows the logic used to select whether the High word or Low word of the selected register is to be read or written.

6.2.3 Map Addressing and Relocation

Relocation expands the 18-bit UNIBUS address to the 22-bit main memory address. This allows the UNIBUS to access any location in main memory. This relocation or mapping of addresses is done by adding the contents of one of the mapping registers to bits (12:01) of the incoming UNIBUS address.

All mapping registers in the UNIBUS map are 21 bits wide. A 22nd bit, which is not writable and is always read as zero, acts as the lowest-order bit for each register. Each register specifies the 22-bit base PA of a 4K page residing on any word boundary in memory. The reason for using word boundaries is that the mapping logic does not recognize if a byte operation is being executed.

Figure 6-6 illustrates the construction of a PA by the UNIBUS map. Bits <17:13> of the 18-bit UNIBUS address select a map register. The remaining bits <12:00> of the UNIBUS address are used as an offset into the page to which the mapping register is pointing.

When an address is taken from the UNIBUS, the mapping register is automatically selected and the contents read out. Then the 22-bit base address contained in the selected map register is added to the 12-bit offset in the UNIBUS address to form the PA. This mapping function is very similar to that performed by memory management.

The program controls this process both by selecting the contents of the mapping registers and by its ability to enable and disable the UNIBUS map relocation function. Since the 32 UNIBUS map registers may be accessed directly from the UNIBUS, a sophisticated DMA device could also manipulate them. Thus, virtually unlimited-length transfers may be performed.

The UNIBUS map is enabled by the assertion of UBMAP L (bit <05> of SR3). The UNIBUS address lines are received and buffered by logic on K1-5. When a mapping operation is being done, a multiplexer (E69,E62) selects bus address bits BA <17:13>, to generate the map register address RAM A <4:0>. The output of the selected map register, MAP <21:01>, is then sent to the adder, which is made up of ALU's E36, E35, E34, E42, E44 and carry generators E43 and E45, where it is added to BA <12:01> to create MA <21:01>. MA <21:01>, along with BA<00> and control bits BCl and BC0, are used to create the PA and control information. The relocated physical address is asserted on the memory bus (EUB) via buffers E16, E25 and E33 and strobed into the LMA register.

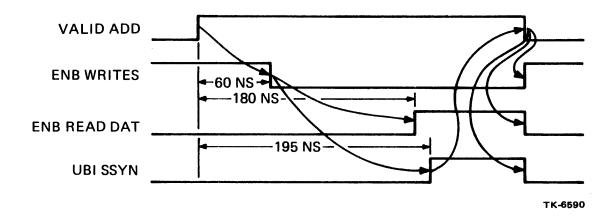

Figure 6-4 Map Control Timing

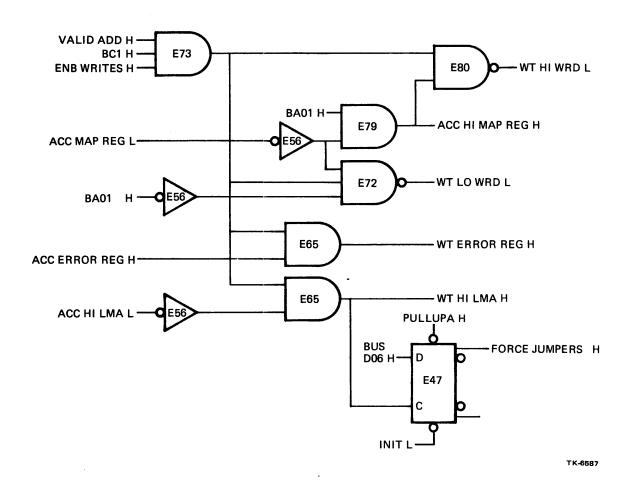

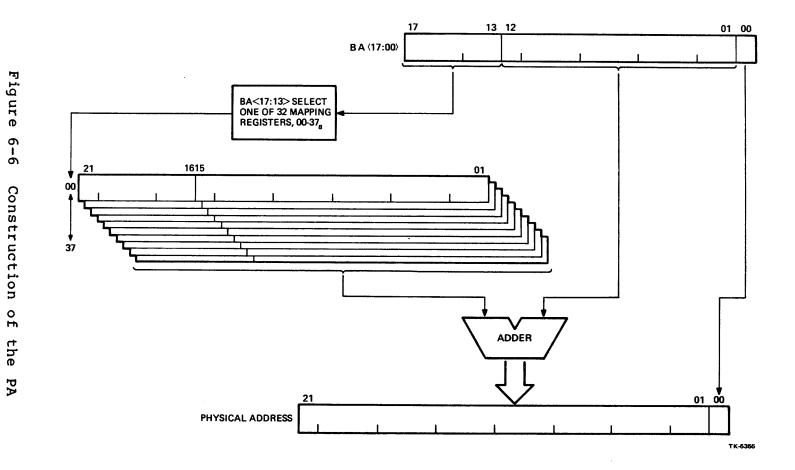

Figure 6-5 Word Control

6.2.4 Addressing Limits

There are 31 mapping registers which can be accessed indirectly by the UNIBUS for relocation. The actual number in use is determined by two sets of five jumpers (Kl-4) which are used to set the upper limit, W3-W7, and the lower limit, TP1-TP10 (wire wrap posts).

Two regions of UNIBUS addresses may be mapped to main memory. These regions are referred to as the lower and upper window. The lower window expands upward from $\emptyset K$; the upper window expands downward from 124 K. See Figure 6-7.

The lower limit jumpers are used to select the first address that will not be mapped to main memory. The lower limit allows the UNIBUS space that will be mapped (via the lower window) to main memory to be expanded upward from UNIBUS address 000 000 up to 760 000 in 4K word segments. If the lower limit jumpers are set to 000 000, the lower window does not exist.

The upper limit jumpers are used to select the first address that will be mapped to main memory via the upper window. The upper limit allows the UNIBUS space that will be mapped to main memory to be expanded downward from UNIBUS address 760 0008 in 4K word segments. If the upper window jumpers are set to 760 0008, the upper window does not exist.

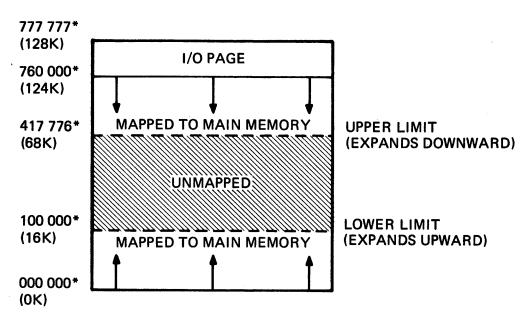

Figure 6-7 shows how the addressing limits affect UNIBUS space. When the upper and lower limits are set to address 000 000, (0K) or 760 000, (124K) or if the limits overlap (e.g., lower limit = 600 000, (96K), upper limit = 400 000, (64K)) all of the UNIBUS space, with the exception of the I/O page, will be passed to main memory.

The UNIBUS I/O page is always mapped to the main memory I/O page, regardless of the contents of the 32nd map register or the state of the UNIBUS map.

The signal K1-4 FORCE JUMPERS H, when asserted, causes a default of the addressing limits to the all jumpers out condition. This signal is used for diagnostic and maintenance purposes to force the UNIBUS map addressing limits to a known condition. The FORCE JUMPERS Bit is set under program control. For proper operation of this bit, any conflicting UNIBUS devices or memory may need to be removed.

6.3 BOOT LOGIC

The KT24 UNIBUS Map Option contains boot logic that is compatible with the M9312 bootstrap. The bulk of this logic is located on K1-4, K1-9 and K1-10 of the print set. This logic consists of four interchangable device boot ROMs, the PDP-11/24 diagnostic ROM, and the necessary logic, switches, and jumpers to implement the bootstrap programs. Section 2.8.3 of this manual explains the function of the switches and jumpers. The following paragraphs explain the operation of the boot logic.

*18-BIT UNIBUS ADDRESSES

TK-5346

Figure 6-7 UNIBUS Map Addressing Limits

A boot is enabled by one of the following actions:

- 1. System power-up (jumper selectable on the CPU module).
- 2. By moving the front panel switch to the BOOT position and then back to the CONT position.
- 3. By loading the starting address of the boot program and starting the processor.

When a boot on System Power-up or via the front panel switch is performed the boot starting address is determined by S1 and S3-S10 of switch pack E58.

The boot logic consists of an address decode PLA, a decoder, a delay line, a counter, a shifter, a buffer, and associated logic. This circuitry is used to decode a boot address, assemble a 16-bit word from a 4-bit ROM and assert it on the UNIBUS.

The address decode PLA (E92) decodes the boot addresses and enables one of the four device boot ROMS or the CPU diagnostic ROM via decoder (E88). With S2 of E58 closed (boot logic enabled) K4-4 BOOT READ L is asserted by the address decode PLA. K4-4 BOOT READ L sets the counter (E81) to Ø and is ANDed with K4-3 BUS MSYN H to assert the input of an oscillator made up of a delay line (E31) along with AND gates E57 and E67. T90 H toggles the input to the delay line generating the clock pulses needed to increment the counter (E81) and clock the shifter. As the counter is incremented, two address bits, LSB H and MSB H, are generated. These address bits are used to address 4 contiguous 4-bit words in the enabled ROM. These four words are assembled into one 16-bit word in the shifter (E41 and E50). After the fourth clock pulse to the counter (INC H) the oscillator is stopped and the 16-bit word generated from the ROM is buffered and then asserted on the UNIBUS by the assertion ENB READ DAT L and UBI SSYN H is asserted.

Figure 6-8 shows the timing associated with the generation of a 16-bit word from one of the five ROMs.

When the switches (E58 S1, S3-S10) are to supply the boot starting address, ACC SWITCHES L and BOOT 1 L are asserted by the address decode logic. UNIBUS address 773 024 is the address of switch pack E58. This action causes the switches (E58 S3-S10) to replace BUF ROM <16:09> H, and BOOT ROM 1 supplies BUF ROM <08:01> H to the buffer. This action allows the CPU to read the switches and thereby select the boot function to be performed. In addition, switch S1 will select 165 XXX8 or 173 XXX8, through the control of XOR gates E49. Device boot ROM 1 must be installed for the switch pack to function properly.

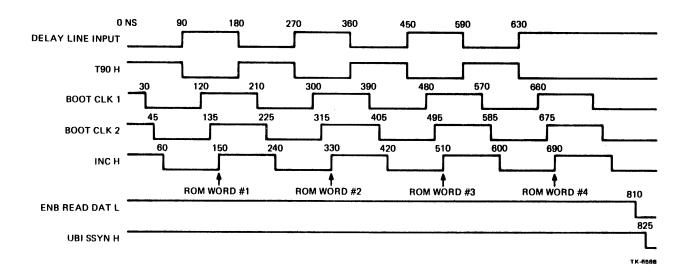

Figure 6-8 Boot Timing

6.4 VOLTAGE MONITOR

The voltage monitor on the KT24 UNIBUS Map Option monitors the voltages supplied to the PDP-11/24 and memory. If one of the supply voltages is out of tolerance, an error condition exists and the power-fail bit in the CPU Error Register is set. Additionally the "DC ON" light located on the PDP-11/24 console will flash at a rate of 5 Hz as long as the out of tolerance condition exists. Table 6-2 lists the supply voltages and their limits.

The voltage monitor (K1-2) uses a comparator network (E15, E23 and E7) to compare the various voltages used in the PDP-11/24 to a fixed reference voltage. If any one of these voltages goes out of tolerance, the output of its respective comparator will go low. When the output of any comparator goes low, the power-fail bit (E48) of CPU Error Register is set, and a 5 Hz oscillator comprised of a timer (E24) and its associated circuitry is enabled causing the "DC ON" light to flash. When the power-fail bit of the CPU register has been set it is cleared by an INIT or by writing to the CPU Error Register. Switches S1, S2 and S4 of E6 are used to isolate the different voltage comparators for maintenance purposes.

6.5 REGISTERS

The KT24 UNIBUS Option contains the UNIBUS map registers, the Last Mapped Address (LMA) register, and the CPU Error register. The following paragraphs describe the registers.

6.5.1 UNIBUS Map Registers

There are 32 mapping registers, each containing a 21-bit mapping offset. Each mapping register is contained in two 16-bit registers; one register contains bits <15:01> (Low Word) and the other register contains bits <21:16> (High Word). Table 6-1 lists the register address. Figure 6-9 shows the bit configuration of the registers.

6.5.2 Last Mapped Address (LMA) Register

The LMA is a two-word register located at addresses 17 777 7348 (Low Word) and 17 777 7368 (High Word) that contains the 22-bit memory (EUB) address of the last mapped address. This register is used for maintenance purposes and also contains the memory control lines, Cl and CØ, and the Force Jumpers bit. Table 6-3 describes the LMA bits. Figure 6-10 shows the LMA configuration.

6.5.3 CPU Error Register

The CPU Error Register is located at address 17 777 766 $_{\rm g}$. This register is read-only; any attempt to write to it will clear the power-fail bit. Table 6-4 describes the CPU Error Register bits and Figure 6-11 shows the register configuration.

Table 6-2 Voltage Limits

Supply Voltage	Limits Lo	ні
+5.1 V	+4.64 V	+5.56 V
+5 B	+4.54 V	+5.66 V
+15 V	+13.35	+16.65

FLOATING POINT PROCESSOR FUNCTIONAL DESCRIPTION

7.1 INTRODUCTION

The KEF11-A Floating-Point Processor (FPP) is a microcode option for use with the PDP-11/24 processor. The KEF11-A is completely software compatible with all FP11 floating point processors. Both single (32-bit) and double (64-bit) precision floating-point capabilities are available together with other features such as floating to integer and integer to floating data conversion.

The FPP microcode resides in two control chips packaged on one 40-pin hybrid DIP. The FPP requires the MMU chip to be present in the system (in addition to the base machine chip) because the MMU chip contains the floating-point accumulators and status registers (Figure 7-1).

7.2 FLOATING-POINT FORMATS

The FPP requires its input data (operands) to be formatted. This formatting allows the FPP to process operands in a meaningful way and produce correct results. There are four different formats for operands input to the FPP: short-integer format (I), long-integer format (L), single-precision floating format (F), and double-precision floating format (D).

Output data from the FPP is also formatted. This output data is in the form of:

- 1. FPP status information and FPP exception information required by the CPU
- Data sent to memory (via the CPU), which must be in I, L, F, or D format.

7.2.1 FPP Integer Formats

There are two integer formats, short (I) and long (L). The short-integer format is 16 bits long and the long-integer format is 32 bits long. Data words (operands) in integer format are represented in 2's complement notation. In both I and L formats, the most significant bit of the data word is the sign bit. Figure 7-2 shows the integers +5 and -5 in both I and L formats.

Figure 7-3 also illustrates the formats in which integers are arranged in memory. Integers will be sent to memory in one of these formats.

7.2.2. FPP Precision Formats

There are two floating-point precision formats, single-precision (F) and double-precision (D). The single-precision format is 32 bits long and the double-precision format is 64 bits long. Figure 7-3 shows that the most significant bit of the double (single-precision) or quad (double-precision) word is the sign of the fraction (and the floating-point number being represented).

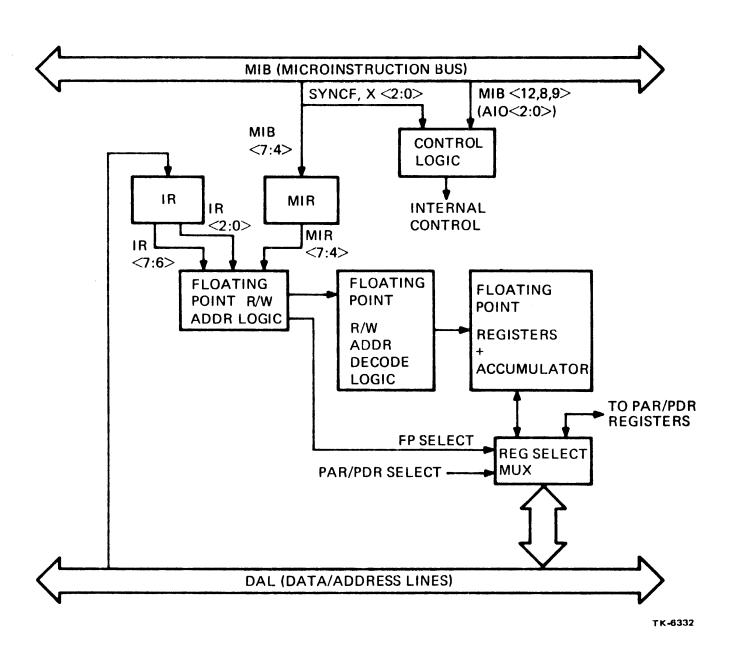

Figure 7-1 Block Diagram of Floating-Point Logic on MMU

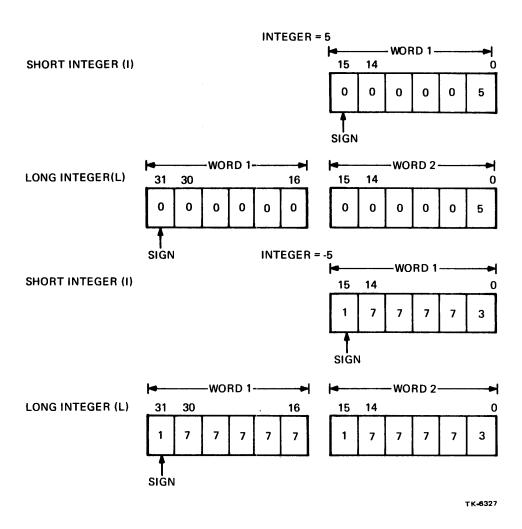

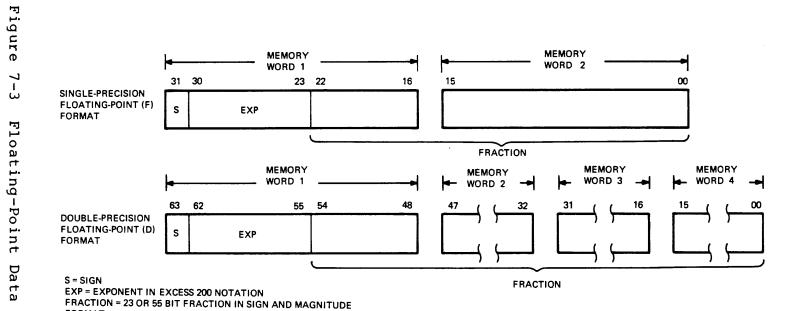

Figure 7-2 Integer Formats

FORMAT.

Formats

TK-6325

The next 8 bits contain the value of the exponent, expressed in excess 200 notation. The remaining bits (23 for single-precision, 55 for double-precision) contain the fraction. The fraction and its associated sign bit are expressed in sign and magnitude notation.

7.2.3 Floating-Point Data Word

Figure 7-4 illustrates the formats in which floating-point numbers are arranged in memory. Floating-point numbers sent to memory must be in one of these formats. Floating-point numbers received by the FPP are arranged as illustrated in Figure 7-5.

The sign bit, exponent bits, and fraction bits in the FPP data word have the same values as the data word in memory. Note, however, that the FPP data word has more bits than its counterpart in memory. This is because the FPP has provisions for generating an overflow bit and a "hidden" bit.

For purposes of discusion, the FPP data word can be thought of as being divided into two major parts:

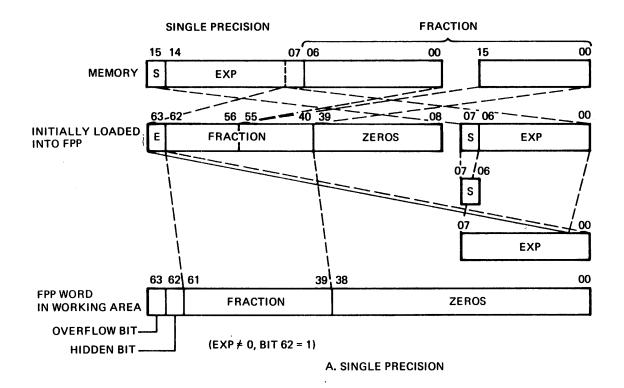

- A fraction, with its associated sign bit, hidden bit, and overflow bit.
- An exponent.

7.2.3.1 Floating-Point Fraction -- The fraction is expressed in sign and magnitude notation. The following simple example illustrates the idea behind sign and magnitude notation.

	2's Complement Notation	Sign and Magnitude Notation
+2	000010	Sign Magnitude
-2	111110	100010 Sign Magnitude

Only a change of sign bit is required to change the sign of a number in sign and magnitude notation. Note that a positive number is the same in both sign-magnitude and two's complement notation.

Unnormalized floating-point fractions have a range from approximately \emptyset through 2 as shown in Figure 7-6. The FPP, however, normalizes all unnormalized fractions. That is, the fractions are adjusted such that there is a \emptyset to the left of the binary point (bit 63) and a 1 to the right of the binary point (bit 62). Thus, normalized fractions range in magnitude from $\emptyset.1000...$ to $\emptyset.1111$ or from 1/2 to approximately 1.

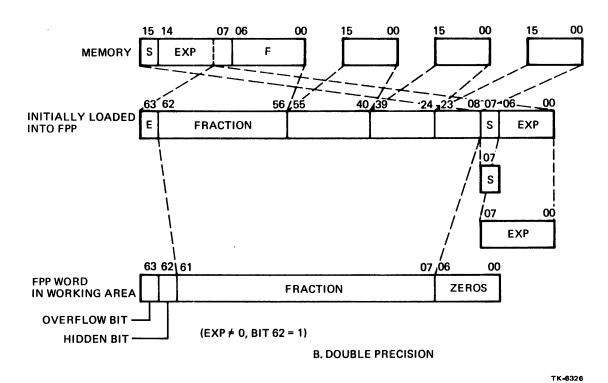

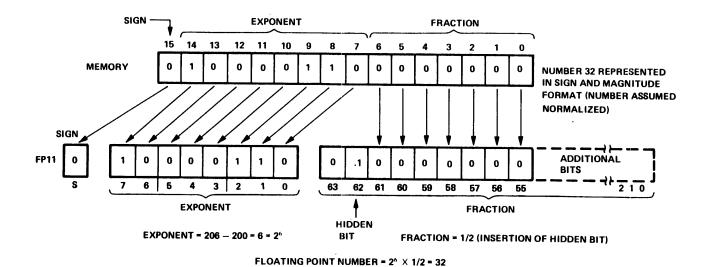

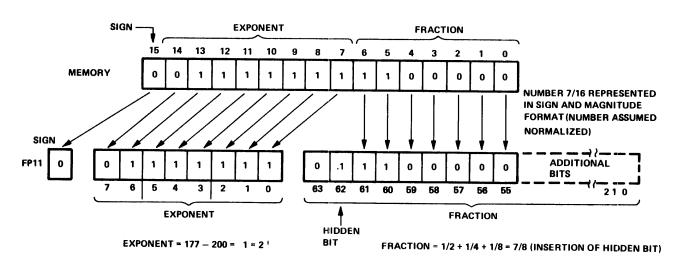

Figure 7-4 Floating-Point Data Words

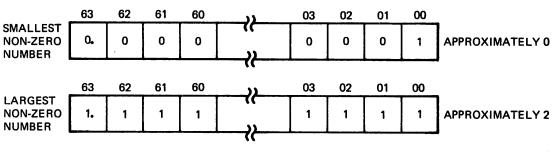

FLOATING POINT NUMBER = 2 $^{\circ}$ \times 7/8 = 7/16

TK-833

Figure 7-5 Interpretation of Floating-Point Numbers

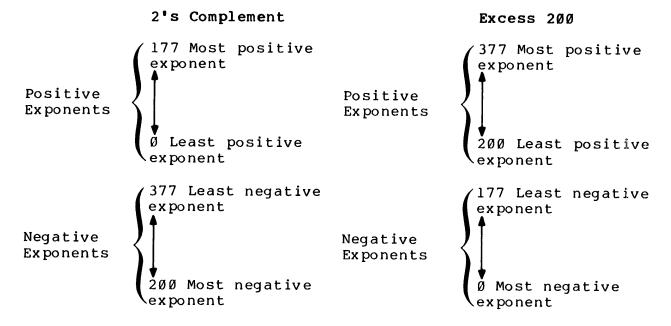

TK-6331

Figure 7-6 Unnormalized Floating-Point Fraction

Bit 62 is called the hidden bit. Recall that since fractions are normalized by the FPP, the bit immediately to the right of the binary point (bit 62) is always a 1. This bit is dropped when a fraction is sent to memory and appended when a fraction is received from memory. This procedure allows one extra bit of significance in floating- point fraction representation.

The fraction overflow bit (bit 63) is set during certain arithmetic operations. For example, during addition, certain sums will produce an overflow such as $\emptyset.1000...+\emptyset.100...$ which yields 1.000... This result must be normalized, so that FPP right-shifts the fraction one place and increases the exponent by one.

7.2.3.2 Floating-Point Exponent -- The 8-bit floating-point exponent is expressed in excess 200 notation. The chart below illustrates the relationship between exponents in 2's complement notation and exponents in excess 200 notation.

Note that an exponent in excess 200 notation is obtained by simply adding 200 to the exponent in 2's complement notation. Thus, 8-bit exponents in excess 200 notation range from 0 to 377 (or from -200 to +177). A number with an exponent of -200 is treated by the FPP as 0.

For example, the number $\emptyset.1_2$ is actually $\emptyset.1$ X 2^{\emptyset} , and the exponent is represented as $10^2\,000\,000$ because 200_8 represents an exponent of zero.

7.2.4 Processing of Floating-Point Exceptions
Location 244 is the interrupt vector used to handle all floating-point interrupts. A total of six possible interrupts can occur. These possible interrupt exceptions are encoded in the FPP exception code (FEC) register. The interrupt exception codes

represent an offset into a dispatch table, which routes the program to the right error handling routine. The dispatch table is a function of the software. The FEC for each exception is briefly described in Table 7-1.

Refer to the PDP-11 Processor Handbook for further details concerning FPP exceptions.

In addition to the FEC register, the CPU contains a 16-bit Floating Exception Address (FEA) register, which stores the address of the last floating-point instruction that caused a floating-point exception.

- 7.3 FLOATING-POINT PROCESSOR STATUS REGISTER (FPS)
 The Floating Point Status Register provides mode and interrupt control for the FPP as well as conditions codes resulting from the execution of the previous floating-point instruction. Figure 7-7 illustrates the bits of the FPS and Table 7-2 provides a description of each bit in the register.
- 7.4 FLOATING-POINT INSTRUCTIONS
 Section 7.4 provides a description of the FPP Floating-Point instructions and instruction formats. A description of the Floating-point accumulators is also provided.
- 7.4.1 Floating-Point Accumulators
 The MMU chip contains the six general-purpose accumulators (AC \emptyset -AC5) used by the FPP. These accumulators are 64-bit read/write scratchpad memories with nondestructive readout.

Each accumulator is interpreted as being either 32 or 64 bits long, depending on the instruction and the FPP status. If an accumulator is interpreted as being 64 bits long, 64 bits of data occupy the entire accumulator. If an accumulator is interpreted as being 32 bits long, 32 bits of data occupy only the left-most 32 bits of an accumulator as shown in Figure 7-8.

The floating-point accumulators are used in numeric calculations and interaccumulator data transfers. AC \emptyset -AC3 are used for all data transfers between the FPP and the CPU or memory.

7.4.2 Instruction Formats

An FPP instruction must be in one of five formats. These formats are summarized in Figure 7-9.

The 2-bit AC field (bits 6 and 7) allows selection of scratchpad accumulators Ø through 3 only.

If address mode \emptyset is specified with formats Fl or F2, bits 2- \emptyset are used to select a floating-point accumulator. Only accumulators \emptyset -5 can be specified in mode \emptyset . If 6 or 7 is specified in bits 2- \emptyset in mode \emptyset , the FPll traps if floating-point interrupts are enabled (FID = \emptyset). The FEC will indicate an illegal op code error (exception code \emptyset 2).

Table 7-1 FPP Exception Codes

FP11-A Exception	
Code	Definition
Ø 2	Floating Op Code Error - The FPP causes an interrupt for an erroneous op code.
Ø 4	Floating Divide by Zero - Division by zero causes an interrupt if FID bit in the FPS register is not set.
Ø 6	Floating (or Double) Integer Conversion Error
10	Floating Overflow
12	Floating Underflow
14	Floating Undefined Variable

NOTE

The traps for exception codes $\emptyset 6$, $1\emptyset$, 12, and 14, can be enabled in the FPP program status register. All traps are disabled if FID bit is set.

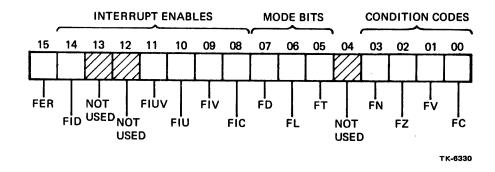

Figure 7-7 Floating-Point Processor Status Register

Table 7-2 Floating-Point Processor Status Register

Bit		Description
<15>	FER	This bit indicates an error condition of the FPP.
<14>	FID	Floating Interrupt Disable - All interrupts by the FPP are disabled when this bit is on. Primarily for maintenance use. Normally clear.
<13>		Not Used
<12>		Not Used
<11>	FIUV	Floating Interrupt on Undefined Variable if -Ø is obtained from memory, an interrupt occurs. If the FIUV bit is not set -Ø can be loaded and stored; however, any arithmetic operation treats it as if it were a positive Ø.
<10>	FIU	Floating Interrupt on Underflow - When this bit is set, an underflow condition causes a floating underflow interrupt. The result of the operation causing the interrupt is correct except for the exponent, which is off by 400. If the FIU is not set and underflow occurs, the result is set to zero.
<09>	FIV	Floating Interrupt on Overflow - When this bit is set, floating overflow causes an interrupt. The result of the operation causing the interrupt is correct except for the exponent, which is off by 400.
<08>	FIC	Floating Interrupt on Integer Conversion Error - When this bit is set and the store convert floating-to-integer instruction causes FC to be set (indicating a conversion error), an interrupt occurs. When an interrupt occurs, the destination register is cleared and the source register is untouched. When FIC is reset, the result of the operation is the same; however, no interrupt occurs.

Table 7-2 Floating-Point Processor Status Register (Cont)

Bit		Description
<07>	FD	Double-Precision Mode Bit - This bit, when set, specifies double-precision (64-bit) format and, when reset, specifies single-precision (32-bit) format.
<06>	FL	Long-Precision Integer Mode Bit - This bit is employed during conversion between integer and floating-point format. If set, double-precision 2's complement integer format of 32 bits is specified; if reset, single-precision 2's complement integer format of 16 bits is specified.
<05>	FT	Truncate Bit - This bit, when set, causes the result of any floating-point operation to be truncated rather than rounded.
<04>	Not Used	
<03:00>	FN, FZ, FV, and FC	These bits are the four floating-point condition codes, which can be loaded in the CPU's N, Z, V, and C condition codes, respectively. This is accomplished by the copy floating condition codes (CFCC) instruction.

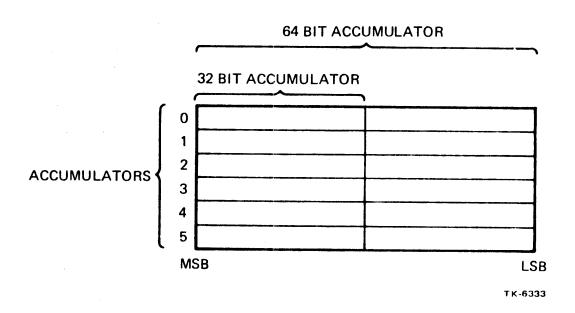

Figure 7-8 Floating-Point Accumulators

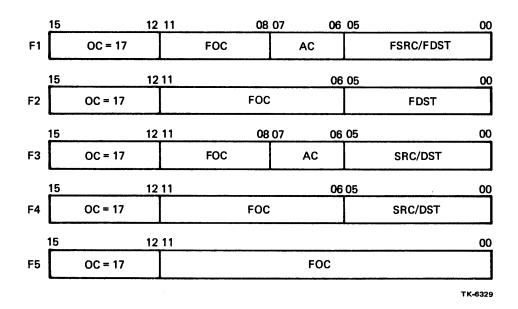

Figure 7-9 Instruction Formats

The fields of the various instruction formats (as summarized in Table 7-3) are interpreted as follows.

Mnemonic	Description
OC	Operation Code - All floating-point instructions are designated by a 4-bit op code of 178.
FOC	Floating Operating Code - The number of bits in this field varies with the format; the code is used to specify the actual floating-point operation.
SRC	Source - A 6-bit source field identical to that in the PDP-11 instruction.
DST	Destination - A 6-bit destination field identical to that in a PDP-11 instruction.
FSRC	Floating Source - A 6-bit field used only in format Fl. It is identical to SRC, except in mode \emptyset when it references a floating-point accumulator instead of a CPU general register.
FDST	Floating Destination - A 6-bit field used in formats Fl and F2. It is identical to DST, except in mode \emptyset when it references a floating-point accumulator instead of a CPU general register.
FAC	Floating Accumulator - A 2-bit field used in formats Fl and F3 to specify FPll scratchpad accumulators \emptyset -3.

7.5 FLOATING-POINT INSTRUCTIONS

7.5.1 Arithmetic Instructions

The arithmetic instructions (add, subtract, multiply, divide) require one operand in a source (a floating-point accumulator in mode \emptyset , a memory location otherwise) and one operand in a destination accumulator. The instruction is executed by the FPP and the result is stored in the destination accumulator.

The Compare instruction also requires one operand in a source and one operand in a destination accumulator. However, the two operands remmain in their respective locations after the instruction is executed by the FPP, and there is no transfer of the result.

7.5.2 Floating-Modulo Instruction

The Floating-Modulo (MOD) instruction causes the FPP to multiply two floating-point operands, separate the product into integer and fractional parts, and store one or both parts as floating-point numbers. The whole-number portion goes into an odd-numbered accumulator and the fraction goes into an even-numbered accumulator.

The whole-number portion of the number, when expressed as a floating-point number, contains an exponent greater than 201 in excess 200 notation, which means the the whole number has a decimal value of some number greater than one and less than UPLIM, where UPLIM is the greatest possible number that can be represented by the FPP.

The fractional portion of the number, when expressed as a floating-point number, contains an exponent less than or equal to 201 in excess 200 notation. This means that the fraction has a value less than one and greater than LOLIM, where LOLIM is the smallest possible number that can be represented by the FPP.

7.5.3 Load Instruction

The Load instruction causes the FPP to take an operand from a source and copy it into an accumulator. In mode \emptyset the source is a floating-point accumulator, otherwise, the source is a memory location.

7.5.4 Store Instruction

The Store instruction causes the FPP to take an operand from a source accumulator and transfer it to a destination. This destination is a floating-point accumulator in mode \emptyset and a memory location otherwise.

7.5.5 Load Convert (Double-to-Floating, Floating-to-Double) Instructions

The Load Convert Double-to-Floating (LDCDF) instruction causes the FPP to assume that the source specifies a double-precision floating-point number. The FPP then converts that number to

single-precision, and places this result in the destination floating accumulator. If the floating-truncate (FT) status bit is set, the number is truncated. If the FT bit is not set, the number is rounded.

The Load Convert Floating-to-Double (LDCFD) instruction causes the FPP to assume that the source specifies a single-precision number. The FPP then converts that number to double-precision by appending 32 zeros to the single-precision word, and places this result in the destination accumulator.

Note that for both Load Convert instructions, the number to be converted is originally in the source (a floating-point accumulator in mode \emptyset , a memory location otherwise) and is transferred to the destination accumulator after conversion.

7.5.6 Store Convert (Double-to-Floating, Floating-to-Double) Instructions

The Store Convert Double-to-Floating (STCDF) instruction causes the FPP to convert a double-precision number located in the source accumulator to a single-precision number. The FPP then transfers this result to the specified destination. If the floating-truncate (FT) bit is set, the floating-point number is truncated. If the FT bit is not set, the number is rounded. If the MSB (bit 31) of the double-precision segment of the word is a 1, 1 is added to the single-precision segment of the word, depending on the prior conditions set up by the FD bit in the FPS register; otherwise, the single-precison segment remains unchanged.

The Store Convert Floating-to-Double (STCFD) instruction causes the FPP to convert a single-precision number located in the source accumulator to a double-precision number. The FPP then transfers this result to the specified destination. The single-to-double precision is obtained by appending zeros equivalent to the double-precision segment of the word (Figure 7-10).

Note that for both Store Convert instructions, the number to be converted is originally in the source accumulator and is tranferred to the destination (a floating-point accumulator in mode Ø, a memory location otherwise) after conversion.

7.5.7 Clear Instruction

The Clear instruction causes the FPP to clear a floating-point destination by setting all its bits to \emptyset .

7.5.8 Test Instruction

The Test instruction causes the FPP to test the sign and exponent of floating-point number and update the FPP status accordingly. The number tested is obtained from the destination (a floating-point accumulator in mode Ø, a memory location otherwise). The FC and FV bits are cleared. The FN bit is set only if the destination is negative. The FZ bit is set only if the exponent of the destination is zero. If the FIUV status bit

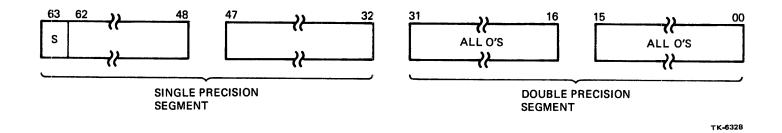

Figure 7-10 Single-to-Double Precision Appending

is set, a trap occurs (after the test instruction is executed) if a minus zero is encountered, indicating an undefined variable.

- 7.5.9 Absolute Instruction
 The Absolute instruction causes the FPP to take the absolute value of a floating-point number by forcing its sign bit to 0. If mode 0 is specified, the sign of the number in the floating-point destination accumulator is forced to 0. The exponent of the number is tested, and if it is 0, zeros are written into the accumulator. If the exponent is nonzero, the accumulator is unaffected.
- 7.5.10 Negate Instruction
 The Negate instruction causes the FPP to complement the sign of the operand and store the result in the same location.
- 7.5.11 Load Exponent Instruction
 The Load Exponent instruction causes the FPP to load an exponent
 from the source (a floating-point accumulator in mode Ø, a memory
 location otherwise) into the exponent field of the destination
 floating accumulator. In order to do this, the 16-bit, 2's
 complement exponent from the source must be converted to an 8-bit
 number in excess 200 notation. This process is described further
 below.

Assume that the 16-bit, 2's complement exponent is coming from memory. The possible legal range of 16-bit numbers in memory is from 000 0008 to 177 7778. On the other hand, the possible legal range of exponents in the FPP falls into two classes.

- 1. Positive exponents (\emptyset_8 through 177₈) When 200₈ is added to any of these numbers, the sum stays within the legal 8-bit exponent field (i.e., from 200₈ through 377₈).
- 2. Negative exponents (177 6018 through 177 7778) When 2008 is added to any of these numbers, the sum stays within the legal 8-bit exponent field (i.e., from 18 through 1778).
- 7.5.12 Load Convert Integer-to-Floating Instruction
 The Load Convert Integer instruction takes a 2's complement integer from memory and converts it to a floating-point number in sign and magnitude format. If short-integer mode is specified, the number from memory is 16 bits and is converted to a 24-bit fraction (single-precision) or a 56-bit fraction (double-precision), depending on whether floating or double mode is specified. In each case the appropriate exponent is assigned.

When loading a long integer in the single precision floating mode, if the long integer contains more than 24 significant digits, then less significant digits will be truncated with some loss of accuracy.

7.5.13 Store Exponent Instruction The Store Exponent (STEXP) instruction causes the CPU to access a floating-point number in the FPP, extract the 8-bit exponent field from this number, and subtract a constant of 200_8 (since the exponent is expressed in excess 200_8 notation). The exponent is then stored in the destination as a 16-bit, 2's complement,

The legal range of exponents if from \emptyset_8 to 3778, expressed in excess 200 notation. This means that the number stored ranges from -200_8 to 1778 after the constant of 200 has been subtracted.

7.5.14 Store Convert Floating-to-Integer Instruction
The Store Convert Floating-to-Integer instruction causes the FPP
to take a floating-point number and convert it to an integer for
transfer to a destination.

The four classes of this instruction are as follows:

right-justified number.

- STCFI Convert single-precision, 24-bit fraction to a 16-bit integer (short-integer mode).
- 2. STCFL Convert single-precision, 24-bit fraction to a 32-bit integer (long-integer mode).
- 3. STCDI Convert double-precision, 56-bit fraction to a 16-bit integer (short-integer mode).
- 4. STCDL Convert double-precision, 56-bit fraction to a 32-bit integer (long-integer mode).

The (normalized) floating-point number to be converted is transferred to the FPP. The FPP works with the sign bit and one of the following.

- 1. The 15 MSBs of the fraction for Floating-to-Integer and Double-to-Floating conversion.
- 2. The 31 MSBs of the fraction for Double-to-Long conversion.
- The entire fraction for Floating-to-Long converions.

The FPP subtracts 201_8 from the exponent to determine if the floating-point number is a fraction. If the result of the subtraction is negative, the exponent is less than 201_8 , and the absolute value of the floating-point number is less than 1. When converted to an integer, the value of this number is 0; a conversion error occurs, the FZ bit is set, and 0s are sent to the destination. If the result of the subtraction is positive (or zero), it indicates that the exponent is greater than (or equal to) 201_8 , and the floating-point number can be converted to a nonzero integer.

7.5.15 Load FPP's Program Status

This instruction causes the FPP to transfer 16 bits from the location specified by the source to the floating-point status (FPS) register. These 16 bits contain status information for use by the FPP in order to enable and disable interrupts, set and clear mode bits, and set condition codes.

7.5.16 Store FPP's Program Status

This instruction causes the FPP to transfer the 16 bits of the FPS register to the specified destination.

7.5.17 Store FPP's Status

The Store FPll's Status (STST) instruction causes the FPP to read the contents of the floating exception code (FEC) and floating exception address (FEA) registers when a floating-point exception (error) occurs.

If mode Ø addressing is enabled, only the FEC is sent to the destination accumulator. If mode Ø addressing is not enabled, the FEC is stored in memory followed by the FEA. In memory, the FEA data occupies all 16 bits of its memory location, while the FEC data occupies only the lower 4 bits of its location.

When an error occurs and the interrupt trap in the CPU is enabled, the CPU traps to interrupt vector $244_{\rm e}$. The program then issues the STST instruction to determine the type of error.

NOTE

The STST instruction should be used only after an error has occurred, since in all other cases the instruction contains irrelevant data or contains the conditions that occurred after the last error.

7.5.18 Copy Floating Condition Codes

The Copy Floating Condition Codes (CFCC) instruction causes the FPP to copy the four floating condition codes (FN, FZ, FV, FC) into the CPU condition codes (N, Z, V, C).

7.5.19 Set Floating Mode

The Set Floating Mode (SETF) instruction causes the FPP to clear the FD bit (bit <0.7> of the FPS register) and indicate single-precision operation.

7.5.20 Set Double Mode

The Set Double Mode (SETD) instruction causes the FPP to set the FD bit (bit <0.7> of the FPS register) and indicate double-precision operation.

7.5.21 Set Integer Mode

The Set Integer Mode (SETI) instruction causes the FPP to clear the FL bit (bit <06> of the FPS) and indicate that short-integer mode (16 bits) is specified.

7.5.22 Set Long-Integer Mode

The Set Long-Integer Mode (SETL) instruction causes the FPP to set the FL bit (bit <06> of the FPS) and indicate that long-integer mode (32 bits) is specified.

7.6 FLOATING-POINT INSTRUCTION EXECUTION

Floating-point macroinstructions are directly loaded into the PLA input register (PIR) of the base machine control chip via the DAL. The base machine control chip decodes the floating-point instruction and issues an unconditional branch microinstruction to the floating-point chip via the MIB. It should be noted that every control chip latches the microinstruction into its microinstruction register to determine if it is the selected chip. The floating-point chip decodes the microinstruction and branches to the location in its control store which decodes the specified floating-point routine. The floating-point chip also asserts its chip select line (K13 CSEL 2 L) indicating that it has recognized the jump microinstruction. After address in floating-point routine has been completed the floating point chip issues an unconditional jump back to the base machine control chip. If the floating-point chip does not assert K13 CSEL 2 L or if there is no floating-point chip present in the system, K7 CTL ERR H will be asserted at PBT2. K7 CHIP RESET H will also be asserted at the end of PBT2 to initialize the LSI chips in the K7 CHIP RESET H when asserted forces control of the processor back to the base machine control chip and the service microstate to be entered. K7 CTL ERR H being asserted cuases a trap through the vector at 10_8 . This trap indicates an attempt to execute a reserved instruction, in this case, the missing floating-point instruction. K13 CHIP RESET H will be cleared on the following MCLK after service information has been loaded into the system.

8.1 INTRODUCTION

The Commercial Instruction Set Processor (CISP) is a microcode option (KEF11-B) for use with the PDP-11/24 processor. The KEF11-B is completely software compatible with the KE44-A CISP which is used with the PDP-11/44 processor. The KEF11-B option significantly extends the capability of the PDP-11/24 in the area of commercial data processing.

The commercial instruction set (CIS) is a series of instructions for manipulating byte strings which provide improved COBOL performance, text editing and word processing capabilities. instructions for character handling and decimal arithmetic operations. Each of these instructions have two forms, CIS register form instructions load register and in-line. descriptors into the general registers and then perform the instruction. CIS in-line form instructions call the descriptors through descriptor address pointers. The CIS also includes load two descriptors and load three descriptors instructions. instructions augment the register form of the instructions by making it easy to load descriptors into registers. Descriptors are used to identify character strings, they consist of the starting address of the string and the length of the string. complete description of the function of the PDP-11/24 Commercial Instruction Set and its instructions is provided in the PDP-11 Processor Handbook.

The CISP microcode resides in six control chips packaged on one 40 pin double width hybrid package. The CISP requires only the base machine chip to be installed in the system to use the Commercial Instruction Set. The CISP option may be added or removed from the system simply by installing or removing the CISP hybrid.

The microcode for the various CIS instructions is divided among the six CISP chips. Table 8-1 lists the location of the microcode for the CIS instructions. All CIS instructions are dispatched through the first CISP chip. All in line descriptor calculations are also done in this chip before dispatch.

8.2 CHARACTER DATA TYPES

There are three different character data types. The "character" is a single byte, and is an abbreviated string of length 1. The "character string" is a contiguous group of bytes in memory. The third is a "character set."

The character is an 8-bit byte:

	7	Ø
Α	char

The character is used as an operand by CIS instructions. When it appears in a general register, the character is in the low order half; the high order half of the register must be zero. When it appears in the instruction stream, the character is in the low order half of a word; the high order half of the word must be zero. If the high order half of a word which contains a character is non-zero, the effect of the instruction which uses it will be unpredictable.

A character string is a contiguous sequence of bytes in memory that begins and ends on a byte boundary. It is addressed by its most significant character (lowest address). The highest address is the least significant character. It is specified by a two word descriptor with the attributes of length and lowest address. The length is an unsigned binary integer which represents the number of characters in the string and may range from \emptyset to 65,535. A character string with zero length is said to be vacant: its address is ignored. A character string with non-zero length is said to be occupied.

The character string descriptor is used as an operand by CIS instructions. It appears in two consecutive general registers, or in two consecutive words in memory pointed to by a word in the instruction stream. The following figure shows the descriptor for a character string of length "n" starting at address "A" in memory:

	15	Ø
Rx	n	
Rx + 1	A	

The following shows the character string in memory:

	7		Ø
A		MOST SIG CHAR	
			
A + 1			
		•	
		•	
		•	
A + n	- 1	LEAST SIG CHAR	

A "character set" is a subset of the 256 possible characters that can be encoded in a byte. It is specified by a descriptor which consists of the address of a 256-byte table and an 8-bit mask. The address is of the zeroeth byte in the table. Each byte in the

table specifies up to eight orthogonal character subsets of which the corresponding character is a member. The mask selects which combinations of these orthogonal subsets comprise the entire character set. In effect, each bit in the mask corresponds to one of eight orthogonal subsets that may be encoded by the table. The mask specifies the union of the selected subsets into the character set. Typical sets would be: upper case, lower case, non-zero digits, end of line, etc.

8.3 DECIMAL STRING DATA TYPES

Two classes of decimal string data types - numeric strings and packed strings - are defined. Both have similar arithmetic and operational properties; they primarily differ in the representation of signs and the placement of digits in memory.

The numeric string data types are signed zoned, unsigned zoned, trailing overpunch, leading overpunched, trailing separate and leading separate. The packed string data types are signed packed and unsigned packed. Instructions which operate on numeric strings permit each numeric string operand to be separately specified; similarly, packed string instructions permit each packed string operand to be separately specified. Thus, within each of the two classes of decimal strings, the operands of an instruction may be of any data type within the appropriate class.

Decimal strings exist in memory as contiguous bytes which begin and end on a byte boundary. They represent numbers consisting of Ø to 31,0 digits, in either sign-magnitude or absolute-value form. Sign-magnitude strings (SIGNED) may be positive or negative; absolute-value strings (UNSIGNED) respresent the absolute value of the magnitude. Decimal numbers are whole integer values with an implied decimal radix point immediately beyond the least significant digit; they may be conceptually extended with zero digits beyond the most significant digit.

8.4 CIS INSTRUCTION EXECUTION

CIS macroinstructions are directly loaded into the PLA input register (PIR) of the base machine control chip via the DAL. The base machine control chip decodes the instruction and issues an unconditional branch microinstruction to the initial CIS chip, via the MIB. The CIS chip decodes the microinstruction and branches to the location in its control store which contains the CIS routine. It should be noted that every control chip latches the microinstruction into its microinstruction register to determine if it is the selected chip. The CIS chip decodes the microinstruction and branches to the location in its control store which contains the CIS routine.

The CIS chip also asserts its chip select line (K13 CSEL 1 L) indicating that it has recognized that it is the destination of the unconditional jump microinstruction. Further decoding of the macroinstruction is all done in the initial CIS chip to determine where the microroutine specified by the macroinstruction resides. If the microroutine resides in the initial CIS chip the routine is

executed and upon completion an unconditional branch to the base machine chip is performed. However, if the microroutine resides in one of the other five CIS chips, the initial CIS chip issues an unconditional branch to the CIS chip which contains the routine. The initial CIS chip will now clear its chip select line and the CIS chip which contains the necessary routine will assert its chip select line and execute the routine. When one of the other five CIS chips recognize the jump microinstruction, it will assert K13 CSEL l L. Upon completion of the CIS routine an unconditional branch microinstruction to the base machine chip is issued.

If the base machine attempts an unconditional microjump to the first CIS chip, and the chip is not present in the system or does not respond, the absence of K13 CSEL1 L or K13 CSEL2 L will cause CTL ERR H to be asserted at PBT2. CHIP RESET H will also be asserted at PBT2 to initialize the other LSI chips in the system. This will cause a re-selection of the base machine control chip, just as though an unconditional micro-jump was directed at it. K7 CHIP RESET H will be cleared on the following MCLK after service information has been loaded into the base machine chip. The base machine then enters the service microstate and K7 CTL ERR H will cause a trap through the vector at 108 to tell the user that the CIS processor is not present or is not functioning properly.

The same process will occur if the first CIS chip fails in its attempt to microjump to another CIS chip. This informs the user that the specific CIS instruction cannot be executed.

This chapter describes the basic troubleshooting procedures and diagnostics used with the PDP-11/24.

9.1 TROUBLESHOOTING PROCEDURES

The tests contained in this section are used to diagnose basic malfunctions of the PDP-11/24. These tests are not to replace MAINdec diagnostics but are to be used in cases when the PDP-11/24 is not functioning well enough to run diagnostics. If the machine is functioning well enough to run diagnostics, refer to Section 9.2 of this manual.

When performing the following tests each test is to be performed in sequence. When a fault is enountered a detailed analysis and repair of the fault should be done before proceeding to the next test. Note that some of the tests require the next test to be performed when a failure occurs, thereby further isolating the cause of the failure.

Before starting the test procedure, the PDP-11/24 must be set to the following conditions:

- Turn the CPU keyswitch to the DC OFF position.
- 2. Turn the console terminal ON.

TEST 1:

- 1. Place the console terminal in the LOCAL mode.
- 2. Check to see that the console terminal is operating properly.

This test is necessary and is not to be skipped. The PDP-11/24 does not have a "lights and switches console"; the ASCII console, therefore, must be operational to have control over and visibility into the PDP-11/24 processor. If the console is operating properly, proceed to Test 2. If not, repair the console and then proceed to Test 2.

TEST 2:

- 1. Place the processor HALT/CONT/BOOT switch in the HALT position.
- Turn the processor keyswitch to the LOCAL position.
- 3. Check the processor fans to see if they are spinning.

If the fans are spinning, proceed to Test 3. If the fans are not spinning, perform the following steps. These steps assume the presence of a DEC power controller (874 or equivalent).

- 1. For all PDP-11/24 variations check to be certain there is AC power at the CPU box. The following steps will verify this.
 - a. Check the cabinet AC power cord, to be sure it is securely plugged into its AC receptacle.
 - b. Check the neon lights on the power controller. They will be lit if AC is present at its input.
 - c. Check the circuit breaker on the power controller, it should be in the ON (1) position.
 - d. Check the CPU power cord, it should be plugged into an unswitched outlet on the power controller. If necessary, plug a known good load (e.g., a lamp) into an outlet on the power control.
 - e. If there is AC power at the CPU, proceed to Step 2 for the BAll-L (5 1/4") mounting box or Step 3 for the BAll-A (10 1/2") mounting box.
- 2. BAll-L (5 1/4") mounting box power check

Check the CPU circuit breaker. It should be in the ON (1) position. The circuit breaker is reached by sliding the CPU a few inches out of its wraparound (Figure 2-5). If the circuit breaker is ON the problem may be:

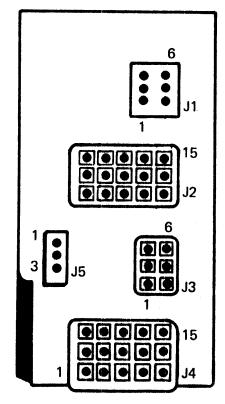

- a. A defective H777 power supply
- b. A blown fuse in the fuse holder next to the CPU circuit breaker
- c. Defective cabling between the CPU front panel and the power supply
- d. A defective front panel module

To diagnose a problem in the front panel and its associated cabling, short pins 1 and 3 of J5 (Figure 9-1) at the back of the mounting box. If the CPU powers up, the problem is with the front panel or its cabling.

3. BAll-A (10 1/2") mounting box power check

Check the CPU circuit breaker located on the back panel of the mounting box (Figure 9-2). It should be in the ON (1) position. If the circuit breaker is already on the problem may be:

a. A defective H7140 power supply

H777 POWER DISTRIBUTION PANEL

TK-6647

Figure 9-1 BAll-L Distribution Panel

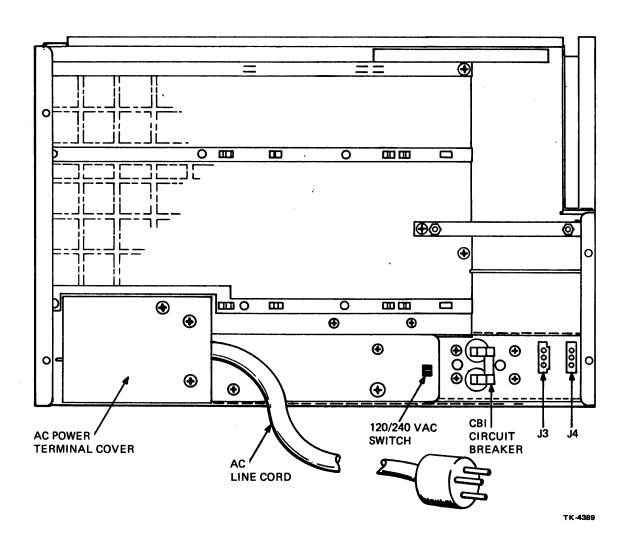

Figure 9-2 BAll-A Backpanel Components

- b. Defective cabling between the CPU front panel and the power supply
- c. A defective front panel module

To diagnose a problem in the front panel and its cabling, short pins 1 and 3 of J3 or J4 at the back of the CPU box. If the CPU powers up, the problem is with the front panel module or its cabling.

TEST 3:

The CPU is now operating minimally, at least to the point that its cooling fans are working. Now inspect the front panel LED labelled DC ON and proceed as indicated in the following steps:

- 1. DC ON is lit steadily proceed to Test 4
- 2. DC ON is not lit indicates that +5 Vdc is not present at the CPU. The most likely cause is a defective power supply.
- 3. DC ON is blinking this condition can exist when the UNIBUS Map Option module (M7134) is present in the system and indicates that +5 Vdc is present but one of the CPU voltages, including +5V, is out of tolerance or E6, S3 on the M7134 module is improperly configured. The out of tolerance voltage can be isolated by reconfiguring S1-S4 of switch pack E6. Section 2.8.3.4 of this manual explains the function of these switches.

TEST 4:

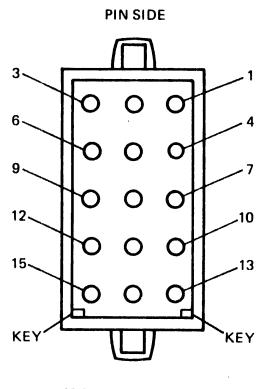

The CPU power is now assumed to be okay.

- 1. If the M7134 UNIBUS Map Option module is present in the system, the voltages are checked by its voltage monitoring circuitry.
- 2. If the M7134 module is not present in the system, the voltages can be checked with a voltmeter or oscilloscope. The voltages can be checked at the backplane power connectors. Figure 9-3 shows the connector, and Table 9-1 gives the signal for each pin.

After verifying the CPU voltages proceed to Test 5.

TEST 5:

Check the condition of the front panel and module LEDs. They should be as follows:

15 PIN CONNECTOR

TK-6648

Figure 9-3 Backplane Power Connector Pin Designations

Table 9-1 PDP-11/24 Backplane Power Connectors

Pin	Signal	
	P2	P4
1	+5 V	+5 V
2	Not Used	Not Used
3	+15 V	+15 V
4	+5 V	+5 V
4 5	Not Used	Not Used
6	Not Used	+12/15 B
7	Not Used	Not Used
	GND	GND
8 9	GND	GND
10	Not Used	Not Used
11	Not Used	Not Used
12	+5 B	Not Used
13	Not Used	Not Used
14	-15 V	-15 V
15	Not Used	-12/15 B

LED CONDITION

Front Panel:

RUN OUT DC ON ON BATT *
PROC OUT

CPU Module:

CLK ON 1 *

Memory Modules:

GREEN ON RED OFF

If all the LEDs are correctly lit, proceed to Test 6. If the LEDs are not correctly lit, refer to Table 9-2.

TEST 6:

The terminal should now be displaying:

ØØØØØØ @

If the terminal output is correct, proceed to Test 7. If the terminal output is not correct perform the following procedures to help isolate the problem.

- If the terminal printed text but the text is garbled, the problem may be the baud rate, stop bits, or parity settings. Check to be sure the terminal and CPU are set up properly.
- 2. If the terminal printed nothing the problem could be:
 - a. The terminal and CPU set-up mentioned in Step 1.
 - b. The connection between the terminal and the CPU. Check to see that the terminal is connected to the SLU connector assembly and that the SLU connector assembly is connected to the CPU.
 - c. The EIA set-up jumpers on the CPU don't match the terminal configuration.

^{*} Indicates an indeterminate condition.

Table 9-2 Problems Indicated by System LEDs

LED	Condition	Possible Problem
Front Panel:		
DC ON	OFF	+5 Vdc not present
	BLINKING	CPU voltage or voltages out of tolerance
RUN PROC	ON OFF	A defective terminal, terminal cable, or serial line unit.
PROC RUN	ON OFF	Processor has powered-up to a micro-loop, possibly due to a defective battery backup unit (if present) defective memory, or a defective power supply.
RUN PROC	ON	CPU disregarded setting of HALT switch indicating a defective front panel or front panel cable. Check to be sure the HALT/CONT/BOOT switch is in the HALT position and the keyswitch is in the local position.
CPU Module:		
CLK	OFF	A defective CPU module, CPU chip, or power supply.
Memory Module:	.	
GREEN	OFF	Indicates a lack of +5 B on the memory module. This may be caused by a blown fuse on the memory module or a defective power supply.
RED	ON	A defective memory module or a memory voltage problem.

NOTE

The PDP-11/24 is only capable of EIA operation.

- d. The terminal cabling.
 - If hardwired to the CPU, the terminal should connect to the CPU through a null-modem cable, BC22-A or equivalent.
 - 2) A bad terminal cable, which can be checked by shorting pins 2 and 3 of the terminal's cable. The terminal should now echo characters typed at it. If not, the problem lies in the terminal cable or its associated cabling.
- e. Faulty serial line logic on the CPU module (M7133).
 This can be checked by performing the following steps:
 - 1) Place S5 of E124 in the ON position.
 - 2) Type a 'U' at the terminal. An '*' should be echoed.
 - 3) Type an '*' at the terminal. A 'U' should be echoed.

If the characters are not echoed the fault lies in the SLU logic. If the characters are echoed the PDP-11 processor on the CPU module is defective.

- 4) Place S5 of E124 in the OFF position.
- 5) Proceed to Test 7 to further isolate the problem.

TEST 7:

While watching the front panel RUN light type a $\langle \text{space} \rangle$ at the console terminal. If the character was received by the 11/24 the RUN light will flash once.

The terminal display should now be:

@?

a

If the RUN light did not flash, the terminal is not getting through to the PDP-11/24 CPU chip.

TEST 8:

Type '0/' at the console terminal. The terminal should now be displaying:

For MS11-L memory, nnnnnn will most likely be 000000, although different numbers do not necessarily indicate a problem. Proceed to Test 9 if the terminal output is reasonable.

If the terminal display is:

@Ø/? @

The 11/24 has failed to access memory location 00 000 000. This may be due to an incorrect set-up of the switches on the memory module(s), or a number of the previously mentioned problems.

TEST 9:

The CPU now has memory location \emptyset opened. Type '177777' followed by <return>. 177777 will be deposited as the new contents of location \emptyset . The terminal display should now be:

@Ø/nnnnnn_177777 @

Type '/'. The terminal should now display:

@/177777_

This indicates that the data pattern has been correctly read from memory. If the response is correct, proceed to Test 10. If the response is not correct a failure in the data paths, memory, UNIBUS, or CPU, of the machine is indicated. To further isolate the problem, type <return> followed by '765132/'. The terminal should display:

@765132/177777

The data is now being read from the CPU diagnostic ROM. If the same bits are still missing, the fault lies either in the UNIBUS data lines or the CPU.

TEST 10:

Type '0' followed by return. This changes the contents of location \emptyset to $\emptyset\emptyset\emptyset\emptyset\emptyset\emptyset$. Type '/'. The terminal should now display:

@/177777_Ø @/ØØØØØØ__

If the expected response is received, proceed to Test 11. Any difference in the response indicates an error in the data paths of the machine. The data paths can be checked further typing a <return> followed by '765144/'. The terminal should now display:

@765144/ØØØØØØ

The data is now being read from the CPU diagnostic ROM. If the same bits are still incorrect, the fault is with either the UNIBUS data lines or the CPU.

TEST 11:

The previous tests have partially verified that the PDP-11/24 memory subsystem is working and that the CPU path to memory is functional. It is now time to load into memory and run a very short program. Type <return>. If the 11/24 replies with a '?', disregard it. Next, type the underlined text listed below.

```
@4/nnnnn 6<LF>
000006/nnnnn 1 0<LF>
0000010/nnnnnn 12<LF>
000012/nnnnn 0<CR>
@ 1000/nnnnnn 776<LF>
001004/nnnnn 0<CR>
@ R6/nnnnn 1000<CR>
@ 1000G
001000
0
```

Immediately after the 'G' was typed the RUN LED should flash once and the console terminal should display the text shown. If this test ran successfully, proceed to Test 12. If the console displays nothing after the 'G' was typed, and the RUN and PROC LEDs are ON, the CPU HALT logic is defective. Before attempting to locate the problem make sure the HALT/CONT/BOOT switch is in the HALT position and the keyswitch is in the LOCAL position.

TEST 12:

Place the HALT/CONT/BOOT switch in the CONT position. No action should occur. Type 'P' at the console terminal. The RUN and PROC LEDs should both be lit and the console should now display:

ØØ1ØØØ @P

If the terminal display is correct, proceed to Test 13.

Three possible faults are:

1. Terminal display:

ØØ1ØØØ @P ØØ1ØØ2 The CPU HALT logic is defective and will not permit the CPU to run. The trouble could be with the front panel, cabling, or the CPU.

2. Terminal display:

ØØ1ØØØ @P ØØØØ1Ø @

The CPU serviced a bus error during execution of the program. Examine memory locations 1000 and 1002 to make sure they contain 000240 and 000776 respectively. If so, this is probably a CPU problem.

3. Terminal display:

001000 0P 000014

The CPU serviced a reserved instruction trap during execution of the program. Examine memory locations 1000 and 1002 to ensure they contain 000240 and 000776 respectively. If so, this probably reflects a CPU error.

TEST 13:

The CPU is now running the simple program loaded in memory. Momentarily press the 'BREAK' key on the console terminal. The terminal should now display:

nnnnnn @

The address represented by nnnnnn should be either 001000 or 001002. Any other address represents a fault. Examine the program to verify that memory still contains the correct instructions. If so, the CPU may be at fault.

Failure of the 11/24 to halt may be due to the terminal not sending the 'BREAK' character or the failure of SLU1 to detect the break. The failure may also be any of those failures discussed under Test 11. Proceed to Test 14 to further isolate any faults.

TEST 14:

Type 'P' at the console terminal. The RUN and PROC LEDs should be lit and the console should display:

@P

Place the HALT/CONT/BOOT switch in the HALT position. The RUN and PROC LEDs should go off and the console terminal should display:

nnnnnn @

The address represented by nnnnnn should once again be 001000 or 001002. Any other address represents the same failure discussed in Test 13.

If the CPU can be halted via the front panel switch but not via the 'BREAK' key on the console terminal, the problem is in either the terminal's BREAK generation logic or the 11/24's BREAK detection logic.

TEST 15:

Place the keyswitch in the LOC DSBL position. Type 'P' at the console terminal. The RUN and PROC LEDs should light and the console terminal should display:

@P

If the RUN light flashes and the console displays:

@P Ø01002 (or 001000) a

The error is most likely a defective front panel or improper set-up of the jumpers on the front panel, inhibiting the panel-lock function.

TEST 16:

The CPU should now be functional to the point that it is able to run the diagnostic contained in the M9312 diagnostic ROM. Return the keyswitch to the LOCAL position. The 11/24 should halt and the console should print the ODT prompt.

Return the HALT/CONT/BOOT switch to the CONT position.

The M9312 diagnostic may now be started by typing '165006G' at the console. The RUN and PROC LEDs should light. The diagnostic takes approximately 6 seconds per 128K words of memory.

After the diagnostic has run the console terminal should display:

@165006G sssssss 165006 @ The 22-bit octal address represented by ssssssss is the last address plus 2 found (to be working) during the memory diagnostic. It should conform to the expected memory size of the system. See Section 1.3.8 for details.

If the 11/24 halts at any other address, it indicates a fault. The HALT instructions contained in the M9312 are detailed in Table 9-3.

Certain errors cause the console to be unable to print. The state of the diagnostic may then be determined by examining the Display Register LEDs on the CPU module (M7133). They indicate the state of the diagnostic as detailed in Table 3-14.

TEST 17:

At this point, the 11/24 should be able to boot the XXDP+ diagnostic medium. Place the XXDP+ media in the drive and perform the correct bootstrap procedure. If the media boots, you may then proceed to run XXDP+ diagnostics. If not, the problem may be in the specific peripheral device or the DMA logic of the processor.

If the optional M7134 UNIBUS Map module is installed, it may be removed and a bootstrap program toggled in. This may allow the 11/24 to be bootstrapped. The toggle-in boots may be found in the XXDP+ pocket reference card (??-????-??).

9.2 MAINDEC DIAGNOSTIC PROGRAMS
The MAINDEC diagnostics are external programs which are listed in Table 9-4. These programs are loaded and executed with the MAINDEC diagnostic package XXDP+. This package includes monitor programs, device driver programs and utility programs for the CPU and peripheral devices.

Diagnostics 1 through 7 should be executed in the sequence as listed to obtain the proper results. Each diagnostic test assumes the successful completion of the preceding test.

Table 9-3 M9312 Halt Errors

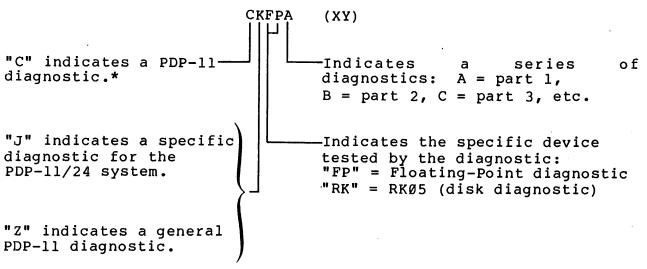

Error	Address	Cause
Bad Address	165142	This error is caused by trapping to location 4 at anytime prior to executing the memory test on the first 4K of memory.
CPU Error	165144	This error indicates a failure with either the base instruction set or the EIS instruction set.
Memory Error	165542	This error indicates a memory system failure.
SLU Error	165702	This HALT indicates a data error in the console SLU.

Table 9-4 PDP-11/24 MAINDEC Diagnostic Programs

MAINDEC Diagnostic	Operating Sequence	Title
CJKDB <xy></xy>	1	11/24 CPU
CJKDA <xy></xy>	2	KTF11-A Memory Management

9.2.1 Diagnostic Designations
The designations assigned to the PDP-11 family of diagnostic programs are described as follows.

* Not used as part of the diagnostic filename on diagnostic disk pack or on magnetic tape.

The "xy" designation that appears after the MAINDEC diagnostic listing on the table contains the following information.

9.2.2 Running Diagnostics
For a detailed explanation of how to run each diagnostic, refer to the appropriate diagnostic documentation.

The following paragraphs list each diagnostic, which diagnostics should be successfully completed before running the specified diagnostic, and the switch register bits and their use. The switch register referred to is a software switch register maintained at memory location 000 176_8 .

9.2.2.1 CJKDB - PDP-11/24 CPU Diagnostic -- Prerequisites - none.

Switch Register Bits	Octal Designation	Use
<15>	100000	Halt on error
<13>	020000	Inhibit error printout
<01>	000002	CIS chip set present
<00>	000001	Skip traps test

Bits $\langle 14, 12:02 \rangle$ are not used.

NOTE: Bit 15 and 13 only effect part 3 of the CPU diagnostic. Parts 1 and 2 always halt on an error.

9.2.2.2 CJKDA - KTF11-A Memory Management Diagnostic -- Pre-requisites - CJKDB and the PDP-11/24 Diagnostic ROM

Switch Register Bits	Octal Designation	Use
<15>	100000	Halt on error
<14>	040000	Loop on test
<13>	020000	Inhibit error type outs
<12>	010000	Inhibit Trace Trap
<11>	004000	Inhibit subtest iteration
<10>	002000	Bell on error

<09>	001000	Loop	on	error	.		
<08>	000400	Loop	on	test	in	bits	<7:Ø>
<07:00>		Test	nur	nber			

9.2.2.3 CJKDF - 11/24 Option Diagnostic -- Prerequisites - CJKDB and a turnaround jumper installed on SLU2.

Switch Register	Octal	••
Bit	Designation	Use
<15>	100000	Halt on error
<14>	040000	Scope loop
<13>	020000	Inhibit error type out
<10>	ØØ2ØØØ	Inhibit error flags test
<09>	001000	Loop on error
<07>	000200	Disable SLUZ test
<06>	000100	Inhibit LTC tests
<05>	000040	Inhibit all SLU tests
<04>	000020	Inhibit SLUl testing
<03>	000010	Inhibit SLU2 testing

Bits $\langle 12:11, 8, \emptyset2:\emptyset\emptyset \rangle$ are not used.

9.2.2.4 CZM9B - M9312, 11/24, 11/44 UBI Boot Diagnostic

Switch Register Bit	Octal Designation	Use
<15>	100000	Halt on error
<13>	020000	Inhibit error type outs
<10>	ØØ2ØØØ	Bell on error

Bits $\langle 12:11, 09:00 \rangle$ are not used.

9.2.2.5 CKKUA - 11/24, 11/44 UBI Map Diagnostic -- Prerequisites - KT24 Map Option (M7134), CJKDB and CJKDA.

Switch Register Bit	Octal Designation	Use
<15>	100000	Halt on error
<14>	040000	Loop on test
<13>	020000	Inhibit error type outs
<12>	Ø1ØØØØ	Inhibit Trace Trap
<11>	004000	UNIBUS Memory Trap
<10>	002000	Bell on error
<09>	001000	Loop on error
<08>	000400	Loop on test in bits <5:0>
<07>	000200	Inhibit multiple error type
		outs
<06>		Unused
<05:00>	ØØØØXX	Select UNIBUS memory tests

9.2.2.6 CZMSD - MS11L/M Memory Diagnostic -- Prerequisites - CJKDB, CJKDA and CKKUA.

Switch Register Bit	Octal Designation	Use	
<15> <14>	100000	Halt on error	
	040000	Loop on test	
<13>	020000	Inhibit error type outs	
<12>	010000	Inhibit relocation	
<11>	004000	Quick verify	
<10>	002000	Bell on error	
<09>	001000	Loop on error	
<08>	000400	Halt program	
<07>	000200	Detailed error reports	
<06>	000100	Inhibit configuration map	
<05>	000040	Limit maximum errors per band	
<04>	000020	Wide terminal (132 columns or	
		more)	
<03>	000010	Test mode	
<02>	ØØØØØ 4	Test mode	
<01>	ØØØØØ2	Test mode	
<00>	000001	Detect single bit errors	

9.2.2.7 DZKAQ - PDP-11 Power-Fail Diagnostic

Switch Register Bit	Octal Designation	Use
<15>	100000	Set = Halt at end of test pass
<14>	040000	Set = Disable error type outs Clear = Enable error type outs

Bits <13:00> are not used

9.2.2.8 CKJDC, CJKDD - KEF11-A FP Diagnostic Part 1 and 2 -- Prerequisites - CJKDB, CJKDA, KEF11-A chip set.

Switch Register	Octal	
Bit	Designation	Use
<15>	100000	Halt on error
<14>	040000	Loop on current test
<13>	020000	Inhibit error type outs
<12>	Ø1ØØØØ	Inhibit T-bit trapping
<11>	004000	Inhibit iterations
<10>	002000	Ring bell on error
<09>	001000	Loop on error
<Ø8>	001000	Loop on test in bits <6:0>
<07>		Unused
<06:00>		Test number

9.2.2.9 CJKDH - KEF11-B CIS Diagnostic -- Prerequisites - CJKDB, CZMSD, CJKDF and the KEF11-B chip set.

Switch Register Bit	Octal Designation	Use
<15>	100000	Halt on error
<14>	040000	Scope loop
<12>	010000	Inhibit subtest iterations
<05>	000040	Test CIS Control Chip 9
< Ø 4 >	000020	Test CIS Control Chip 8
<03>	000010	Test CIS Control Chip 7
<02>	ØØØØØ4	Test CIS Control Chip 6
<01>	000002	Test CIS Control Chip 5
<00>	000001	Test CIS Control Chip 4

Bits <11:06> are not used

If bit $\langle 5:\emptyset \rangle$ are not set, the diagnostic checks all 6 chips.

The Communications (Comm) Regulator (Part 5413764) produces two voltages, +15 V and -15 V, that are used by the CPU and optional communication devices in the PDP-11/24. The following paragraphs contain functional and detailed descriptions of the comm regulator circuitry.

A.1 FUNCTIONAL DESCRIPTION

Figure A-l is a functional block diagram of the comm regulator. For purposes of discussion the comm regulator is divided into two parts: the +15 V circuit and the -15 V circuit.

In the +15 V circuit, the pass switch, filter and controller form a closed loop circuit that produces +15 V from an unregulatedd raw dc voltage (25-48 V). The current limiting circuit protects the +15 V circuit from a current overload and the voltage crowbar circuit protects the load from excessively high voltage at the filter output due to a +15 V circuit malfunction.

The -15 V circuit is similar to the +15 V circuit.

A.2 +15 V CIRCUIT DETAILED DESCRIPTION

The pass switch (Q2) is repeatedly turned on and off generating a pulse train across D7 at the LC filter input (L1, C7, C8 and C9). When current flows through D5 and D6, the pass switch is turned on and the raw dc voltage appears across D7. Diode D7 is forward biased when the pass switch is turned off, clamping the filter input to approximately -1 V. The output voltage of the filter is equal to the time averaged (dc) value of the voltage across D7.

The magnitude of the raw dc voltage and the conduction time of the pass switch determine the filter output voltage. The filter output voltage is fed back to the controller that regulates the filter output to +15 V by varying the conduction time of the pass switch. The major components of the controller are operational amplifier E1, and the 555 timer E2.

Amplifier El compares approximately 1/3 of the filter output to a 5.1 V zener reference and amplifies the difference. The amplifier output is an error voltage which increases (decreases) as the output decreases (increases).

The output of the controller is generated by the 555 timer, E2, and is synchronized to the H777 master clock signal which is a \emptyset to +12 V squarewave with a period of 50 us.

When the clock signal goes high, Q7 is momentarily turned on and the timer is first reset and then triggered. Once triggered, the timer output at E2 pin 3 is latched to +12 V producing a current in R20, D5 and D6, and the pass switch turns on. Triggering E2 also turns off its internal discharge transistor at E2 pin 7 and

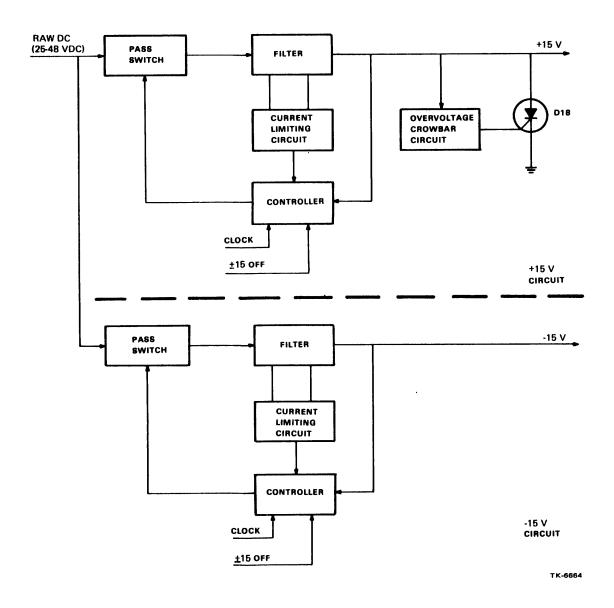

Figure A-1 Comm Regulator Block Diagram

C8 charges towards +15 V along a fixed exponential curve. When the voltage at E2 pin 6 equals the error voltage at E2 pin 5, the timer is reset. (E2 pin 3 goes low, the pass switch turns off, and the voltage across C8 is clamped to approximately .6 V, because the discharge transistor is on.) The conduction time of the pass switch increases (decreases) as the error voltage increases (decreases).

Note that if the error voltage is very high, the timer is not reset until Q6 turns on. The timer does not react to a trigger input at E2 pin 2 until the trailing (rising) edge of the reset input at E2 pin 4. Therefore, when the clock goes high the timer is first reset (ensuring an end to the previous timer cycle) and then triggered (starting a new timer cycle).

Transistors Q4, Q5, and Q6 are the major components of the current limiting circuit that protects the +15 V circuitry from a current The inductor current and the voltage drop across R8 overload. increase when the pass switch is on and decrease when the pass If the inductor current reaches approximately 8.8A switch is off. during pass switch on time, the voltage drop across R8 sufficient to turn on Q4; subsequently Q5 and Q6 also turn on. The error voltage at E2 and pin 5 is clamped to approximately .6 V and is lower than the voltage at E2 pin 6, so the timer is reset. The pass switch is turned off and the peak inductor current is limited to approximately 8.8A. The current output to the load is limited to approximately 6A and the output voltage decreases. Waveforms that apply to the +15 V current limiting circuit are shown in Figure A-2.

Zener diode D14 and SCRs D12 and D13 are the major components of the overvoltage crowbar circuit which protects the +15 V load from an excessively high voltage at the filter output (i.e., raw dc appearing at the filter output due to a pass switch failure).

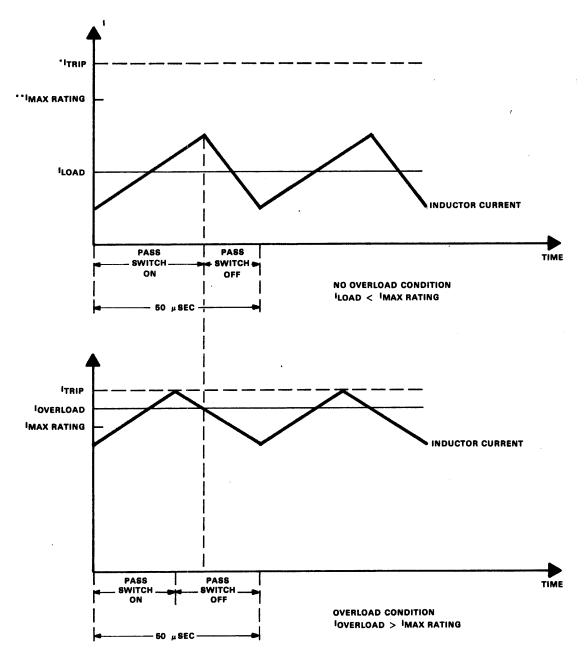

If the filter output becomes higher than approximately 17 V, D14 conducts and the voltage difference between the output voltage and the zener voltage (17 V) appears across R16. Current flows to the gate of D13 so that D13 and, subsequently, D12 are fired. Once D12 is fired, the output load current is bypassed to ground and the ouput voltage is clamped to approximately 1.6 V.

SCR (D12) conducts until its anode current falls below approximately 75 mA for approximately 50 us.

A.3 -15 V CIRCUIT DETAILED DESCRIPTION

The pass switch, filter and controller form a closed loop circuit that produces a regulated $-15\ V$ from an unregulated raw dc voltage (25-48 V).

The pass switch (Q9) is repeatedly turned on and off, generating a pulse train across L2. When current flows into the base of Q11, the pass switch is turned on and the raw dc voltage appears across L2. Diode D24 is reverse biased, the inductor current increases,

[&]quot;ITRIP IS THE VALUE OF THE INDUCTOR CURRENT AT WHICH THE CURRENT LIMITING CIRCUIT TURNS OFF THE PASS SWITCH

MA-0017

Figure A-2 Overcurrent Limiting Waveforms

^{*}IMAX RATING IS THE MAXIMUM CURRENT THAT CAN BE SUPPLIED TO THE LOAD WITHOUT , CAUSING THE PASS SWITCH TO TURN OFF PREMATURELY.

and current to the load is provided by C27, C23 and C28. When the pass switch is turned off, D24 is forward biased and the inductor current flows into the load.

The voltage magnitude at the filter output is determined by the magnitude of the raw dc voltage and the conduction time of the pass switch.

The filter output voltage is fed back to the controller which regulates the filter output at -15 V by varying the conduction time of the pass switch. The major components of the controller are operational amplifier E4 and the 555 timer E3.

Amplifier E4 compares the filter ouput voltage to a -5.1 V reference generated across D19, and amplifies the difference. Zener diode D20 (Vz = 5.6 V) acts as a level shifter. The control voltage at E3 pin 5 has a positive polarity, while the op amp output varies around the -5 V level. The control voltage increases (decreases) as the filter output voltage becomes less (more) negative.

The controller output is generated by E3 and is synchronized to the clock signal which is a \emptyset to +12 V squarewave with a period of 50 us.

When the clock signal goes high, Q7 is momentarily turned on and the timer is first reset and then triggered. Once triggered, the timer output at E3 pin 3 is latched to +12 V producing a current in R38 which is bypassed to ground via Q12 during the time that the clock signal is high (Q12 turned on). Triggering E3 also turns off the internal discharge transistor at E3 pin 7 and C23 charges towards +15 V along a fixed exponential curve. When the voltage at E3 pin 6 equals the control voltage at E3 pin 5, the timer is reset. (E3 pin 3 goes low and C23 is clamped to approximately 0.6 V because the discharge transistor is on.) Current flows into the base of Qll, and the pass switch is turned on from the time the clock signal goes low until E3 is reset. conduction time of the pass switch increases (decreases) as the control voltage increases (decreases). Note that if the control voltage is very high, the timer is not reset until Q7 is turned The timer does not react to a trigger input at E3 pin 2 until the trailing (rising) edge of the reset input at E3 pin 4. Therefore, when the clock goes high, the timer is first reset (ensuring an end to the previous timer cycle) and then triggered (starting a new timer cycle).

During each 50 us clock cycle, the conduction time of the pass switch is between 0 and 25 us; the exact time is dependent on the control voltage.

Transistor Q13 is the major component of the current limiting circuit which protects the -15 V circuitry from a current overload. The inductor current and the voltage across R46

increase when the pass switch is on and decrease when the pass switch is off. If the inductor current reaches approximately 7.5 A during pass switch on time, the voltage across R46 is sufficient to turn on Q13. The control voltage at E3 pin 5 is clamped to approximately $\emptyset.6$ V and is lower than the voltage at E3 pin 6, so the timer is reset. The pass switch is turned off and the peak inductor current is limited to approximately 7.5 A. As the overload increases towards 7.5 A, the conduction time of the pass switch is decreased and the filter output voltage becomes less negative. Waveforms that apply to the -15 V current limiting circuit are shown in Figure A-2.

B-l Instruction Set
Table B-l contains the instruction set of the FPP. Some of the symbology may not be familiar. Therefore, a brief description follows.

1. A bit in the FPS register, designated FD, determines whether single- or double-precision floating-point format is specified. If the flip-flop is cleared, single-precision is specified and is designated by F. If the flip-flop is set, doudle-precision is specified and is designated by D. Examples are NEGF, NEGD, and SUBD.

NOTE

Only the assembler or compiler differentiates between NEGF and NEGD or LDCID or LDCLD instructions. The Floating-point does not differentiate between the instructions but depends upon the value of FD and FL as usually controller by SETD, SETF, SETC, and SETI instructions (i.e., SETD, SETI -> LDCID, SETD, SETL -> LDCLD).

- 2. FPS bit designated FL, determines whether short-integer or long-integer format is specified. If the flip-flop is cleared, short-integer format is specified and is designated by I. If the flip-flop is set, long-integer format is specified and is designated by L. Examples are SETI and SETL.
- 3. Several convert-type instructions use the symbology defined below.
 - $^{\rm C}_{\rm IL}$, $^{\rm FD}$ Convert integer long to floating double. $^{\rm CFD}$, $^{\rm C}_{\rm FD}$, or $^{\rm D}_{\rm F}$ Convert single-floating to double-floating or convert double-floating to single-floating.
- 4. UPLIM is defined as the largest possible number that can be represented in floating-point format. This number has an exponent of 377 (excess 200 notation) and a fraction of all ls. Note the UPLIM is dependent on the format specified. LOLIM is defined as the smallest possible number that is not identical to 0. This number has an exponent of 001 and a fraction of all 0s except for the hidden bit.
- 5. The following conventions are used when referring to address locations.

(xxxx) = the contents of the location specified by xxxx.
ABBS (address) = absolute value of (address)

EXP (address) = exponent of (address) in excess 200 notation.

6. Some of the octal codes listed in Table 6-4 are in the form of mathematical expressions.

Example 1: LDFPS Instruction

Mode 3, register 7 specified (F instruction format)

170100 + SRC SRC field is equal to 37 Basic op code is 170100

SRC and basic op code are added to yeild 170137.

Example 2: LDF Instruction

FAC2, mode 2, and register 6 specified (F1 instruction format).

172400 + FAC * 100 + FSRC

FAC = 2

2 * 100 = 200

172400 + 200 = 172600FSRC is equal to 26

172600 + 26 + 172626

7. AC v l means that the accumulator field (bits 6 and 7 in formats Fl and F3) is logically ORed with 01.

Example:

Accumulator field = bits 6 and 7 = AC2 = 10. AC v 1 = 11.

The information in Table 7-4 is expressed in symbolic notation to provide the reader with a quick reference to the function of each instruction. The following paragraphs supplement the information in Table B-1.

Table B-1 FPP Instruction Set

Mnemo	onic	Instruction Description	Octal Code

C.1 MODULE UTILIZATION

Figure C-l shows the module utilization of the PDP-11/24 processor backplane. The following constraints apply to the use of the PDP-11/24 processor backplane.

- o M9312 Bootstrap/Terminator Module or UNIBUS cable must only be installed in slot 9.
- o NPR (DMA) options must only be installed in slots 7 or 8.
- o Non-NPR options must only be installed in slots 3, 4, 5, 6, or 9.
- o All empty slots, except slot 2, must have grant cards. Slots 7 and 8 must have a double height grant card (G7273) in rows C and D.

Slots 3, 4, 5, 6, and 9 may use a single height grant card (G727A or G7270) in row D or a double height grant card in rows C and D.

C.2 STANDARD, MODIFIED AND EXTENDED BACKPLANE LOCATIONS Figure C-2 shows the pin designations of the standard, modified and extended UNIBUS connectors. The modified and extended UNIBUS differ from the standard UNIBUS in that certain pins have been redesignated. Some ground connections, BUS GRANT signals, and the NPR signal have been removed from the modified and extended UNIBUS and have been redesignated with battery backup voltage pins for MOS memory, parity signal pins, several reserved pins, and test point pins.

Dual-height modules that are standard UNIBUS compatible must not be placed in the modified or extended UNIBUS sections.

C.3 SPC BACKPLANE LOCATIONS

The small peripheral control sections (Figure C-1) collectively contain all the UNIBUS lines as well as power voltages (+5 V, +15 V, -15 V). These sections can be used by hex-height or quad-height modules containing the control logic for peripheral devices. Figure C-3 shows the pin designations for the SPC connectors.

C.4 NPG JUMPER LEAD ROUTING

The NPG line is the UNIBUS grant line for devices that perform data transfers without processor intervention. Continuity of the NPG line is provided by wire jumpers on the backplane with the exception of slots 1, 2, 7 and 8 (slot 1 holds the processor module and slot 2 holds the KT24 map option or memory). Slots 7 and 8 must have a G7273 double-height grant card in rows C and D when an NPR device is not installed. When an NPR device is installed in a slot other than slot 7 or 8, the corresponding

jumper wire from pin CAl to pin CBl of that slot must be removed. The routing of the NPG signal through the backplane is shown in Figure C-4.

NOTE

If an NPR device is removed from a slot a double-height grant card (G7273) must be installed or the jumper wire from CAl to CBl must be reconnected.
